For sheer predictive genius look no further prophecy-watchers than the Bill Gates-funded Event 201 held only six weeks before the 'coronavirus pandemic' is supposed to have broken out in China and Event 201 was based on a scenario of a global 'coronavirus pandemic'. Melinda Gates, the great man's missus, told the BBC that he had 'prepared for years' for a coronavirus pandemic which told us what we already knew. Nostradamugates had predicted in a TED talk in 2015 that a pandemic was coming that would kill a lot of people and demolish the world economy. My god, the man is a machine – possibly even literally. Now here he was only weeks before the real thing funding just such a simulated scenario and involving his friends and associates at Johns Hopkins, the World Economic Forum Cult-front of Klaus Schwab, the United Nations, Johnson & Johnson, major banks, and officials from China and the Centers for Disease Control in the United States. What synchronicity – Johns Hopkins would go on to compile the fraudulent 'Covid' figures, the World Economic Forum and Schwab would push the 'Great Reset' in response to 'Covid', the Centers for Disease Control would be at the forefront of 'Covid' policy in the United States, Johnson & Johnson would produce a 'Covid vaccine', and everything would officially start just weeks later in China. Spooky, eh? They were even accurate in creating a simulation of a 'virus' pandemic because the 'real thing' would also be a simulation. Event 201 was not an exercise preparing for something that might happen; it was a rehearsal for what those in control knew was *going* to happen and very shortly. Hours of this simulation were posted on the Internet and the various themes and responses mirrored what would soon be imposed to transform human society. News stories were inserted and what they said would be commonplace a few weeks later with still more prophecy perfection. Much discussion focused on the need to deal with misinformation and the 'anti-vax movement' which is exactly what happened when the 'virus' arrived – was said to have arrived – in the West.

Cult-owned social media banned criticism and exposure of the official 'virus' narrative and when I said there *was* no 'virus' in early April, 2020, I was banned by one platform after another including YouTube, Facebook and later Twitter. The mainstream broadcast media in Britain was in effect banned from interviewing me by the Tony-Blair-created government broadcasting censor Ofcom headed by career government bureaucrat Melanie Dawes who was appointed just as the 'virus' hoax was about to play out in January, 2020. At the same time the Ickonic media platform was using Vimeo, another ultra-Zionist-owned operation, while our own player was being created and they deleted in an instant hundreds of videos, documentaries, series and shows to confirm their unbelievable vindictiveness. We had copies, of course, and they had to be restored one by one when our player was ready. These people have no class. Sabbatian Facebook promised free advertisements for the Gates-controlled World Health Organization narrative while deleting 'false claims and conspiracy theories' to stop 'misinformation' about the alleged coronavirus. All these responses could be seen just a short while earlier in the scenarios of Event 201. Extreme censorship was absolutely crucial for the Cult because the official story was so ridiculous and unsupportable by the evidence that it could never survive open debate and the free-flow of information and opinion. If you can't win a debate then don't have one is the Cult's approach throughout history. Facebook's little boy front man – front boy – Mark Zuckerberg equated 'credible and accurate information' with official sources and exposing their lies with 'misinformation'.

Silencing those that can see

The censorship dynamic of Event 201 is now the norm with an army of narrative-supporting 'fact-checker' organisations whose entire reason for being is to tell the public that official narratives are true and those exposing them are lying. One of the most appalling of these 'fact-checkers' is called NewsGuard founded by ultra-Zionist Americans Gordon Crovitz and Steven Brill. Crovitz is a former publisher of *The Wall Street Journal*, former Executive Vice President of Dow Jones, a member of the Council on Foreign Relations (CFR), and on the board of the American Association of Rhodes Scholars. The CFR and Rhodes Scholarships, named after Rothschild agent Cecil Rhodes who plundered the gold and diamonds of South Africa for his masters and the Cult, have featured widely in my books. NewsGuard don't seem to like me for some reason – I really can't think why – and they have done all they can to have me censored and discredited which is, to quote an old British politician, like being savaged by a dead sheep. They are, however, like all in the censorship network, very well connected and funded by organisations themselves funded by, or connected to, Bill Gates. As you would expect with anything associated with Gates NewsGuard has an offshoot called HealthGuard which 'fights online health care hoaxes'. How very kind. Somehow the NewsGuard European Managing Director Anna-Sophie Harling, a remarkably young-looking woman with no broadcasting experience and little hands-on work in journalism, has somehow secured a position on the ‘Content Board’ of UK government broadcast censor Ofcom. An executive of an organisation seeking to discredit dissidents of the official narratives is making decisions for the government broadcast ‘regulator’ about content?? Another appalling ‘fact-checker’ is Full Fact funded by George Soros and global censors Google and Facebook.

It’s amazing how many activists in the ‘fact-checking’, ‘anti-hate’, arena turn up in government-related positions – people like UK Labour Party activist Imran Ahmed who heads the Center for Countering Digital Hate founded by people like Morgan McSweeney, now chief of staff to the Labour Party’s hapless and useless ‘leader’ Keir Starmer. Digital Hate – which is what it really is – uses the American spelling of Center to betray its connection to a transatlantic network of similar organisations which in 2020 shapeshifted from attacking people for ‘hate’ to attacking them for questioning the ‘Covid’ hoax and the dangers of the ‘Covid vaccine’. It’s just a coincidence, you understand. This is one of Imran Ahmed’s hysterical statements: ‘I would go beyond calling anti-vaxxers conspiracy theorists to say they are an extremist group that pose a national security risk.’ No one could ever accuse this prat of understatement and he’s including in that those parents who are now against vaccines after their children were damaged for life or killed by them. He’s such a nice man. Ahmed does the rounds of the Woke media getting soft-ball questions from spineless ‘journalists’ who never ask what right he has to campaign to destroy the freedom of speech of others while he demands it for himself. There also seems to be an overrepresentation in Ofcom of people connected to the narrative-worshipping BBC. This incredible global network of narrative-support was super-vital when the ‘Covid’ hoax was played in the light of the mega-whopper lies that have to be defended from the spotlight cast by the most basic intelligence.

Setting the scene

The Cult plays the long game and proceeds step-by-step ensuring that everything is in place before major cards are played and they don't come any bigger than the 'Covid' hoax. The psychopaths can't handle events where the outcome isn't certain and as little as possible – preferably nothing – is left to chance. Politicians, government and medical officials who would follow direction were brought to illusory power in advance by the Cult web whether on the national stage or others like state governors and mayors of America. For decades the dynamic between officialdom, law enforcement and the public was changed from one of service to one of control and dictatorship. Behaviour manipulation networks established within government were waiting to impose the coming 'Covid' rules and regulations specifically designed to subdue and rewire the psyche of the people in the guise of protecting health. These included in the UK the Behavioural Insights Team part-owned by the British government Cabinet Office; the Scientific Pandemic Insights Group on Behaviours (SPI-B); and a whole web of intelligence and military groups seeking to direct the conversation on social media and control the narrative. Among them are the cyberwarfare (on the people) 77th Brigade of the British military which is also coordinated through the Cabinet Office as civilian and military leadership continues to combine in what they call the Fusion Doctrine. The 77th Brigade is a British equivalent of the infamous Israeli (Sabbatian) military cyberwarfare and Internet manipulation operation Unit 8200 which I expose at length in *The Trigger*. Also carefully in place were the medical and science advisers to government – many on the payroll past or present of Bill Gates – and a whole alternative structure of unelected government stood by to take control when elected parliaments were effectively closed down once the 'Covid' card was slammed on the table. The structure I have described here and so much more was installed in every major country through the Cult networks. The top-down control hierarchy looks like this: The Cult – Cult-owned Gates – the World Health Organization and Tedros – Gates-funded or controlled chief medical officers and science 'advisers' (dictators) in each country –

political 'leaders'– law enforcement – The People. Through this simple global communication and enforcement structure the policy of the Cult could be imposed on virtually the entire human population so long as they acquiesced to the fascism. With everything in place it was time for the button to be pressed in late 2019/early 2020.

These were the prime goals the Cult had to secure for its will to prevail:

1) Locking down economies, closing all but designated 'essential' businesses (Cult-owned corporations were 'essential'), and putting the population under house arrest was an imperative to destroy independent income and employment and ensure dependency on the Cult-controlled state in the Hunger Games Society. Lockdowns had to be established as the global blueprint from the start to respond to the 'virus' and followed by pretty much the entire world.

2) The global population had to be terrified into believing in a deadly 'virus' that didn't actually exist so they would unquestioningly obey authority in the belief that authority must know how best to protect them and their families. Software salesman Gates would suddenly morph into the world's health expert and be promoted as such by the Cult-owned media.

3) A method of testing that wasn't testing for the 'virus', but was only claimed to be, had to be in place to provide the illusion of 'cases' and subsequent 'deaths' that had a very different cause to the 'Covid-19' that would be scribbled on the death certificate.

4) Because there was no 'virus' and the great majority testing positive with a test not testing for the 'virus' would have no symptoms of anything the lie had to be sold that people without symptoms (without the 'virus') could still pass it on to others. This was crucial to justify for the first time quarantining – house arresting – healthy people. Without this the economy-destroying lockdown of *everybody* could not have been credibly sold.

5) The 'saviour' had to be seen as a vaccine which beyond evil drug companies were working like angels of mercy to develop as quickly as possible, with all corners cut, to save the day. The public must absolutely not know that the 'vaccine' had nothing to do with a 'virus' or that the contents were ready and waiting with a very different motive long before the 'Covid' card was even lifted from the pack.

I said in March, 2020, that the 'vaccine' would have been created way ahead of the 'Covid' hoax which justified its use and the following December an article in the New York *Intelligencer* magazine said the Moderna 'vaccine' had been 'designed' by

January, 2020. This was 'before China had even acknowledged that the disease could be transmitted from human to human, more than a week before the first confirmed coronavirus case in the United States'. The article said that by the time the first American death was announced a month later 'the vaccine had already been manufactured and shipped to the National Institutes of Health for the beginning of its Phase I clinical trial'. The 'vaccine' was actually 'designed' long before that although even with this timescale you would expect the article to ask how on earth it could have been done that quickly. Instead it asked why the 'vaccine' had not been rolled out then and not months later. Journalism in the mainstream is truly dead. I am going to detail in the next chapter why the 'virus' has never existed and how a hoax on that scale was possible, but first the foundation on which the Big Lie of 'Covid' was built.

The test that doesn't test

Fraudulent 'testing' is the bottom line of the whole 'Covid' hoax and was the means by which a 'virus' that did not exist *appeared* to exist. They could only achieve this magic trick by using a test not testing for the 'virus'. To use a test that *was* testing for the 'virus' would mean that every test would come back negative given there was no 'virus'. They chose to exploit something called the RT-PCR test invented by American biochemist Kary Mullis in the 1980s who said publicly that his PCR test … *cannot detect infectious disease*. Yes, the 'test' used worldwide to detect infectious 'Covid' to produce all the illusory 'cases' and 'deaths' compiled by Johns Hopkins and others *cannot detect infectious disease*. This fact came from the mouth of the man who invented PCR and was awarded the Nobel Prize in Chemistry in 1993 for doing so. Sadly, and incredibly conveniently for the Cult, Mullis died in August, 2019, at the age of 74 just before his test would be fraudulently used to unleash fascism on the world. He was said to have died from pneumonia which was an irony in itself. A few months later he would have had 'Covid-19' on his death certificate. I say the timing of his death was convenient because had he lived Mullis, a brilliant, honest and decent man, would have been vociferously speaking out against the use of his test to detect 'Covid' when it was never designed, or able, to do that. I know that to be true given that Mullis made the same point when his test was used to 'detect' – not detect – HIV. He had been seriously critical of the Gallo/Montagnier claim to have isolated the HIV 'virus' and shown it to cause AIDS for which Mullis said there was no evidence. AIDS is actually not a disease but a series of diseases from which people die all the time. When they die from those *same diseases* after a positive 'test' for HIV then AIDS goes on their death certificate. I think I've heard that before somewhere. Countries instigated a policy with 'Covid' that anyone who tested positive with a test not testing for the 'virus' and died of any other cause within 28 days and even longer 'Covid-19' had to go on the death certificate. Cases have come from the test that can't test for infectious disease and the deaths are those who have died of *anything* after testing positive with a test not testing for the 'virus'. I'll have much more later about the death certificate scandal.

Mullis was deeply dismissive of the now US 'Covid' star Anthony Fauci who he said was a liar who didn't know anything about anything – 'and I would say that to his face – nothing.' He said of Fauci: 'The man thinks he can take a blood sample, put it in an electron microscope and if it's got a virus in there you'll know it – he doesn't understand electron microscopy and he doesn't understand medicine and shouldn't be in a position like he's in.' That position, terrifyingly, has made him the decider of 'Covid' fascism policy on behalf of the Cult in his role as director since 1984 of the National Institute of Allergy and Infectious Diseases (NIAID) while his record of being wrong is laughable; but being wrong, so long as it's the *right kind* of wrong, is why the Cult loves him. He'll say anything the Cult tells him to say. Fauci was made Chief Medical Adviser to the President immediately Biden took office. Biden was installed in the White House by Cult manipulation and one of his first decisions was to elevate Fauci to a position of even more control. This is a coincidence? Yes, and I identify as a flamenco dancer called Lola. How does such an incompetent criminal like Fauci remain in that pivotal position in American health since *the 1980s*? When you serve the Cult it looks after you until you are surplus to requirements. Kary Mullis said prophetically of Fauci and his like: 'Those guys have an agenda and it's not an agenda we would like them to have … they make their own rules, they change them when they want to, and Tony Fauci does not mind going on television in front of the people who pay his salary and lie directly into the camera.' Fauci has done that almost daily since the 'Covid' hoax began. Lying is in Fauci's DNA. To make the situation crystal clear about the PCR test this is a direct quote from its inventor Kary Mullis:

> It [the PCR test] doesn't tell you that you're sick and doesn't tell you that the thing you ended up with was really going to hurt you ...'

Ask yourself why governments and medical systems the world over have been using this very test to decide who is 'infected' with the SARS-CoV-2 'virus' and the alleged disease it allegedly causes, 'Covid-19'. The answer to that question will tell you what has been going on. By the way, here's a little show-stopper – the 'new' SARS-CoV-2 'virus' was 'identified' as such right from the start using … *the PCR test not testing for the 'virus'*. If you are new to this and find that shocking then stick around. I have hardly started yet. Even worse, other 'tests', like the 'Lateral Flow Device' (LFD), are considered so useless that they have to be *confirmed* by the PCR test! Leaked emails written by Ben Dyson, adviser to UK 'Health' Secretary Matt Hancock, said they were 'dangerously unreliable'. Dyson, executive director of strategy at the Department of Health, wrote: 'As of today, someone who gets a positive LFD result in (say) London has at best a 25 per cent chance of it being a true positive, but if it is a self-reported test potentially as low as 10 per cent (on an optimistic assumption about specificity) or as low as 2 per cent (on a more pessimistic assumption).' These are the 'tests' that schoolchildren and the public are being urged to have twice a week or more and have to isolate if they get a positive. Each fake positive goes in the statistics as a 'case' no matter how ludicrously inaccurate and the ‘cases’ drive lockdown, masks and the pressure to ‘vaccinate’. The government said in response to the email leak that the ‘tests’ were accurate which confirmed yet again what shocking bloody liars they are. The real false positive rate is *100 percent* as we’ll see. In another ‘you couldn’t make it up’ the UK government agreed to pay £2.8 billion to California’s Innova Medical Group to supply the irrelevant lateral flow tests. The company’s primary test-making centre is in China. Innova Medical Group, established in March, 2020, is owned by Pasaca Capital Inc, chaired by Chinese-American millionaire Charles Huang who was born in Wuhan.

How it works – and how it doesn’t

The RT-PCR test, known by its full title of Polymerase chain reaction, is used across the world to make millions, even billions, of copies of a DNA/RNA genetic information sample. The process is called ‘amplification’ and means that a tiny sample of genetic material is amplified to bring out the detailed content. I stress that it is not testing for an infectious disease. It is simply amplifying a sample of genetic material. In the words of Kary Mullis: ‘PCR is … just a process that’s used to make a whole lot of something out of something.’ To emphasise the point companies that make the PCR tests circulated around the world to ‘test’ for ‘Covid’ warn on the box that it can’t be used to detect ‘Covid’ or infectious disease and is for research purposes only. It’s okay, rest for a minute and you’ll be fine. This is the test that produces the ‘cases’ and ‘deaths’ that have been used to destroy human society. All those global and national medical and scientific ‘experts’ demanding this destruction to ‘save us’ *KNOW* that the test is not testing for the ‘virus’ and the cases and deaths they claim to be real are an almost unimaginable fraud. Every one of them and so many others including politicians and psychopaths like Gates and Tedros must be brought before Nuremburg-type trials and jailed for the rest of their lives. The more the genetic sample is amplified by PCR the more elements of that material become sensitive to the test and by that I don’t mean sensitive for a ‘virus’ but for elements of the genetic material which is *naturally* in the body or relates to remnants of old conditions of various kinds lying dormant and causing no disease. Once the amplification of the PCR reaches a certain level *everyone* will test positive. So much of the material has been made sensitive to the test that everyone will have some part of it in their body. Even lying criminals like Fauci have said that once PCR amplifications pass 35 cycles everything will be a false positive that cannot be trusted for the reasons I have described. I say, like many proper doctors and scientists, that 100 percent of the 'positives' are false, but let's just go with Fauci for a moment.

He says that any amplification over 35 cycles will produce false positives and yet the US Centers for Disease Control (CDC) and Food and Drug Administration (FDA) have recommended up to *40 cycles* and the National Health Service (NHS) in Britain admitted in an internal document for staff that it was using *45 cycles* of amplification. A long list of other countries has been doing the same and at least one 'testing' laboratory has been using *50 cycles*. Have you ever heard a doctor, medical 'expert' or the media ask what level of amplification has been used to claim a 'positive'. The 'test' comes back 'positive' and so you have the 'virus', end of story. Now we can see how the government in Tanzania could send off samples from a goat and a pawpaw fruit under human names and both came back positive for 'Covid-19'. Tanzania president John Magufuli mocked the 'Covid' hysteria, the PCR test and masks and refused to import the DNA-manipulating 'vaccine'. The Cult hated him and an article sponsored by the Bill Gates Foundation appeared in the London *Guardian* in February, 2021, headed 'It's time for Africa to rein in Tanzania's anti-vaxxer president'. Well, 'reined in' he shortly was. Magufuli appeared in good health, but then, in March, 2021, he was dead at 61 from 'heart failure'. He was replaced by Samia Hassan Suhulu who is connected to Klaus Schwab's World Economic Forum and she immediately reversed Magufuli's 'Covid' policy. A sample of cola tested positive for 'Covid' with the PCR test in Germany while American actress and singer-songwriter Erykah Badu tested positive in one nostril and negative in the other. Footballer Ronaldo called the PCR test ‘bullshit’ after testing positive three times and being forced to quarantine and miss matches when there was nothing wrong with him. The mantra from Tedros at the World Health Organization and national governments (same thing) has been test, test, test. They know that the more tests they can generate the more fake ‘cases’ they have which go on to become ‘deaths’ in ways I am coming to. The UK government has its Operation Moonshot planned to test multiple millions every day in workplaces and schools with free tests for everyone to use twice a week at home in line with the Cult plan from the start to make testing part of life. A government advertisement for an ‘Interim Head of Asymptomatic Testing Communication’ said the job included responsibility for delivering a ‘communications strategy’ (propaganda) ‘to support the expansion of asymptomatic testing that *‘normalises testing as part of everyday life*’. More tests means more fake ‘cases’, ‘deaths’ and fascism. I have heard of, and from, many people who booked a test, couldn’t turn up, and yet got a positive result through the post for a test they’d never even had. The whole thing is crazy, but for the Cult there’s method in the madness. Controlling and manipulating the level of amplification of the test means the authorities can control whenever they want the number of apparent ‘cases’ and ‘deaths’. If they want to justify more fascist lockdown and destruction of livelihoods they keep the amplification high. If they want to give the illusion that lockdowns and the ‘vaccine’ are working then they lower the amplification and ‘cases’ and ‘deaths’ will appear to fall. In January, 2021, the Cult-owned World Health Organization suddenly warned laboratories about over-amplification of the test and to lower the threshold. Suddenly headlines began appearing such as: ‘Why ARE “Covid” cases plummeting?’ This was just when the vaccine rollout was underway and I had predicted months before they would make cases appear to fall through amplification tampering when the ‘vaccine’ came. These people are so predictable.

Cow vaccines?

The question must be asked of what is on the test swabs being poked far up the nose of the population to the base of the brain? A nasal swab punctured one woman's brain and caused it to leak fluid. Most of these procedures are being done by people with little training or medical knowledge. Dr Lorraine Day, former orthopaedic trauma surgeon and Chief of Orthopaedic Surgery at San Francisco General Hospital, says the tests are really a *'vaccine'*. Cows have long been vaccinated this way. She points out that masks have to cover the nose and the mouth where it is claimed the 'virus' exists in saliva. Why then don't they take saliva from the mouth as they do with a DNA test instead of pushing a long swab up the nose towards the brain? The ethmoid bone separates the nasal cavity from the brain and within that bone is the cribriform plate. Dr Day says that when the swab is pushed up against this plate and twisted the procedure is 'depositing things back there'. She claims that among these 'things' are nanoparticles that can enter the brain. Researchers have noted that a team at the Gates-funded Johns Hopkins have designed tiny, star-shaped micro-devices that can latch onto intestinal mucosa and release drugs into the body. Mucosa is the thin skin that covers the inside surface of parts of the body such as *the nose* and mouth and produces mucus to protect them. The Johns Hopkins micro-devices are called 'theragrippers' and were 'inspired' by a parasitic worm that digs its sharp teeth into a host's intestines. Nasal swabs are also coated in the sterilisation agent ethylene oxide. The US National Cancer Institute posts this explanation on its website:

> At room temperature, ethylene oxide is a flammable colorless gas with a sweet odor. It is used primarily to produce other chemicals, including antifreeze. In smaller amounts, ethylene oxide is used as a pesticide and a sterilizing agent. The ability of ethylene oxide to damage DNA makes it an effective sterilizing agent but also accounts for its cancer-causing activity.

The Institute mentions lymphoma and leukaemia as cancers most frequently reported to be associated with occupational exposure to ethylene oxide along with stomach and breast cancers. How does anyone think this is going to work out with the constant testing regime being inflicted on adults and children at home and at school that will accumulate in the body anything that's on the swab?

Doctors know best

It is vital for people to realise that 'hero' doctors 'know' only what the Big Pharma-dominated medical authorities tell them to 'know' and if they refuse to 'know' what they are told to 'know' they are out the door. They are mostly not physicians or healers, but repeaters of the official narrative – or else. I have seen alleged professional doctors on British television make shocking statements that we are supposed to take seriously. One called 'Dr' Amir Khan, who is actually telling patients how to respond to illness, said that men could take the birth pill to 'help slow down the effects of Covid-19'. In March, 2021, another ridiculous 'Covid study' by an American doctor proposed injecting men with the female sex hormone progesterone as a 'Covid' treatment. British doctor Nighat Arif told the BBC that face coverings were now going to be part of ongoing normal. Yes, the vaccine protects you, she said (evidence?) … but the way to deal with viruses in the community was always going to come down to hand washing, face covering and keeping a physical distance. That's not what we were told before the 'vaccine' was circulating. Arif said she couldn't imagine ever again going on the underground or in a lift without a mask. I was just thanking my good luck that she was not my doctor when she said – in March, 2021 – that if 'we are *behaving* and we are doing all the right things' she thought we could 'have our nearest and dearest around us at home … around *Christmas* and N*ew Year!* Her patronising delivery was the usual school teacher talking to six-year-olds as she repeated every government talking point and probably believed them all. If we have learned anything from the 'Covid' experience surely it must be that humanity's perception of doctors needs a fundamental rethink. NHS 'doctor' Sara Kayat told her television audience that the 'Covid vaccine' would '100 percent prevent hospitalisation and death'. Not even Big Pharma claimed that. We have to stop taking 'experts' at their word without question when so many of them are clueless and only repeating the party line on which their careers depend. That is not to say there are not brilliants doctors – there are and I have spoken to many of them since all this began – but you won't see them in the mainstream media or quoted by the psychopaths and yes-people in government.

Remember the name – Christian Drosten

German virologist Christian Drosten, Director of Charité Institute of Virology in Berlin, became a national star after the pandemic hoax began. He was feted on television and advised the German government on 'Covid' policy. Most importantly to the wider world Drosten led a group that produced the 'Covid' testing protocol for the PCR test. What a remarkable feat given the PCR cannot test for infectious disease and even more so when you think that Drosten said that his method of testing for SARS-CoV-2 was developed 'without having virus material available'. *He developed a test for a 'virus' that he didn't have and had never seen*. Let that sink in as you survey the global devastation that came from what he did. The whole catastrophe of Drosten's 'test' was based on the alleged genetic sequence published by Chinese scientists on the Internet. We will see in the next chapter that this alleged 'genetic sequence' has never been produced by China or anyone and cannot be when there *is no* SARS-CoV-2. Drosten, however, doesn't seem to let little details like that get in the way. He was the lead author with Victor Corman from the same Charité Hospital of the paper 'Detection of 2019 novel coronavirus (2019-nCoV) by real-time PCR' published in a magazine called *Eurosurveillance*. This became known as the Corman-Drosten paper. In November, 2020, with human society devastated by the effects of the Corman-Drosten test baloney, the protocol was publicly challenged by 22 international scientists and independent researchers from Europe, the United States, and Japan. Among them were senior molecular geneticists, biochemists, immunologists, and microbiologists. They produced a document headed 'External peer review of the RTPCR test to detect SARS-Cov-2 Reveals 10 Major Flaws At The Molecular and Methodological Level: Consequences

For False-Positive Results'. The flaws in the Corman-Drosten test included the following:

- The test is non-specific because of erroneous design
- Results are enormously variable
- The test is unable to discriminate between the whole 'virus' and viral fragments
- It doesn't have positive or negative controls
- The test lacks a standard operating procedure
- It is unsupported by proper peer view

The scientists said the PCR 'Covid' testing protocol was not founded on science and they demanded the Corman-Drosten paper be retracted by *Eurosurveillance*. They said all present and previous Covid deaths, cases, and 'infection rates' should be subject to a massive retroactive inquiry. Lockdowns and travel restrictions should be reviewed and relaxed and those diagnosed through PCR to have 'Covid-19' should not be forced to isolate. Dr Kevin Corbett, a health researcher and nurse educator with a long academic career producing a stream of peer-reviewed publications at many UK universities, made the same point about the PCR test debacle. He said of the scientists' conclusions: 'Every scientific rationale for the development of that test has been totally destroyed by this paper. It's like Hiroshima/Nagasaki to the Covid test.' He said that China hadn't given them an isolated 'virus' when Drosten developed the test. Instead they had developed the test from *a sequence in a gene bank*.' Put another way … *they made it up*! The scientists were supported in this contention by a Portuguese appeals court which ruled in November, 2020, that PCR tests are unreliable and it is unlawful to quarantine people based solely on a PCR test. The point about China not providing an isolated virus must be true when the 'virus' has never been isolated to this day and the consequences of that will become clear. Drosten and company produced this useless 'protocol' right on cue in January, 2020, just as the 'virus' was said to be moving westward and it somehow managed to successfully pass a peer-review in 24 hours. In other words there was no peer-review for a test that would be used to decide who had ‘Covid’ and who didn’t across the world. The Cult-created, Gates-controlled World Health Organization immediately recommended all its nearly 200 member countries to use the Drosten PCR protocol to detect ‘cases’ and ‘deaths’. The sting was underway and it continues to this day.

So who is this Christian Drosten that produced the means through which death, destruction and economic catastrophe would be justified? His education background, including his doctoral thesis, would appear to be somewhat shrouded in mystery and his track record is dire as with another essential player in the ‘Covid’ hoax, the Gates-funded Professor Neil Ferguson at the Gates-funded Imperial College in London of whom more shortly. Drosten predicted in 2003 that the alleged original SARS ‘virus’ (SARS-1’) was an epidemic that could have serious effects on economies and an effective vaccine would take at least two years to produce. Drosten’s answer to every alleged ‘outbreak’ is a vaccine which you won’t be shocked to know. What followed were just 774 official deaths worldwide and none in Germany where there were only nine cases. That is even if you believe there ever was a SARS ‘virus’ when the evidence is zilch and I will expand on this in the next chapter. Drosten claims to be co-discoverer of ‘SARS-1’ and developed a test for it in 2003. He was screaming warnings about ‘swine flu’ in 2009 and how it was a widespread infection far more severe than any dangers from a vaccine could be and people should get vaccinated. It would be helpful for Drosten’s vocal chords if he simply recorded the words ‘the virus is deadly and you need to get vaccinated’ and copies could be handed out whenever the latest made-up threat comes along. Drosten’s swine flu epidemic never happened, but Big Pharma didn’t mind with governments spending hundreds of millions on vaccines that hardly anyone bothered to use and many who did wished they hadn’t. A study in 2010 revealed that the risk of dying from swine flu, or H1N1, was no higher than that of the annual seasonal flu which is what at least most of ‘it’ really was as in the case of 'Covid-19'. A media investigation into Drosten asked how with such a record of inaccuracy he could be *the* government adviser on these issues. The answer to that question is the same with Drosten, Ferguson and Fauci – they keep on giving the authorities the 'conclusions' and 'advice' they want to hear. Drosten certainly produced the goods for them in January, 2020, with his PCR protocol garbage and provided the foundation of what German internal medicine specialist Dr Claus Köhnlein, co-author of *Virus Mania*, called the 'test pandemic'. The 22 scientists in the *Eurosurveillance* challenge called out conflicts of interest within the Drosten 'protocol' group and with good reason. Olfert Landt, a regular co-author of Drosten 'studies', owns the biotech company TIB Molbiol Syntheselabor GmbH in Berlin which manufactures and sells the tests that Drosten and his mates come up with. They have done this with SARS, Enterotoxigenic E. coli (ETEC), MERS, Zika 'virus', yellow fever, and now 'Covid'. Landt told the *Berliner Zeitung* newspaper:

> The testing, design and development came from the Charité [Drosten and Corman]. We simply implemented it immediately in the form of a kit. And if we don't have the virus, which originally only existed in Wuhan, we can make a synthetic gene to simulate the genome of the virus. That's what we did very quickly.

This is more confirmation that the Drosten test was designed without access to the 'virus' and only a synthetic simulation which is what SARS-CoV-2 really is – a computer-generated synthetic fiction. It's quite an enterprise they have going here. A Drosten team decides what the test for something should be and Landt's biotech company flogs it to governments and medical systems across the world. His company must have made an absolute fortune since the 'Covid' hoax began. Dr Reiner Fuellmich, a prominent German consumer protection trial lawyer in Germany and California, is on Drosten's case and that of Tedros at the World Health Organization for crimes against humanity with a class-action lawsuit being prepared in the United States and other legal action in Germany.

Why China?

Scamming the world with a 'virus' that doesn't exist would seem impossible on the face of it, but not if you have control of the relatively few people that make policy decisions and the great majority of the global media. Remember it's not about changing 'real' reality it's about controlling *perception* of reality. You don't have to make something happen you only have make people *believe* that it's happening. Renegade Minds understand this and are therefore much harder to swindle. 'Covid-19' is not a 'real' 'virus'. It's a mind virus, like a computer virus, which has infected the minds, not the bodies, of billions. It all started, publically at least, in China and that alone is of central significance. The Cult was behind the revolution led by its asset Mao Zedong, or Chairman Mao, which established the People's Republic of China on October 1st, 1949. It should have been called The Cult's Republic of China, but the name had to reflect the recurring illusion that vicious dictatorships are run by and for the people (see all the 'Democratic Republics' controlled by tyrants). In the same way we have the 'Biden' Democratic Republic of America officially ruled by a puppet tyrant (at least temporarily) on behalf of Cult tyrants. The creation of Mao's merciless communist/fascist dictatorship was part of a frenzy of activity by the Cult at the conclusion of World War Two which, like the First World War, it had instigated through its assets in Germany, Britain, France, the United States and elsewhere. Israel was formed in 1948; the Soviet Union expanded its 'Iron Curtain' control, influence and military power with the Warsaw Pact communist alliance in 1955; the United Nations was formed in 1945 as a Cult precursor to world government; and a long list of world bodies would be established including the World Health Organization (1948), World Trade Organization (1948 under another name until 1995), International Monetary Fund (1945) and World Bank (1944). Human society was redrawn and hugely centralised in the global Problem-Reaction-Solution that was World War Two. All these changes were significant. Israel would become the headquarters of the Sabbatians and the revolution in China would prepare the ground and control system for the events of 2019/2020.

Renegade Minds know there are no borders except for public consumption. The Cult is a seamless, borderless global entity and to understand the game we need to put aside labels like borders, nations, countries, communism, fascism and democracy. These delude the population into believing that countries are ruled within their borders by a government of whatever shade when these are mere agencies of a global power. America's illusion of democracy and China's communism/fascism are subsidiaries – vehicles – for the same agenda. We may hear about conflict and competition between America and China and on the lower levels that will be true; but at the Cult level they are branches of the same company in the way of the McDonald's example I gave earlier. I have tracked in the books over the years support by US governments of both parties for Chinese Communist Party infiltration of American society through allowing the sale of land, even military facilities, and the acquisition of American business and university influence. All this is underpinned by the infamous stealing of intellectual property and technological know-how. Cult-owned Silicon Valley corporations waive their fraudulent 'morality' to do business with human-rights-free China; Cult-controlled Disney has become China's PR department; and China in effect owns 'American' sports such as basketball which depends for much of its income on Chinese audiences. As a result any sports player, coach or official speaking out against China's horrific human rights record is immediately condemned or fired by the China-worshipping National Basketball Association. One of the first acts of China-controlled Biden was to issue an executive order telling federal agencies to stop making references to the 'virus' by the 'geographic location of its origin'. Long-time Congressman Jerry Nadler warned that criticising China, America's biggest rival, leads to hate crimes against Asian people in the United States. So shut up you bigot. China is fast closing in on Israel as a country that must not be criticised which is apt, really, given that Sabbatians control them both. The two countries have developed close economic, military, technological and strategic ties which include involvement in China's 'Silk Road' transport and economic initiative to connect China with Europe. Israel was the first country in the Middle East to recognise the establishment of Mao's tyranny in 1950 months after it was established.

Project Wuhan – the 'Covid' Psyop

I emphasise again that the Cult plays the long game and what is happening to the world today is the result of centuries of calculated manipulation following a script to take control step-by-step of every aspect of human society. I will discuss later the common force behind all this that has spanned those centuries and thousands of years if the truth be told. Instigating the Mao revolution in China in 1949 with a 2020 'pandemic' in mind is not only how they work – the 71 years between them is really quite short by the Cult's standards of manipulation preparation. The reason for the Cult's Chinese revolution was to create a fiercely-controlled environment within which an extreme structure for human control could be incubated to eventually be unleashed across the world. We have seen this happen since the 'pandemic' emerged from China with the Chinese control-structure founded on AI technology and tyrannical enforcement sweep across the West. Until the moment when the Cult went for broke in the West and put its fascism on public display Western governments had to pay some lip-service to freedom and democracy to not alert too many people to the tyranny-in-the-making. Freedoms were more subtly eroded and power centralised with covert government structures put in place waiting for the arrival of 2020 when that smokescreen of 'freedom' could be dispensed with. The West was not able to move towards tyranny before 2020 anything like as fast as China which was created as a tyranny and had no limits on how fast it could construct the Cult's blueprint for global control. When the time came to impose that structure on the world it was the same Cult-owned Chinese communist/fascist government that provided the excuse – the 'Covid pandemic'. It was absolutely crucial to the Cult plan for the Chinese response to the 'pandemic' –

draconian lockdowns of the entire population – to become the blueprint that Western countries would follow to destroy the livelihoods and freedom of their people. This is why the Cult-owned, Gates-owned, WHO Director-General Tedros said early on:

> The Chinese government is to be congratulated for the extraordinary measures it has taken to contain the outbreak. China is actually setting a new standard for outbreak response and it is not an exaggeration.

Forbes magazine said of China: '… those measures protected untold millions from getting the disease'. The Rockefeller Foundation 'epidemic scenario' document in 2010 said 'prophetically':

> However, a few countries did fare better – China in particular. The Chinese government's quick imposition and enforcement of mandatory quarantine for all citizens, as well as its instant and near-hermetic sealing off of all borders, saved millions of lives, stopping the spread of the virus far earlier than in other countries and enabling a swifter post-pandemic recovery.

Once again – *spooky*.

The first official story was the 'bat theory' or rather the bat diversion. The source of the 'virus outbreak' we were told was a ''wet market' in Wuhan where bats and other animals are bought and eaten in horrifically unhygienic conditions. Then another story emerged through the alternative media that the 'virus' had been released on purpose or by accident from a BSL-4 (biosafety level 4) laboratory in Wuhan not far from the wet market. The lab was reported to create and work with lethal concoctions and bioweapons. Biosafety level 4 is the highest in the World Health Organization system of safety and containment. Renegade Minds are aware of what I call designer manipulation. The ideal for the Cult is for people to buy its prime narrative which in the opening salvoes of the 'pandemic' was the wet market story. It knows, however, that there is now a considerable worldwide alternative media of researchers sceptical of anything governments say and they are often given a version of events in a form they can perceive as credible while misdirecting them from the real truth. In this case let them think that the conspiracy involved is a 'bioweapon virus' released from the Wuhan lab to keep them from the real conspiracy – *there is no 'virus'*. The WHO's current position on the source of the outbreak at the time of writing appears to be: 'We haven't got a clue, mate.' This is a good position to maintain mystery and bewilderment. The inner circle will know where the 'virus' came from – *nowhere*. The bottom line was to ensure the public believed there *was* a 'virus' and it didn't much matter if they thought it was natural or had been released from a lab. The belief that there was a 'deadly virus' was all that was needed to trigger global panic and fear. The population was terrified into handing their power to authority and doing what they were told. They had to or they were 'all gonna die'.

In March, 2020, information began to come my way from real doctors and scientists and my own additional research which had my intuition screaming: 'Yes, that's it! *There is no virus*.' The 'bioweapon' was not the 'virus'; it was the *'vaccine'* already being talked about that would be the bioweapon. My conclusion was further enhanced by happenings in Wuhan. The 'virus' was said to be sweeping the city and news footage circulated of people collapsing in the street (which they've never done in the West with the same 'virus'). The Chinese government was building 'new hospitals' in a matter of ten days to 'cope with demand' such was the virulent nature of the 'virus'. Yet in what seemed like no time the 'new hospitals' closed – even if they even opened – and China declared itself 'virus-free'. It was back to business as usual. This was more propaganda to promote the Chinese draconian lockdowns in the West as the way to 'beat the virus'. Trouble was that we subsequently had lockdown after lockdown, but never business as usual. As the people of the West and most of the rest of the world were caught in an ever-worsening spiral of lockdown, social distancing, masks, isolated old people, families forced apart, and livelihood destruction, it was party-time in Wuhan. Pictures emerged of thousands of people enjoying pool parties and concerts. It made no sense until you realised there never was a 'virus' and the whole thing was a Cult set-up to transform human society out of one its major global strongholds – China.

How is it possible to deceive virtually the entire world population into believing there is a deadly virus when there is not even a 'virus' let alone a deadly one? It's nothing like as difficult as you would think and that's clearly true because it happened.

Postscript: See end of book Postscript for more on the 'Wuhan lab virus release' story which the authorities and media were pushing heavily in the summer of 2021 to divert attention from the truth that the 'Covid virus' is pure invention.

CHAPTER FIVE

There *is no* 'virus'

You can fool some of the people all of the time, and all of the people some of the time, but you cannot fool all of the people all of the time
Abraham Lincoln

The greatest form of mind control is repetition. The more you repeat the same mantra of alleged 'facts' the more will accept them to be true. It becomes an 'everyone knows that, mate'. If you can also censor any other version or alternative to your alleged 'facts' you are pretty much home and cooking.

By the start of 2020 the Cult owned the global mainstream media almost in its entirety to spew out its 'Covid' propaganda and ignore or discredit any other information and view. Cult-owned social media platforms in Cult-owned Silicon Valley were poised and ready to unleash a campaign of ferocious censorship to obliterate all but the official narrative. To complete the circle many demands for censorship by Silicon Valley were led by the mainstream media as 'journalists' became full-out enforcers for the Cult both as propagandists and censors. Part of this has been the influx of young people straight out of university who have become 'journalists' in significant positions. They have no experience and a headful of programmed perceptions from their years at school and university at a time when today's young are the most perceptually-targeted generations in known human history given the insidious impact of technology. They enter the media perceptually prepared and ready to repeat the narratives of the system that programmed them to repeat its narratives. The BBC has a truly pathetic ‘specialist disinformation reporter’ called Marianna Spring who fits this bill perfectly. She is clueless about the world, how it works and what is really going on. Her role is to discredit anyone doing the job that a proper journalist would do and system-serving hacks like Spring wouldn’t dare to do or even see the need to do. They are too busy licking the arse of authority which can never be wrong and, in the case of the BBC propaganda programme, *Panorama*, contacting payments systems such as PayPal to have a donations page taken down for a film company making documentaries questioning vaccines. Even the BBC soap opera *EastEnders* included a disgracefully biased scene in which an inarticulate white working class woman was made to look foolish for questioning the ‘vaccine’ while a well-spoken black man and Asian woman promoted the government narrative. It ticked every BBC box and the fact that the black and minority community was resisting the ‘vaccine’ had nothing to do with the way the scene was written. The BBC has become a disgusting tyrannical propaganda and censorship operation that should be defunded and disbanded and a free media take its place with a brief to stop censorship instead of demanding it. A BBC ‘interview’ with Gates goes something like: ‘Mr Gates, sir, if I can call you sir, would you like to tell our audience why you are such a great man, a wonderful humanitarian philanthropist, and why you should absolutely be allowed as a software salesman to decide health policy for approaching eight billion people? Thank you, sir, please sir.’ Propaganda programming has been incessant and merciless and when all you hear is the same story from the media, repeated by those around you who have only heard the same story, is it any wonder that people on a grand scale believe absolute mendacious garbage to be true? You are about to see, too, why this level of information control is necessary when the official ‘Covid’ narrative is so nonsensical and unsupportable by the evidence.

Structure of Deceit

The pyramid structure through which the ‘Covid’ hoax has been manifested is very simple and has to be to work. As few people as possible have to be involved with full knowledge of what they are doing – and why – or the real story would get out. At the top of the pyramid are the inner core of the Cult which controls Bill Gates who, in turn, controls the World Health Organization through his pivotal funding and his puppet Director-General mouthpiece, Tedros. Before he was appointed Tedros was chair of the Gates-founded Global Fund to ‘fight against AIDS, tuberculosis and malaria’, a board member of the Gates-funded ‘vaccine alliance’ GAVI, and on the board of another Gates-funded organisation. Gates owns him and picked him for a specific reason – Tedros is a crook and worse. ‘Dr’ Tedros (he’s not a medical doctor, the first WHO chief not to be) was a member of the tyrannical Marxist government of Ethiopia for decades with all its human rights abuses. He has faced allegations of corruption and misappropriation of funds and was exposed three times for covering up cholera epidemics while Ethiopia’s health minister. Tedros appointed the mass-murdering genocidal Zimbabwe dictator Robert Mugabe as a WHO goodwill ambassador for public health which, as with Tedros, is like appointing a psychopath to run a peace and love campaign. The move was so ridiculous that he had to drop Mugabe in the face of widespread condemnation. American economist David Steinman, a Nobel peace prize nominee, lodged a complaint with the International Criminal Court in The Hague over alleged genocide by Tedros when he was Ethiopia’s foreign minister. Steinman says Tedros was a ‘crucial decision maker’ who directed the actions of Ethiopia’s security forces from 2013 to 2015 and one of three officials in charge when those security services embarked on the ‘killing’ and ‘torturing’ of Ethiopians. You can see where Tedros is coming from and it’s sobering to think that he has been the vehicle for Gates and the Cult to direct the global response to ‘Covid’. Think about that. A psychopathic Cult dictates to psychopath Gates who dictates to psychopath Tedros who dictates how countries of the world must respond to a ‘Covid virus’ never scientifically shown to exist. At the same time psychopathic Cult-owned Silicon Valley information giants like Google, YouTube, Facebook and Twitter announced very early on that they would give the Cult/Gates/Tedros/WHO version of the narrative free advertising and censor those who challenged their intelligence-insulting, mendacious story.

The next layer in the global 'medical' structure below the Cult, Gates and Tedros are the chief medical officers and science 'advisers' in each of the WHO member countries which means virtually all of them. Medical officers and arbiters of science (they're not) then take the WHO policy and recommended responses and impose them on their country's population while the political 'leaders' say they are deciding policy (they're clearly not) by 'following the science' on the advice of the 'experts' – the same medical officers and science 'advisers' (dictators). In this way with the rarest of exceptions the entire world followed the same policy of lockdown, people distancing, masks and 'vaccines' dictated by the psychopathic Cult, psychopathic Gates and psychopathic Tedros who we are supposed to believe give a damn about the health of the world population they are seeking to enslave. That, amazingly, is all there is to it in terms of crucial decision-making. Medical staff in each country then follow like sheep the dictates of the shepherds at the top of the national medical hierarchies – chief medical officers and science 'advisers' who themselves follow like sheep the shepherds of the World Health Organization and the Cult. Shepherds at the national level often have major funding and other connections to Gates and his Bill and Melinda Gates Foundation which carefully hands out money like confetti at a wedding to control the entire global medical system from the WHO down.

Follow the money

Christopher Whitty, Chief Medical Adviser to the UK Government at the centre of 'virus' policy, a senior adviser to the government's Scientific Advisory Group for Emergencies (SAGE), and Executive Board member of the World Health Organization, was gifted a grant of $40 million by the Bill and Melinda Gates Foundation for malaria research in Africa. The BBC described the unelected Whitty as 'the official who will probably have the greatest impact on our everyday lives of any individual policymaker in modern times' and so it turned out. What Gates and Tedros have said Whitty has done like his equivalents around the world. Patrick Vallance, co-chair of SAGE and the government's Chief Scientific Adviser, is a former executive of Big Pharma giant GlaxoSmithKline with its fundamental financial and business connections to Bill Gates. In September, 2020, it was revealed that Vallance owned a deferred bonus of shares in GlaxoSmithKline worth £600,000 while the company was 'developing' a 'Covid vaccine'. Move along now – nothing to see here – what could possibly be wrong with that? Imperial College in London, a major player in 'Covid' policy in Britain and elsewhere with its 'Covid-19' Response Team, is funded by Gates and has big connections to China while the now infamous Professor Neil Ferguson, the useless 'computer modeller' at Imperial College is also funded by Gates. Ferguson delivered the dramatically inaccurate excuse for the first lockdowns (much more in the next chapter). The Institute for Health Metrics and Evaluation (IHME) in the United States, another source of outrageously false 'Covid' computer models to justify lockdowns, is bankrolled by Gates who is a vehement promotor of lockdowns. America's version of Whitty and Vallance, the again now infamous Anthony Fauci, has connections to 'Covid vaccine' maker Moderna as does Bill Gates through funding from the Bill and Melinda Gates Foundation. Fauci is director of the National Institute of Allergy and Infectious Diseases (NIAID), a major recipient of Gates money, and they are very close. Deborah Birx who was appointed White House Coronavirus Response Coordinator in February, 2020, is yet another with ties to Gates. Everywhere you look at the different elements around the world behind the coordination and decision making of the 'Covid' hoax there is Bill Gates and his money. They include the World Health Organization; Centers for Disease Control (CDC) in the United States; National Institutes of Health (NIH) of Anthony Fauci; Imperial College and Neil Ferguson; the London School of Hygiene where Chris Whitty worked; Regulatory agencies like the UK Medicines & Healthcare products Regulatory Agency (MHRA) which gave emergency approval for ‘Covid vaccines’; Wellcome Trust; GAVI, the Vaccine Alliance; the Coalition for Epidemic Preparedness Innovations (CEPI); Johns Hopkins University which has compiled the false ‘Covid’ figures; and the World Economic Forum. A Nationalfile.com article said:

> Gates has a lot of pull in the medical world, he has a multi-million dollar relationship with Dr. Fauci, and Fauci originally took the Gates line supporting vaccines and casting doubt on [the drug hydroxychloroquine]. Coronavirus response team member Dr. Deborah Birx, appointed by former president Obama to serve as United States Global AIDS Coordinator, also sits on the board of a group that has received billions from Gates’ foundation, and Birx reportedly used a disputed Bill Gates-funded model for the White House’s Coronavirus effort. Gates is a big proponent for a population lockdown scenario for the Coronavirus outbreak.

Another funder of Moderna is the Defense Advanced Research Projects Agency (DARPA), the technology-development arm of the Pentagon and one of the most sinister organisations on earth. DARPA had a major role with the CIA covert technology-funding operation In-Q-Tel in the development of Google and social media which is now at the centre of global censorship. Fauci and Gates are extremely close and openly admit to talking regularly about ‘Covid’ policy, but then why wouldn’t Gates have a seat at every national ‘Covid’ table after his Foundation committed $1.75 billion to the ‘fight against Covid-19’. When passed through our Orwellian Translation Unit this means that he has bought and paid for the Cult-driven ‘Covid’ response worldwide. Research the major ‘Covid’ response personnel in your own country and you will find the same Gates funding and other connections again and again. Medical and science chiefs following World Health Organization ‘policy’ sit atop a medical hierarchy in their country of administrators, doctors and nursing staff. These ‘subordinates’ are told they must work and behave in accordance with the policy delivered from the ‘top’ of the national ‘health’ pyramid which is largely the policy delivered by the WHO which is the policy delivered by Gates and the Cult. The whole ‘Covid’ narrative has been imposed on medical staff by a climate of fear although great numbers don’t even need that to comply. They do so through breathtaking levels of ignorance and include doctors who go through life simply repeating what Big Pharma and their hierarchical masters tell them to say and believe. No wonder Big Pharma 'medicine' is one of the biggest killers on Planet Earth.

The same top-down system of intimidation operates with regard to the Cult Big Pharma cartel which also dictates policy through national and global medical systems in this way. The Cult and Big Pharma agendas are the same because the former controls and owns the latter. 'Health' administrators, doctors, and nursing staff are told to support and parrot the dictated policy or they will face consequences which can include being fired. How sad it's been to see medical staff meekly repeating and imposing Cult policy without question and most of those who can see through the deceit are only willing to speak anonymously off the record. They know what will happen if their identity is known. This has left the courageous few to expose the lies about the 'virus', face masks, overwhelmed hospitals that aren't, and the dangers of the 'vaccine' that isn't a vaccine. When these medical professionals and scientists, some renowned in their field, have taken to the Internet to expose the truth their articles, comments and videos have been deleted by Cult-owned Facebook, Twitter and YouTube. What a real head-shaker to see YouTube videos with leading world scientists and highly qualified medical specialists with an added link underneath to the notorious Cult propaganda website *Wikipedia* to find the 'facts' about the same subject.

HIV – the 'Covid' trial-run

I'll give you an example of the consequences for health and truth that come from censorship and unquestioning belief in official narratives. The story was told by PCR inventor Kary Mullis in his book *Dancing Naked in the Mind Field*. He said that in 1984 he accepted as just another scientific fact that Luc Montagnier of France's Pasteur Institute and Robert Gallo of America's National Institutes of Health had independently discovered that a 'retrovirus' dubbed HIV (human immunodeficiency virus) caused AIDS. They were, after all, Mullis writes, specialists in retroviruses. This is how the medical and science pyramids work. Something is announced or *assumed* and then becomes an everybody-knows-that purely through repetition of the assumption as if it is fact. Complete crap becomes accepted truth with no supporting evidence and only repetition of the crap. This is how a 'virus' that doesn't exist became the 'virus' that changed the world. The HIV-AIDS fairy story became a multi-billion pound industry and the media poured out propaganda terrifying the world about the deadly HIV 'virus' that caused the lethal AIDS. By then Mullis was working at a lab in Santa Monica, California, to detect retroviruses with his PCR test in blood donations received by the Red Cross. In doing so he asked a virologist where he could find a reference for HIV being the cause of AIDS. 'You don't need a reference,' the virologist said … *'Everybody knows it.'* Mullis said he wanted to quote a reference in the report he was doing and he said he felt a little funny about not knowing the source of such an important discovery when everyone else seemed to. The virologist suggested he cite a report by the Centers for Disease Control and Prevention (CDC) on morbidity and mortality. Mullis read the report, but it only said that an organism had been identified and did not say how. The report did not identify the original scientific work. Physicians, however, *assumed* (key recurring theme) that if the CDC was convinced that HIV caused AIDS then proof must exist. Mullis continues:

> I did computer searches. Neither Montagnier, Gallo, nor anyone else had published papers describing experiments which led to the conclusion that HIV probably caused AIDS. I read the papers in Science for which they had become well known as AIDS doctors, but all they had said there was that they had found evidence of a past infection by something which was probably HIV in some AIDS patients.
>
> They found antibodies. Antibodies to viruses had always been considered evidence of past disease, not present disease. Antibodies signaled that the virus had been defeated. The patient had saved himself. There was no indication in these papers that this virus caused a disease. They didn't show that everybody with the antibodies had the disease. In fact they found some healthy people with antibodies.

Mullis asked why their work had been published if Montagnier and Gallo hadn't really found this evidence, and why had they been fighting so hard to get credit for the discovery? He says he was hesitant to write 'HIV is the probable cause of AIDS' until he found published evidence to support that. 'Tens of thousands of scientists and researchers were spending billions of dollars a year doing research based on this idea,' Mullis writes. 'The reason had to be there somewhere; otherwise these people would not have allowed their research to settle into one narrow channel of investigation.' He said he lectured about PCR at numerous meetings where people were always talking about HIV and he asked them how they knew that HIV was the cause of AIDS:

> Everyone said something. Everyone had the answer at home, in the office, in some drawer. They all knew, and they would send me the papers as soon as they got back. But I never got any papers. Nobody ever sent me the news about how AIDS was caused by HIV.

Eventually Mullis was able to ask Montagnier himself about the reference proof when he lectured in San Diego at the grand opening of the University of California AIDS Research Center. Mullis says this was the last time he would ask his question without showing anger. Montagnier said he should reference the CDC report. 'I read it', Mullis said, and it didn't answer the question. 'If Montagnier didn't know the answer who the hell did?' Then one night Mullis was driving when an interview came on National Public Radio with Peter Duesberg, a prominent virologist at Berkeley and a California Scientist of the Year. Mullis says he finally understood why he could not find references that connected HIV to AIDS – *there weren't any!* No one had ever proved that HIV causes AIDS even though it had spawned a multi-billion pound global industry and the media was repeating this as fact every day in their articles and broadcasts terrifying the shit out of people about AIDS and giving the impression that a positive test for HIV (see 'Covid') was a death sentence. Duesberg was a threat to the AIDS gravy train and the agenda that underpinned it. He was therefore abused and castigated after he told the Proceedings of the National Academy of Sciences there was no good evidence implicating the new ‘virus’. Editors rejected his manuscripts and his research funds were deleted. Mullis points out that the CDC has defined AIDS as one of more than 30 diseases *if accompanied* by a positive result on a test that detects antibodies to HIV; but those same diseases are not defined as AIDS cases when antibodies are not detected:

> If an HIV-positive woman develops uterine cancer, for example, she is considered to have AIDS. If she is not HIV positive, she simply has uterine cancer. An HIV-positive man with tuberculosis has AIDS; if he tests negative he simply has tuberculosis. If he lives in Kenya or Colombia, where the test for HIV antibodies is too expensive, he is simply presumed to have the antibodies and therefore AIDS, and therefore he can be treated in the World Health Organization’s clinic. It’s the only medical help available in some places. And it’s free, because the countries that support WHO are worried about AIDS.

Mullis accuses the CDC of continually adding new diseases (see ever more ‘Covid symptoms’) to the grand AIDS definition and of virtually doctoring the books to make it appear as if the disease continued to spread. He cites how in 1993 the CDC enormously broadened its AIDS definition and county health authorities were delighted because they received $2,500 per year from the Federal government for every reported AIDS case. Ladies and gentlemen, I have just described, via Kary Mullis, the ‘Covid pandemic’ of 2020 and beyond. Every element is the same and it’s been pulled off in the same way by the same networks.

The ‘Covid virus’ exists? Okay – prove it. Er … still waiting

What Kary Mullis described with regard to ‘HIV’ has been repeated with ‘Covid’. A claim is made that a new, or ‘novel’, infection has been found and the entire medical system of the world repeats that as fact exactly as they did with HIV and AIDS. No one in the mainstream asks rather relevant questions such as ‘How do you know?’ and ‘Where is your proof?’ The SARS-Cov-2 ‘virus’ and the ‘Covid-19 disease’ became an overnight ‘everybody-knows-that’. The origin could be debated and mulled over, but what you could not suggest was that ‘SARS-Cov-2’ didn’t exist. That would be ridiculous. ‘Everybody knows’ the ‘virus’ exists. Well, I didn’t for one along with American proper doctors like Andrew Kaufman and Tom Cowan and long-time American proper journalist Jon Rappaport. We dared to pursue the obvious and simple question: ‘Where’s the evidence?’ The overwhelming majority in medicine, journalism and the general public did not think to ask that. After all, *everyone knew* there was a new ‘virus’. Everyone was saying so and I heard it on the BBC. Some would eventually argue that the ‘deadly virus’ was nothing like as deadly as claimed, but few would venture into the realms of its very existence. Had they done so they would have found that the evidence for that claim had gone AWOL as with HIV causes AIDS. In fact, not even that. For something to go AWOL it has to exist in the first place and scientific proof for a ‘SARS-Cov-2’ can be filed under nothing, nowhere and zilch.

Dr Andrew Kaufman is a board-certified forensic psychiatrist in New York State, a Doctor of Medicine and former Assistant Professor and Medical Director of Psychiatry at SUNY Upstate Medical University, and Medical Instructor of Hematology and Oncology at the Medical School of South Carolina. He also studied biology at the Massachusetts Institute of Technology (MIT) and trained in Psychiatry at Duke University. Kaufman is retired from allopathic medicine, but remains a consultant and educator on natural healing, I saw a video of his very early on in the ‘Covid’ hoax in which he questioned claims about the ‘virus’ in the absence of any supporting evidence and with plenty pointing the other way. I did everything I could to circulate his work which I felt was asking the pivotal questions that needed an answer. I can recommend an excellent pull-together interview he did with the website The Last Vagabond entitled *Dr Andrew Kaufman: Virus Isolation, Terrain Theory and Covid-19* and his website is andrewkaufmanmd.com. Kaufman is not only a forensic psychiatrist; he is forensic in all that he does. He always reads original scientific papers, experiments and studies instead of second-third-fourth-hand reports about the ‘virus’ in the media which are repeating the repeated repetition of the narrative. When he did so with the original Chinese ‘virus’ papers Kaufman realised that there was no evidence of a ‘SARS-Cov-2’. They had never – from the start – shown it to exist and every repeat of this claim worldwide was based on the accepted existence of proof that was nowhere to be found – see Kary Mullis and HIV. Here we go again.

Let’s postulate

Kaufman discovered that the Chinese authorities immediately concluded that the cause of an illness that broke out among about 200 initial patients in Wuhan was a ‘new virus’ when there were no grounds to make that conclusion. The alleged ‘virus’ was not isolated from other genetic material in their samples and then shown through a system known as Koch’s postulates to be the causative agent of the illness. The world was told that the SARS-Cov-2 ‘virus’ caused a disease they called ‘Covid-19’ which had ‘flu-like’ symptoms and could lead to respiratory problems and pneumonia. If it wasn’t so tragic it would almost be funny. *‘Flu-like’ symptoms’? Pneumonia? Respiratory disease?* What in *CHINA* and particularly in *Wuhan*, one of the most polluted cities in the world with a resulting epidemic of respiratory disease?? Three hundred thousand people get pneumonia in China every year and there are nearly a billion cases worldwide of ‘flu-like symptoms’. These have a whole range of causes – including pollution in Wuhan – but no other possibility was credibly considered in late 2019 when the world was told there was a new and deadly ‘virus’. The global prevalence of pneumonia and ‘flu-like systems’ gave the Cult networks unlimited potential to re-diagnose these other causes as the mythical ‘Covid-19’ and that is what they did from the very start. Kaufman revealed how Chinese medical and science authorities (all subordinates to the Cult-owned communist government) took genetic material from the lungs of only a few of the first patients. The material contained their own cells, bacteria, fungi and other microorganisms living in their bodies. The only way you could prove the existence of the ‘virus’ and its responsibility for the alleged ‘Covid-19’ was to isolate the virus from all the other material – a process also known as ‘purification’ – and then follow the postulates sequence developed in the late 19th century by German physician and bacteriologist Robert Koch which became the 'gold standard' for connecting an alleged causation agent to a disease:

1. The microorganism (bacteria, fungus, virus, etc.) must be present in every case of the disease and all patients must have the same symptoms. It must also *not be present in healthy individuals*.

2. The microorganism must be isolated from the host with the disease. If the microorganism is a bacteria or fungus it must be grown in a pure culture. If it is a virus, it must be purified (i.e. containing no other material except the virus particles) from a clinical sample.

3. The specific disease, with all of its characteristics, must be reproduced when the infectious agent (the purified virus or a pure culture of bacteria or fungi) is inoculated into a healthy, susceptible host.

4. The microorganism must be recoverable from the experimentally infected host as in step 2.

Not one of these criteria has been met in the case of 'SARS-Cov-2' and 'Covid-19'. Not ONE. *EVER*. Robert Koch refers to bacteria and not viruses. What are called 'viral particles' are so minute (hence masks are useless by any definition) that they could only be seen after the invention of the electron microscope in the 1930s and can still only be observed through that means. American bacteriologist and virologist Thomas Milton Rivers, the so-called 'Father of Modern Virology' who was very significantly director of the Rockefeller Institute for Medical Research in the 1930s, developed a less stringent version of Koch's postulates to identify 'virus' causation known as 'Rivers criteria'. 'Covid' did not pass that process either. Some even doubt whether any 'virus' can be isolated from other particles containing genetic material in the Koch method. Freedom of Information requests in many countries asking for scientific proof that the 'Covid virus' has been purified and isolated and shown to exist have all come back with a 'we don't have that' and when this happened with a request to the UK Department of Health they added this comment:

> However, outside of the scope of the [Freedom of Information Act] and on a discretionary basis, the following information has been advised to us, which may be of interest. Most infectious diseases are caused by viruses, bacteria or fungi. Some bacteria or fungi have the capacity to grow on their own in isolation, for example in colonies on a petri dish. Viruses are different in that they are what we call 'obligate pathogens' – that is, they cannot survive or reproduce without infecting a host ...
>
> … For some diseases, it is possible to establish causation between a microorganism and a disease by isolating the pathogen from a patient, growing it in pure culture and reintroducing it to a healthy organism. These are known as 'Koch's postulates' and were developed in 1882. However, as our understanding of disease and different disease-causing agents has advanced, these are no longer the method for determining causation [Andrew Kaufman asks why in that case are there two published articles falsely claiming to satisfy Koch's postulates].
>
> It has long been known that viral diseases cannot be identified in this way as viruses cannot be grown in 'pure culture'. When a patient is tested for a viral illness, this is normally done by looking for the presence of antigens, or viral genetic code in a host with molecular biology techniques [Kaufman asks how you could know the origin of these chemicals without having a pure culture for comparison].
>
> For the record 'antigens' are defined so:
>
> Invading microorganisms have antigens on their surface that the human body can recognise as being foreign – meaning not belonging to it. When the body recognises a foreign antigen, lymphocytes (white blood cells) produce antibodies, which are complementary in shape to the antigen.

Notwithstanding that this is open to question in relation to 'SARS-Cov-2' the presence of 'antibodies' can have many causes and they are found in people that are perfectly well. Kary Mullis said: 'Antibodies … had always been considered evidence of past disease, not present disease.'

'Covid' really is a *computer* 'virus'

Where the UK Department of Health statement says 'viruses' are now 'diagnosed' through a 'viral genetic code in a host with molecular biology techniques', they mean … *the PCR test* which its inventor said cannot test for infectious disease. They have no credible method of connecting a 'virus' to a disease and we will see that there is no scientific proof that any 'virus' causes any disease or there is any such thing as a 'virus' in the way that it is described. Tenacious Canadian researcher Christine Massey and her team made some 40 Freedom of Information requests to national public health agencies in different countries asking for proof that SARS-CoV-2 has been isolated and not one of them could supply that information. Massey said of her request in Canada: 'Freedom of Information reveals Public Health Agency of Canada has no record of 'SARS-COV-2' isolation performed by anyone, anywhere, ever.' If you accept the comment from the UK Department of Health it's because they can't isolate a 'virus'. Even so many 'science' papers claimed to have isolated the 'Covid virus' until they were questioned and had to admit they hadn't. A reply from the Robert Koch Institute in Germany was typical: 'I am not aware of a paper which purified isolated SARS-CoV-2.' So what the hell was Christian Drosten and his gang using to design the 'Covid' testing protocol that has produced all the illusory Covid' cases and 'Covid' deaths when the head of the Chinese version of the CDC admitted there was a problem right from the start in that the 'virus' had never been isolated/purified? Breathe deeply: What they are calling 'Covid' is actually created by a *computer program* i.e. *they made it up* – er, that's it. They took lung fluid, with many sources of genetic material, from one single person alleged to be infected with Covid-19 by a PCR test which they *claimed*, without clear evidence, contained a 'virus'. They used several computer programs to create a model of a theoretical virus genome sequence from more than fifty-six million small sequences of RNA, each of an unknown source, assembling them like a puzzle with no known solution. The computer filled in the gaps with sequences from bits in the gene bank to make it look like a bat SARS-like coronavirus! A wave of the magic wand and poof, an in silico (computer-generated) genome, a scientific fantasy, was created. UK health researcher Dr Kevin Corbett made the same point with this analogy:

> … It's like giving you a few bones and saying that's your fish. It could be any fish. Not even a skeleton. Here's a few fragments of bones. That's your fish … It's all from gene bank and the bits of the virus sequence that weren't there they made up.
>
> They synthetically created them to fill in the blanks. That's what genetics is; it's a code. So it's ABBBCCDDD and you're missing some what you think is EEE so you put it in. It's all

> synthetic. You just manufacture the bits that are missing. This is the end result of the geneticization of virology. This is basically a computer virus.

Further confirmation came in an email exchange between British citizen journalist Frances Leader and the government's Medicines & Healthcare Products Regulatory Agency (the Gates-funded MHRA) which gave emergency permission for untested 'Covid vaccines' to be used. The agency admitted that the 'vaccine' is not based on an isolated 'virus', but comes from a *computer-generated model*. Frances Leader was naturally banned from Cult-owned fascist Twitter for making this exchange public. The process of creating computer-generated alleged 'viruses' is called 'in silico' or 'in silicon' – computer chips – and the term 'in silico' is believed to originate with biological experiments using only a computer in 1989. 'Vaccines' involved with 'Covid' are also produced 'in silico' or by computer not a natural process. If the original 'virus' is nothing more than a made-up computer model how can there be 'new variants' of something that never existed in the first place? They are not new 'variants'; they are new *computer models* only minutely different to the original program and designed to further terrify the population into having the 'vaccine' and submitting to fascism. You want a 'new variant'? Click, click, enter – there you go. Tell the medical profession that you have discovered a 'South African variant', 'UK variants' or a 'Brazilian variant' and in the usual HIV-causes-AIDS manner they will unquestioningly repeat it with no evidence whatsoever to support these claims. They will go on television and warn about the dangers of 'new variants' while doing nothing more than repeating what they have been told to be true and knowing that any deviation from that would be career suicide. Big-time insiders will know it's a hoax, but much of the medical community is clueless about the way they are being played and themselves play the public without even being aware they are doing so. What an interesting 'coincidence' that AstraZeneca and Oxford University were conducting 'Covid vaccine trials' in the three countries – the UK, South Africa and Brazil – where the first three 'variants' were claimed to have 'broken out'.

Here's your 'virus' – it's a unicorn

Dr Andrew Kaufman presented a brilliant analysis describing how the 'virus' was imagined into fake existence when he dissected an article published by *Nature* and written by 19 authors detailing *alleged* 'sequencing of a complete viral genome' of the 'new SARS-CoV-2 virus'. This computer-modelled *in silico* genome was used as a template for all subsequent genome sequencing experiments that resulted in the so-called variants which he said now number more than *6,000*. The fake genome was constructed from more than 56 million individual short strands of RNA. Those little pieces were assembled into longer pieces by finding areas of overlapping sequences. The computer programs created over two million possible combinations from which the authors simply chose the longest one. They then compared this to a 'bat virus' and the computer 'alignment' rearranged the sequence and filled in the gaps! They called this computer-generated abomination the 'complete genome'. Dr Tom Cowan, a fellow medical author and collaborator with Kaufman, said such computer-generation constitutes scientific fraud and he makes this superb analogy:

> Here is an equivalency: A group of researchers claim to have found a unicorn because they found a piece of a hoof, a hair from a tail, and a snippet of a horn. They then add that information into a computer and program it to re-create the unicorn, and they then claim this computer re-creation is the real unicorn. Of course, they had never actually seen a unicorn so could not possibly have examined its genetic makeup to compare their samples with the actual unicorn's hair, hooves and horn.
>
> The researchers claim they decided which is the real genome of SARS-CoV-2 by 'consensus', sort of like a vote. Again, different computer programs will come up with different versions of the imaginary 'unicorn', so they come together as a group and decide which is the real imaginary unicorn.

This is how the 'virus' that has transformed the world was brought into fraudulent 'existence'. Extraordinary, yes, but as the Nazis said the bigger the lie the more will believe it. Cowan, however, wasn't finished and he went on to identify what he called the real blockbuster in the paper. He quotes this section from a paper written by virologists and published by the CDC and then explains what it means:

> Therefore, we examined the capacity of SARS-CoV-2 to infect and replicate in several common primate and human cell lines, including human adenocarcinoma cells (A549), human liver cells (HUH 7.0), and human embryonic kidney cells (HEK-293T). In addition to Vero E6 and Vero CCL81 cells. ... Each cell line was inoculated at high multiplicity of infection and examined 24h post-infection.
>
> No CPE was observed in any of the cell lines except in Vero cells, which grew to greater than 10 to the 7th power at 24 h post-infection. In contrast, HUH 7.0 and 293T showed only modest viral replication, and A549 cells were incompatible with SARS CoV-2 infection.

Cowan explains that when virologists attempt to prove infection they have three possible 'hosts' or models on which they can test. The first was humans. Exposure to humans was generally not done for ethical reasons and has never been done with SARS-CoV-2 or any coronavirus. The second possible host was animals. Cowan said that forgetting for a moment that they never actually use purified virus when exposing animals they do use solutions that they *claim* contain the virus. Exposure to animals has been done with SARS-CoV-2 in an experiment involving mice and this is what they found: *None of the wild (normal) mice got sick*. In a group of genetically-modified mice, a statistically insignificant number lost weight and had slightly bristled fur, but they experienced nothing like the illness called 'Covid-19'. Cowan said the third method – the one they mostly rely on – is to inoculate solutions they *say* contain the virus onto a variety of tissue cultures. This process had never been shown to kill tissue *unless* the sample material was starved of nutrients and poisoned as *part of the process*. Yes, incredibly, in tissue experiments designed to show the 'virus' is responsible for killing the tissue they starve the tissue of nutrients and add toxic drugs including antibiotics and they do not have control studies to see if it's the starvation and poisoning that is degrading the tissue rather than the 'virus' they allege to be in there somewhere. You want me to pinch you? Yep, I understand. Tom Cowan said this about the whole nonsensical farce as he explains what that quote from the CDC paper really means:

> The shocking thing about the above quote is that using their own methods, the virologists found that solutions containing SARS-CoV-2 – even in high amounts – were NOT, I repeat NOT, infective to any of the three human tissue cultures they tested. In plain English, this means they proved, on their terms, that this 'new coronavirus' is not infectious to human beings. It is ONLY infective to monkey kidney cells, and only then when you add two potent drugs (gentamicin and amphotericin), known to be toxic to kidneys, to the mix.
>
> My friends, read this again and again. These virologists, published by the CDC, performed a clear proof, on their terms, showing that the SARS-CoV-2 virus is harmless to human beings. That is the only possible conclusion, but, unfortunately, this result is not even mentioned in their conclusion. They simply say they can provide virus stocks cultured only on monkey Vero cells, thanks for coming.

Cowan concluded: 'If people really understood how this "science" was done, I would hope they would storm the gates and demand honesty, transparency and truth.' Dr Michael Yeadon, former Vice President and Chief Scientific Adviser at drug giant Pfizer has been a vocal critic of the 'Covid vaccine' and its potential for multiple harm. He said in an interview in April, 2021, that 'not one [vaccine] has the virus. He was asked why vaccines normally using a 'dead' version of a disease to activate the immune system were not used for 'Covid' and instead we had the synthetic methods of the 'mRNA Covid vaccine'. Yeadon said that to do the former 'you'd have to have some of [the virus] wouldn't you?' He added: 'No-one's got any – seriously.' Yeadon said that surely they couldn't have fooled the whole world for a year without having a virus, 'but oddly enough ask around – no one's got it'. He didn't know why with all the 'great labs' around the world that the virus had not been isolated – 'Maybe they've been too busy running bad PCR tests and vaccines that people don't need.' What is today called 'science' is not 'science' at all. Science is no longer what is, but whatever people can be manipulated to *believe* that it is. Real science has been hijacked by the Cult to dispense and produce the 'expert scientists' and contentions that suit the agenda of the Cult. How big-time this has happened with the 'Covid' hoax which is entirely based on fake science delivered by fake 'scientists' and fake 'doctors'. The human-caused climate change hoax is also entirely based on fake science delivered by fake 'scientists' and fake 'climate experts'. In both cases real scientists, climate experts and doctors have their views suppressed and deleted by the Cult-owned science establishment, media and Silicon Valley. This is the 'science' that politicians claim to be 'following' and a common denominator of 'Covid' and climate are Cult psychopaths Bill Gates and his mate Klaus Schwab at the Gates-funded World Economic Forum. But, don't worry, it's all just a coincidence and absolutely nothing to worry about. *Zzzzzzzz*.

What is a 'virus' REALLY?

Dr Tom Cowan is one of many contesting the very existence of viruses let alone that they cause disease. This is understandable when there is no scientific evidence for a disease-causing 'virus'. German virologist Dr Stefan Lanka won a landmark case in 2017 in the German Supreme Court over his contention that there is no such thing as a measles virus. He had offered a big prize for anyone who could prove there is and Lanka won his case when someone sought to claim the money. There is currently a prize of more than 225,000 euros on offer from an Isolate Truth Fund for anyone who can prove the isolation of SARS-CoV-2 and its genetic substance. Lanka wrote in an article headed 'The Misconception Called Virus' that scientists think a 'virus' is causing tissue to become diseased and degraded when in fact it is the *processes they are using* which do that – not a 'virus'. Lanka has done an important job in making this point clear as Cowan did in his analysis of the CDC paper. Lanka says that all claims about viruses as disease-causing pathogens are wrong and based on 'easily recognisable, understandable and verifiable misinterpretations.' Scientists believed they were working with 'viruses' in their laboratories when they were really working with 'typical particles of specific dying tissues or cells …' Lanka said that the tissue decaying process claimed to be caused by a 'virus' still happens when no alleged 'virus' is involved. It's the *process* that does the damage and not a 'virus'. The genetic sample is deprived of nutrients, removed from its energy supply through removal from the body and then doused in toxic antibiotics to remove any bacteria. He confirms again that establishment scientists do not (pinch me) conduct control experiments to see if this is the case and if they did they would see the claims that 'viruses' are doing the damage is nonsense. He adds that during the measles 'virus' court case he commissioned an independent laboratory to perform just such a control experiment and the result was that the tissues and cells died in the exact same way as with alleged 'infected' material. This is supported by a gathering number of scientists, doctors and researchers who reject what is called 'germ theory' or the belief in the body being infected by contagious sources emitted by other people. Researchers Dawn Lester and David Parker take the same stance in their highly-detailed and sourced book *What Really Makes You Ill – Why everything you thought you knew about disease is wrong* which was recommended to me by a number of medical professionals genuinely seeking the truth. Lester and Parker say there is no provable scientific evidence to show that a 'virus' can be transmitted between people or people and animals or animals and people:

> The definition also claims that viruses are the cause of many diseases, as if this has been definitively proven. But this is not the case; there is no original scientific evidence that definitively demonstrates that any virus is the cause of any disease. The burden of proof for any theory lies with those who proposed it; but none of the existing documents provides 'proof' that supports the claim that 'viruses' are pathogens.

Dr Tom Cowan employs one of his clever analogies to describe the process by which a 'virus' is named as the culprit for a disease when what is called a 'virus' is only material released by cells detoxing themselves from infiltration by chemical or radiation poisoning. The tidal wave of technologically-generated radiation in the 'smart' modern world plus all the toxic food and drink are causing this to happen more than ever. Deluded 'scientists' misread this as a gathering impact of what they wrongly label 'viruses'.

Paper can infect houses

Cowan said in an article for davidicke.com – with his tongue only mildly in his cheek – that he believed he had made a tremendous discovery that may revolutionise science. He had discovered that small bits of paper are alive, 'well alive-ish', can 'infect' houses, and then reproduce themselves inside the house. The result was that this explosion of growth in the paper inside the house causes the house to explode, blowing it to smithereens. His evidence for this new theory is that in the past months he had carefully examined many of the houses in his neighbourhood and found almost no scraps of paper on the lawns and surrounds of the house. There was an occasional stray label, but nothing more. Then he would return to these same houses a week or so later and with a few, not all of them, particularly the old and decrepit ones, he found to his shock and surprise they were littered with stray bits of paper. He knew then that the paper had infected these houses, made copies of itself, and blew up the house. A young boy on a bicycle at one of the sites told him he had seen a demolition crew using dynamite to explode the house the previous week, but Cowan dismissed this as the idle thoughts of silly boys because 'I was on to something big'. He was on to how 'scientists' mistake genetic material in the detoxifying process for something they call a 'virus'. Cowan said of his house and paper story:

> If this sounds crazy to you, it's because it should. This scenario is obviously nuts. But consider this admittedly embellished, for effect, current viral theory that all scientists, medical doctors and virologists currently believe.

He takes the example of the 'novel SARS-Cov2' virus to prove the point. First they take someone with an undefined illness called 'Covid-19' and don't even attempt to find any virus in their sputum. Never mind the scientists still describe how this 'virus', which they have not located attaches to a cell receptor, injects its genetic material, in 'Covid's' case, RNA, into the cell. The RNA once inserted exploits the cell to reproduce itself and makes 'thousands, nay millions, of copies of itself … Then it emerges victorious to claim its next victim':

If you were to look in the scientific literature for proof, actual scientific proof, that uniform SARS-CoV2 viruses have been properly isolated from the sputum of a sick person, that actual spike proteins could be seen protruding from the virus (which has not been found), you would find that such evidence doesn't exist.

If you go looking in the published scientific literature for actual pictures, proof, that these spike proteins or any viral proteins are ever attached to any receptor embedded in any cell membrane, you would also find that no such evidence exists. If you were to look for a video or documented evidence of the intact virus injecting its genetic material into the body of the cell, reproducing itself and then emerging victorious by budding off the cell membrane, you would find that no such evidence exists.

The closest thing you would find is electron micrograph pictures of cellular particles, possibly attached to cell debris, both of which to be seen were stained by heavy metals, a process that completely distorts their architecture within the living organism. This is like finding bits of paper stuck to the blown-up bricks, thereby proving the paper emerged by taking pieces of the bricks on its way out.

The Enders baloney

Cowan describes the 'Covid' story as being just as make-believe as his paper story and he charts back this fantasy to a Nobel Prize winner called John Enders (1897-1985), an American biomedical scientist who has been dubbed 'The Father of Modern Vaccines'. Enders is claimed to have 'discovered' the process of the viral culture which 'proved' that a 'virus' caused measles. Cowan explains how Enders did this 'by using the EXACT same procedure that has been followed by every virologist to find and characterize every new virus since 1954'. Enders took throat swabs from children with measles and immersed them in 2ml of milk. Penicillin (100u/ml) and the antibiotic streptomycin (50,g/ml) were added and the whole mix was centrifuged – rotated at high speed to separate large cellular debris from small particles and molecules as with milk and cream, for example. Cowan says that if the aim is to find little particles of genetic material ('viruses') in the snot from children with measles it would seem that the last thing you would do is mix the snot with other material – milk –that also has genetic material. 'How are you ever going to know whether whatever you found came from the snot or the milk?' He points out that streptomycin is a 'nephrotoxic' or poisonous-to-the-kidney drug. You will see the relevance of that shortly. Cowan says that it gets worse, much worse, when Enders describes the culture medium upon which the virus ‘grows’: ‘The culture medium consisted of bovine amniotic fluid (90%), beef embryo extract (5%), horse serum (5%), antibiotics and phenol red as an indicator of cell metabolism.’ Cowan asks incredulously: ‘Did he just say that the culture medium also contained fluids and tissues that are themselves rich sources of genetic material?’ The genetic cocktail, or ‘medium’, is inoculated onto tissue and cells from rhesus monkey *kidney* tissue. This is where the importance of streptomycin comes in and currently-used antimicrobials and other drugs that are *poisonous to kidneys* and used in ALL modern viral cultures (e.g. gentamicin, streptomycin, and amphotericin). Cowan asks: ‘How are you ever going to know from this witch’s brew where any genetic material comes from as we now have five different sources of rich genetic material in our mix?’ Remember, he says, that all genetic material, whether from monkey kidney tissues, bovine serum, milk, etc., is made from the exact same components. The same central question returns: ‘How are you possibly going to know that it was the virus that killed the kidney tissue and not the toxic antibiotic and starvation rations on which you are growing the tissue?’ John Enders answered the question himself – *you can’t*:

> A second agent was obtained from an uninoculated culture of monkey kidney cells. The cytopathic changes [death of the cells] it induced in the unstained preparations could not be distinguished with confidence from the viruses isolated from measles.

The death of the cells (‘cytopathic changes’) happened in exactly the same manner, whether they inoculated the kidney tissue with the measles snot or not, Cowan says. ‘This is evidence that the destruction of the tissue, the very proof of viral causation of illness, was not caused by anything in the snot because they saw the same destructive effect when the snot was not even used … the cytopathic, i.e., cell-killing, changes come from the process of the culture itself, not from any virus in any snot, period.’ Enders quotes in his 1957 paper a virologist called Ruckle as reporting similar findings ‘and in addition has isolated an agent from monkey kidney tissue that is so far indistinguishable from human measles virus'. In other words, Cowan says, these particles called 'measles viruses' are simply and clearly breakdown products of the starved and poisoned tissue. For measles 'virus' see all 'viruses' including the so-called 'Covid virus'. Enders, the 'Father of Modern Vaccines', also said:

> There is a potential risk in employing cultures of primate cells for the production of vaccines composed of attenuated virus, since the presence of other agents possibly latent in primate tissues cannot be definitely excluded by any known method.

Cowan further quotes from a paper published in the journal *Viruses* in May, 2020, while the 'Covid pandemic' was well underway in the media if not in reality. 'EVs' here refers to particles of genetic debris from our own tissues, such as exosomes of which more in a moment: 'The remarkable resemblance between EVs and viruses has caused quite a few problems in the studies focused on the analysis of EVs released during viral infections.' Later the paper adds that to date a reliable method that can actually guarantee a complete separation (of EVs from viruses) DOES NOT EXIST. This was published at a time when a fairy tale 'virus' was claimed in total certainty to be causing a fairy tale 'viral disease' called 'Covid-19' – a fairy tale that was already well on the way to transforming human society in the image that the Cult has worked to achieve for so long. Cowan concludes his article:

> To summarize, there is no scientific evidence that pathogenic viruses exist. What we think of as 'viruses' are simply the normal breakdown products of dead and dying tissues and cells. When we are well, we make fewer of these particles; when we are starved, poisoned, suffocated by wearing masks, or afraid, we make more.
>
> There is no engineered virus circulating and making people sick. People in laboratories all over the world are making genetically modified products to make people sick. These are called vaccines. There is no virome, no 'ecosystem' of viruses, viruses are not 8%, 50% or 100 % of our genetic material. These are all simply erroneous ideas based on the misconception called a virus.

What is 'Covid'? Load of bollocks

The background described here by Cowan and Lanka was emphasised in the first video presentation that I saw by Dr Andrew Kaufman when he asked whether the 'Covid virus' was in truth a natural defence mechanism of the body called 'exosomes'. These are released by cells when in states of toxicity – see the same themes returning over and over. They are released ever more profusely as chemical and radiation toxicity increases and think of the potential effect therefore of 5G alone as its destructive frequencies infest the human energetic information field with a gathering pace (5G went online in Wuhan in 2019 as the 'virus' emerged). I'll have more about this later. Exosomes transmit a warning to the rest of the body that 'Houston, we have a problem'. Kaufman presented images of exosomes and compared them with 'Covid' under an electron microscope and the similarity was remarkable. They both attach to the same cell receptors (*claimed* in the case of 'Covid'), contain the same genetic material in the form of RNA or ribonucleic acid, and both are found in 'viral cell cultures' with damaged or dying cells. James Hildreth MD, President and Chief Executive Officer of the Meharry Medical College at Johns Hopkins, said: 'The virus is fully an exosome in every sense of the word.' Kaufman's conclusion was that there is no 'virus': 'This entire pandemic is a completely manufactured crisis … there is no evidence of anyone dying from [this] illness.' Dr Tom Cowan and Sally Fallon Morell, authors of *The Contagion Myth*, published a statement with Dr Kaufman in February, 2021, explaining why the 'virus' does not exist and you can read it that in full in the Appendix.

'Virus' theory can be traced to the 'cell theory' in 1858 of German physician Rudolf Virchow (1821-1920) who contended that disease originates from a single cell infiltrated by a 'virus'. Dr Stefan Lanka said that findings and insights with respect to the structure, function and central importance of tissues in the creation of life, which were already known in 1858, comprehensively refute the cell theory. Virchow ignored them. We have seen the part later played by John Enders in the 1950s and Lanka notes that infection theories were only established as a global dogma through the policies and eugenics of the Third Reich in Nazi Germany (creation of the same Sabbatian cult behind the 'Covid' hoax). Lanka said: 'Before 1933, scientists dared to contradict this theory; after 1933, these critical scientists were silenced'. Dr Tom Cowan's view is that ill-heath is caused by too much of something, too little of something, or toxification from chemicals and radiation – not contagion. We must also highlight as a major source of the 'virus' theology a man still called the 'Father of Modern Virology' – Thomas Milton Rivers (1888-1962). There is no way given the Cult's long game policy that it was a coincidence for the 'Father of Modern Virology' to be director of the Rockefeller Institute for Medical Research from 1937 to 1956 when he is credited with making the Rockefeller Institute a leader in 'viral research'. Cult Rockefellers were the force behind the creation of Big Pharma 'medicine', established the World Health Organisation in 1948, and have long and close associations with the Gates family that now runs the WHO during the pandemic hoax through mega-rich Cult gofer and psychopath Bill Gates.

Only a Renegade Mind can see through all this bullshit by asking the questions that need to be answered, not taking 'no' or prevarication for an answer, and certainly not hiding from the truth in fear of speaking it. Renegade Minds have always changed the world for the better and they will change this one no matter how bleak it may currently appear to be.

CHAPTER SIX

Sequence of deceit

If you tell the truth, you don't have to remember anything
Mark Twain

Against the background that I have laid out this far the sequence that took us from an invented 'virus' in Cult-owned China in late 2019 to the fascist transformation of human society can be seen and understood in a whole new context.

We were told that a deadly disease had broken out in Wuhan and the world media began its campaign (coordinated by behavioural psychologists as we shall see) to terrify the population into unquestioning compliance. We were shown images of Chinese people collapsing in the street which never happened in the West with what was supposed to be the same condition. In the earliest days when alleged cases and deaths were few the fear register was hysterical in many areas of the media and this would expand into the common media narrative across the world. The real story was rather different, but we were never told that. The Chinese government, one of the Cult's biggest centres of global operation, said they had discovered a new illness with flu-like and pneumonia-type symptoms in a city with such toxic air that it is overwhelmed with flu-like symptoms, pneumonia and respiratory disease. Chinese scientists said it was a new – 'novel' – coronavirus which they called Sars-Cov-2 and that it caused a disease they labelled 'Covid-19'. There was no evidence for this and the 'virus' has never to this day been isolated, purified and its genetic code established from that. It was from the beginning a computer-generated fiction. Stories of Chinese whistleblowers saying the number of deaths was being supressed or that the 'new disease' was related to the Wuhan bio-lab misdirected mainstream and alternative media into cul-de-sacs to obscure the real truth – there was no 'virus'.

Chinese scientists took genetic material from the lung fluid of just a few people and said they had found a 'new' disease when this material had a wide range of content. There was no evidence for a 'virus' for the very reasons explained in the last two chapters. The 'virus' has never been shown to (a) exist and (b) cause any disease. People were diagnosed on symptoms that are so widespread in Wuhan and polluted China and with a PCR test that can't detect infectious disease. On this farce the whole global scam was sold to the rest of the world which would also diagnose respiratory disease as 'Covid-19' from symptoms alone or with a PCR test not testing for a 'virus'. Flu miraculously disappeared *worldwide* in 2020 and into 2021 as it was redesignated 'Covid-19'. It was really the same old flu with its 'flu-like' symptoms attributed to 'flu-like' 'Covid-19'. At the same time with very few exceptions the Chinese response of draconian lockdown and fascism was the chosen weapon to respond across the West as recommended by the Cult-owned Tedros at the Cult-owned World Health Organization run by the Cult-owned Gates. All was going according to plan. Chinese scientists – everything in China is controlled by the Cult-owned government – compared their contaminated RNA lung-fluid material with other RNA sequences and said it appeared to be just under 80 percent identical to the SARS-CoV-1 'virus' claimed to be the cause of the SARS (severe acute respiratory syndrome) 'outbreak' in 2003. They decreed that because of this the 'new virus' had to be related and they called it SARS-CoV-2. There are some serious problems with this assumption and *assumption* was all it was. Most 'factual' science turns out to be assumptions repeated into everyone-knows-that. A match of under 80-percent is meaningless. Dr Kaufman makes the point that there's a *96 percent* genetic correlation between humans and chimpanzees, but 'no one would say our genetic material is part of the chimpanzee family’. Yet the Chinese authorities were claiming that a much lower percentage, less than 80 percent, proved the existence of a new ‘coronavirus’. For goodness sake human DNA is 60 percent similar to a *banana*.

You are feeling sleepy

The entire ‘Covid’ hoax is a global Psyop, a psychological operation to program the human mind into believing and fearing a complete fantasy. A crucial aspect of this was what *appeared* to happen in Italy. It was all very well streaming out daily images of an alleged catastrophe in Wuhan, but to the Western mind it was still on the other side of the world in a very different culture and setting. A reaction of ‘this could happen to me and my family’ was still nothing like as intense enough for the mind-doctors. The Cult needed a Western example to push people over that edge and it chose Italy, one of its major global locations going back to the Roman Empire. An Italian ‘Covid’ crisis was manufactured in a particular area called Lombardy which just happens to be notorious for its toxic air and therefore respiratory disease. Wuhan, China, déjà vu. An hysterical media told horror stories of Italians dying from ‘Covid’ in their droves and how Lombardy hospitals were being overrun by a tidal wave of desperately ill people needing treatment after being struck down by the ‘deadly virus’. Here was the psychological turning point the Cult had planned. Wow, if this is happening in Italy, the Western mind concluded, this indeed could happen to me and my family. Another point is that Italian authorities responded by following the Chinese blueprint so vehemently recommended by the Cult-owned World Health Organization. They imposed fascistic lockdowns on the whole country viciously policed with the help of surveillance drones sweeping through the streets seeking out anyone who escaped from mass house arrest. Livelihoods were destroyed and psychology unravelled in the way we have witnessed since in all lockdown countries. Crucial to the plan was that Italy responded in this way to set the precedent of suspending freedom and imposing fascism in a ‘Western liberal democracy’. I emphasised in an animated video explanation on davidicke.com posted in the summer of 2020 how important it was to the Cult to expand the Chinese lockdown model across the West. Without this, and the bare-faced lie that non-symptomatic people could still transmit a ‘disease’ they didn’t have, there was no way locking down the whole population, sick and not sick, could be pulled off. At just the right time and with no evidence Cult operatives and gofers claimed that people without symptoms could pass on the ‘disease’. In the name of protecting the ‘vulnerable’ like elderly people, who lockdowns would kill by the tens of thousands, we had for the first time healthy people told to isolate as well as the sick. The great majority of people who tested positive had no symptoms because there was nothing wrong with them. It was just a trick made possible by a test not testing for the ‘virus’.

Months after my animated video the Gates-funded Professor Neil Ferguson at the Gates-funded Imperial College confirmed that I was right. He didn’t say it in those terms, naturally, but he did say it. Ferguson will enter the story shortly for his outrageously crazy ‘computer models’ that led to Britain, the United States and many other countries following the Chinese and now Italian methods of response. Put another way, following the Cult script. Ferguson said that SAGE, the UK government’s scientific advisory group which has controlled ‘Covid’ policy from the start, wanted to follow the Chinese lockdown model (while they all continued to work and be paid), but they wondered if they could possibly, in Ferguson’s words, ‘get away with it in Europe’. ‘Get away with it’? Who the hell do these moronic, arrogant people think they are? This appalling man Ferguson said that once Italy went into national lockdown they realised they, too, could mimic China:

> It’s a communist one-party state, we said. We couldn’t get away with it in Europe, we thought … and then Italy did it. And we realised we could. Behind this garbage from Ferguson is a simple fact: Doing the same as China in every country was the plan from the start and Ferguson’s ‘models’ would play a central role in achieving that. It’s just a coincidence, of course, and absolutely nothing to worry your little head about.

Oops, sorry, our mistake

Once the Italian segment of the Psyop had done the job it was designed to do a very different story emerged. Italian authorities revealed that 99 percent of those who had 'died from Covid-19' in Italy had one, two, three, or more 'co-morbidities' or illnesses and health problems that could have ended their life. The US Centers for Disease Control and Prevention (CDC) published a figure of 94 percent for Americans dying of 'Covid' while having other serious medical conditions – on average two to three (some five or six) other potential causes of death. In terms of death from an unproven 'virus' I say it is 100 percent. The other one percent in Italy and six percent in the US would presumably have died from 'Covid's' flu-like symptoms with a range of other possible causes in conjunction with a test not testing for the 'virus'. Fox News reported that even more startling figures had emerged in one US county in which 410 of 422 deaths attributed to 'Covid-19' had other potentially deadly health conditions. The Italian National Health Institute said later that the average age of people dying with a 'Covid-19' diagnosis in Italy was about 81. Ninety percent were over 70 with ten percent over 90. In terms of other reasons to die some 80 percent had two or more chronic diseases with half having three or more including cardiovascular problems, diabetes, respiratory problems and cancer. Why is the phantom 'Covid-19' said to kill overwhelmingly old people and hardly affect the young? Old people continually die of many causes and especially respiratory disease which you can re-diagnose 'Covid-19' while young people die in tiny numbers by comparison and rarely of respiratory disease. Old people 'die of Covid' because they die of other things that can be redesignated 'Covid' and it really is that simple.

Flu has flown

The blueprint was in place. Get your illusory 'cases' from a test not testing for the 'virus' and redesignate other causes of death as 'Covid-19'. You have an instant 'pandemic' from something that is nothing more than a computer-generated fiction. With near-on a billion people having ‘flu-like’ symptoms every year the potential was limitless and we can see why flu quickly and apparently miraculously disappeared *worldwide* by being diagnosed ‘Covid-19’. The painfully bloody obvious was explained away by the childlike media in headlines like this in the UK ‘*Independent*’: ‘Not a single case of flu detected by Public Health England this year as Covid restrictions suppress virus’. I kid you not. The masking, social distancing and house arrest that did not make the ‘Covid virus’ disappear somehow did so with the ‘flu virus’. Even worse the article, by a bloke called Samuel Lovett, suggested that maybe the masking, sanitising and other ‘Covid’ measures should continue to keep the flu away. With a ridiculousness that disturbs your breathing (it’s ‘Covid-19’) the said Lovett wrote: ‘With widespread social distancing and mask-wearing measures in place throughout the UK, the usual routes of transmission for influenza have been blocked.’ He had absolutely no evidence to support that statement, but look at the consequences of him acknowledging the obvious. With flu not disappearing at all and only being relabelled ‘Covid-19’ he would have to contemplate that ‘Covid’ was a hoax on a scale that is hard to imagine. You need guts and commitment to truth to even go there and that’s clearly something Samuel Lovett does not have in abundance. He would never have got it through the editors anyway.

Tens of thousands die in the United States alone every winter from flu including many with pneumonia complications. CDC figures record *45 million* Americans diagnosed with flu in 2017-2018 of which 61,000 died and some reports claim 80,000. Where was the same hysteria then that we have seen with ‘Covid-19’? Some 250,000 Americans are admitted to hospital with pneumonia every year with about 50,000 cases proving fatal. About 65 million suffer respiratory disease every year and three million deaths makes this the third biggest cause of death worldwide. You only have to redesignate a portion of all these people ‘Covid-19’ and you have an instant global pandemic or the *appearance* of one. Why would doctors do this? They are told to do this and all but a few dare not refuse those who must be obeyed. Doctors in general are not researching their own knowledge and instead take it direct and unquestioned from the authorities that own them and their careers. The authorities say they must now diagnose these symptoms 'Covid-19' and not flu, or whatever, and they do it. Dark suits say put 'Covid-19' on death certificates no matter what the cause of death and the doctors do it. Renegade Minds don't fall for the illusion that doctors and medical staff are all highly-intelligent, highly-principled, seekers of medical truth. *Some are*, but not the majority. They are repeaters, gofers, and yes sir, no sir, purveyors of what the system demands they purvey. The 'Covid' con is not merely confined to diseases of the lungs. Instructions to doctors to put 'Covid-19' on death certificates for anyone dying of *anything* within 28 days (or much more) of a positive test not testing for the 'virus' opened the floodgates. The term dying *with* 'Covid' and not *of* 'Covid' was coined to cover the truth. Whether it was a *with* or an *of* they were all added to the death numbers attributed to the 'deadly virus' compiled by national governments and globally by the Gates-funded Johns Hopkins operation in the United States that was so involved in those 'pandemic' simulations. Fraudulent deaths were added to the ever-growing list of fraudulent 'cases' from false positives from a false test. No wonder Professor Walter Ricciardi, scientific advisor to the Italian minister of health, said after the Lombardy hysteria had done its job that 'Covid' death rates were due to Italy having the second oldest population in the world and to *how hospitals record deaths*:

> The way in which we code deaths in our country is very generous in the sense that all the people who die in hospitals with the coronavirus are deemed to be dying of the coronavirus. On re-evaluation by the National Institute of Health, only 12 per cent of death certificates have shown a direct causality from coronavirus, while 88 per cent of patients who have died have at least one pre-morbidity – many had two or three.

This is extraordinary enough when you consider the propaganda campaign to use Italy to terrify the world, but how can they even say twelve percent were genuine when the 'virus' has not been shown to exist, its 'code' is a computer program, and diagnosis comes from a test not testing for it? As in China, and soon the world, 'Covid-19' in

Italy was a redesignation of diagnosis. Lies and corruption were to become the real 'pandemic' fuelled by a pathetically-compliant medical system taking its orders from the tiny few at the top of their national hierarchy who answered to the World Health Organization which answers to Gates and the Cult. Doctors were told – ordered – to diagnose a particular set of symptoms 'Covid-19' and put that on the death certificate for any cause of death if the patient had tested positive with a test not testing for the virus or had 'Covid' symptoms like the flu. The United States even introduced big financial incentives to manipulate the figures with hospitals receiving £4,600 from the Medicare system for diagnosing someone with regular pneumonia, $13,000 if they made the diagnosis from the same symptoms 'Covid-19' pneumonia, and $39, 000 if they put a 'Covid' diagnosed patient on a ventilator that would almost certainly kill them. A few – painfully and pathetically few – medical whistleblowers revealed (before Cult-owned YouTube deleted their videos) that they had been instructed to 'let the patient crash' and put them straight on a ventilator instead of going through a series of far less intrusive and dangerous methods as they would have done before the pandemic hoax began and the financial incentives kicked in. We are talking cold-blooded murder given that ventilators are so damaging to respiratory systems they are usually the last step before heaven awaits. Renegade Minds never fall for the belief that people in white coats are all angels of mercy and cannot be full-on psychopaths. I have explained in detail in *The Answer* how what I am describing here played out across the world coordinated by the World Health Organization through the medical hierarchies in almost every country.

Medical scientist calls it

Information about the non-existence of the 'virus' began to emerge for me in late March, 2020, and mushroomed after that. I was sent an email by Sir Julian Rose, a writer, researcher, and organic farming promotor, from a medical scientist friend of his in the United States. Even at that early stage in March the scientist was able to explain how the ‘Covid’ hoax was being manipulated. He said there were no reliable tests for a specific ‘Covid-19 virus’ and nor were there any reliable agencies or media outlets for reporting numbers of actual ‘Covid-19’ cases. We have seen in the long period since then that he was absolutely right. ‘Every action and reaction to Covid-19 is based on totally flawed data and we simply cannot make accurate assessments,’ he said. Most people diagnosed with ‘Covid-19’ were showing nothing more than cold and flu-like symptoms ‘because most coronavirus strains *are* nothing more than cold/flu-like symptoms’. We had farcical situations like an 84-year-old German man testing positive for ‘Covid-19’ and his nursing home ordered to quarantine only for him to be found to have a common cold. The scientist described back then why PCR tests and what he called the ‘Mickey Mouse test kits’ were useless for what they were claimed to be identifying. ‘The idea these kits can isolate a specific virus like Covid-19 is nonsense,’ he said. Significantly, he pointed out that ‘if you want to create a totally false panic about a totally false pandemic – pick a coronavirus’. This is exactly what the Cult-owned Gates, World Economic Forum and Johns Hopkins University did with their Event 201 ‘simulation’ followed by their real-life simulation called the ‘pandemic’. The scientist said that all you had to do was select the sickest of people with respiratory-type diseases in a single location – ‘say Wuhan’ – and administer PCR tests to them. You can then claim that anyone showing ‘viral sequences’ similar to a coronavirus ‘which will inevitably be quite a few’ is suffering from a ‘new’ disease:

> Since you already selected the sickest flu cases a fairly high proportion of your sample will go on to die. You can then say this ‘new’ virus has a CFR [case fatality rate] higher than the flu and use this to infuse more concern and do more tests which will of course produce more ‘cases’, which expands the testing, which produces yet more ‘cases’ and so on and so on. Before long you have your ‘pandemic’, and all you have done is use a simple test kit trick to convert the worst flu and pneumonia cases into something new that doesn’t ACTUALLY EXIST [my emphasis].

He said that you then ‘just run the same scam in other countries’ and make sure to keep the fear message running high ‘so that people will feel panicky and less able to think critically'. The only problem to overcome was the fact *there is no* actual new deadly pathogen and only regular sick people. This meant that deaths from the 'new deadly pathogen' were going to be way too low for a real new deadly virus pandemic, but he said this could be overcome in the following ways – all of which would go on to happen:

> 1. You can claim this is just the beginning and more deaths are imminent [you underpin this with fantasy 'computer projections']. Use this as an excuse to quarantine everyone and then claim the quarantine prevented the expected millions of dead.
>
> 2. You can [say that people] 'minimizing' the dangers are irresponsible and bully them into not talking about numbers.
>
> 3. You can talk crap about made up numbers hoping to blind people with pseudoscience.
>
> 4. You can start testing well people (who, of course, will also likely have shreds of coronavirus [RNA] in them) and thus inflate your 'case figures' with 'asymptomatic carriers' (you will of course have to spin that to sound deadly even though any virologist knows the more symptom-less cases you have the less deadly is your pathogen).

The scientist said that if you take these simple steps 'you can have your own entirely manufactured pandemic up and running in weeks'. His analysis made so early in the hoax was brilliantly prophetic of what would actually unfold. Pulling all the information together in these recent chapters we have this is simple 1, 2, 3, of how you can delude virtually the entire human population into believing in a 'virus' that doesn't exist:

- A 'Covid case' is someone who tests positive with a test not testing for the 'virus'.
- A 'Covid death' is someone who dies of *any cause* within 28 days (or much longer) of testing positive with a test not testing for the 'virus.
- Asymptomatic means there is nothing wrong with you, but they claim you can pass on what you don't have to justify locking

down (quarantining) healthy people in totality.

The foundations of the hoax are that simple. A study involving ten million people in Wuhan, published in November, 2020, demolished the whole lie about those without symptoms passing on the 'virus'. They found '300 asymptomatic cases' and traced their contacts to find that not one of them was detected with the 'virus'. 'Asymptomatic' patients and their contacts were isolated for no less than two weeks and nothing changed. I know it's all crap, but if you are going to claim that those without symptoms can transmit 'the virus' then you must produce evidence for that and they never have. Even World Health Organization official Dr Maria Van Kerkhove, head of the emerging diseases and zoonosis unit, said as early as June, 2020, that she doubted the validity of asymptomatic transmission. She said that 'from the data we have, it still seems to be rare that an asymptomatic person actually transmits onward to a secondary individual' and by 'rare' she meant that she couldn't cite any case of asymptomatic transmission.

The Ferguson factor

The problem for the Cult as it headed into March, 2020, when the script had lockdown due to start, was that despite all the manipulation of the case and death figures they still did not have enough people alleged to have died from 'Covid' to justify mass house arrest. This was overcome in the way the scientist described: 'You can claim this is just the beginning and more deaths are imminent … Use this as an excuse to quarantine everyone and then claim the quarantine prevented the expected millions of dead.' Enter one Professor Neil Ferguson, the Gates-funded 'epidemiologist' at the Gates-funded Imperial College in London. Ferguson is Britain's Christian Drosten in that he has a dire record of predicting health outcomes, but is still called upon to advise government on the next health outcome when another 'crisis' comes along. This may seem to be a strange and ridiculous thing to do. Why would you keep turning for policy guidance to people who have a history of being monumentally wrong? Ah, but it makes sense from the Cult point of view. These ‘experts’ keep on producing predictions that suit the Cult agenda for societal transformation and so it was with Neil Ferguson as he revealed his horrific (and clearly insane) computer model predictions that allowed lockdowns to be imposed in Britain, the United States and many other countries. Ferguson does not have even an A-level in biology and would appear to have no formal training in computer modelling, medicine or epidemiology, according to Derek Winton, an MSc in Computational Intelligence. He wrote an article somewhat aghast at what Ferguson did which included taking no account of respiratory disease ‘seasonality’ which means it is far worse in the winter months. Who would have thought that respiratory disease could be worse in the winter? Well, certainly not Ferguson.

The massively China-connected Imperial College and its bizarre professor provided the excuse for the long-incubated Chinese model of human control to travel westward at lightning speed. Imperial College confirms on its website that it collaborates with the Chinese Research Institute; publishes more than 600 research papers every year with Chinese research institutions; has 225 Chinese staff; 2,600 Chinese students – the biggest international group; 7,000 former students living in China which is the largest group outside the UK; and was selected for a tour by China’s President Xi Jinping during his state visit to the UK in 2015. The college takes major donations from China and describes itself as the UK’s number one university collaborator with Chinese research institutions. The China communist/fascist government did not appear phased by the woeful predictions of Ferguson and Imperial when during the lockdown that Ferguson induced the college signed a five-year collaboration deal with China tech giant Huawei that will have Huawei’s indoor 5G network equipment installed at the college’s West London tech campus along with an ‘AI cloud platform’. The deal includes Chinese sponsorship of Imperial’s Venture Catalyst entrepreneurship competition. Imperial is an example of the enormous influence the Chinese government has within British and North American universities and research centres – and further afield. Up to 200 academics from more than a dozen UK universities are being investigated on suspicion of ‘unintentionally’ helping the Chinese government build weapons of mass destruction by ‘transferring world-leading research in advanced military technology such as aircraft, missile designs and cyberweapons’. Similar scandals have broken in the United States, but it’s all a coincidence. Imperial College serves the agenda in many other ways including the promotion of every aspect of the United Nations Agenda 21/2030 (the Great Reset) and produced computer models to show that human-caused ‘climate change’ is happening when in the real world it isn’t. Imperial College is driving the climate agenda as it drives the ‘Covid’ agenda (both Cult hoaxes) while Patrick Vallance, the UK government’s Chief Scientific Adviser on ‘Covid’, was named Chief Scientific Adviser to the UN ‘climate change’ conference known as COP26 hosted by the government in Glasgow, Scotland. ‘Covid’ and ‘climate’ are fundamentally connected.

Professor Woeful

From Imperial’s bosom came Neil Ferguson still advising government despite his previous disasters and it was announced early on that he and other key people like UK Chief Medical Adviser Chris Whitty had caught the ‘virus’ as the propaganda story was being sold. Somehow they managed to survive and we had Prime Minister Boris Johnson admitted to hospital with what was said to be a severe version of the ‘virus’ in this same period. His whole policy and demeanour changed when he returned to Downing Street. It’s a small world with these government advisors – especially in their communal connections to Gates – and Ferguson had partnered with Whitty to write a paper called ‘Infectious disease: Tough choices to reduce Ebola transmission’ which involved another scare-story that didn’t happen. Ferguson’s ‘models’ predicted that up to150, 000 could die from ‘mad cow disease’, or BSE, and its version in sheep if it was transmitted to humans. BSE was not transmitted and instead triggered by an organophosphate pesticide used to treat a pest on cows. Fewer than 200 deaths followed from the human form. Models by Ferguson and his fellow incompetents led to the unnecessary culling of millions of pigs, cattle and sheep in the foot and mouth outbreak in 2001 which destroyed the lives and livelihoods of farmers and their families who had often spent decades building their herds and flocks. Vast numbers of these animals did not have foot and mouth and had no contact with the infection. Another 'expert' behind the cull was Professor Roy Anderson, a computer modeller at Imperial College specialising in the epidemiology of *human*, not animal, disease. Anderson has served on the Bill and Melinda Gates Grand Challenges in Global Health advisory board and chairs another Gates-funded organisation. Gates is everywhere.

In a precursor to the 'Covid' script Ferguson backed closing schools 'for prolonged periods' over the swine flu 'pandemic' in 2009 and said it would affect a third of the world population if it continued to spread at the speed he claimed to be happening. His mates at Imperial College said much the same and a news report said: 'One of the authors, the epidemiologist and disease modeller Neil Ferguson, who sits on the World Health Organisation's emergency committee for the outbreak, said the virus had "full pandemic potential".' Professor Liam Donaldson, the Chris Whitty of his day as Chief Medical Officer, said the worst case could see 30 percent of the British people infected by swine flu with 65,000 dying. Ferguson and Donaldson were indeed proved correct when at the end of the year the number of deaths attributed to swine flu was 392. The term 'expert' is rather liberally applied unfortunately, not least to complete idiots. Swine flu 'projections' were great for GlaxoSmithKline (GSK) as millions rolled in for its Pandemrix influenza vaccine which led to brain damage with children most affected. The British government (taxpayers) paid out more than £60 million in compensation after GSK was given immunity from prosecution. Yet another 'Covid' déjà vu. Swine flu was supposed to have broken out in Mexico, but Dr Wolfgang Wodarg, a German doctor, former member of parliament and critic of the 'Covid' hoax, observed 'the spread of swine flu' in Mexico City at the time. He said: 'What we experienced in Mexico City was a very mild flu which did not kill more than usual – which killed even fewer people than usual.' Hyping the fear against all the facts is not unique to 'Covid' and has happened many times before. Ferguson is reported to have over-estimated the projected death toll of bird flu (H5N1) by some three million-fold, but bird flu vaccine makers again made a killing from the scare. This is some of the background to the Neil Ferguson who produced the perfectly-timed computer models in early 2020 predicting that half a million people would die in Britain without draconian lockdown and 2.2 million in the United States. Politicians panicked, people panicked, and lockdowns of alleged short duration were instigated to 'flatten the curve' of cases gleaned from a test not testing for the 'virus'. I said at the time that the public could forget the 'short duration' bit. This was an agenda to destroy the livelihoods of the population and force them into mass control through dependency and there was going to be nothing 'short' about it. American researcher Daniel Horowitz described the consequences of the 'models' spewed out by Gates-funded Ferguson and Imperial College:

> What led our government and the governments of many other countries into panic was a single Imperial College of UK study, funded by global warming activists, that predicted 2.2 million deaths if we didn't lock down the country. In addition, the reported 8-9% death rate in Italy scared us into thinking there was some other mutation of this virus that they got, which might have come here.
>
> Together with the fact that we were finally testing and had the ability to actually report new cases, we thought we were headed for a death spiral. But again … we can't flatten a curve if we don't know when the curve started.

How about it *never* started?

Giving them what they want

An investigation by German news outlet *Welt Am Sonntag (World on Sunday)* revealed how in March, 2020, the German government gathered together 'leading scientists from several research institutes and universities' and 'together, they were to produce a [modelling] paper that would serve as legitimization for further tough political measures'. The Cult agenda was justified by computer modelling not based on evidence or reality; it was specifically constructed to justify the Cult demand for lockdowns all over the world to destroy the independent livelihoods of the global population. All these modellers and everyone responsible for the 'Covid' hoax have a date with a trial like those in Nuremberg after World War Two when Nazis faced the consequences of their war crimes. These corrupt-beyond-belief 'modellers' wrote the paper according to government instructions and it said that that if lockdown measures were lifted then up to one million Germans would die from 'Covid-19' adding that some would die 'agonizingly at home, gasping for breath' unable to be treated by hospitals that couldn't cope. All lies. No matter – it gave the Cult all that it wanted. What did long-time government 'modeller' Neil Ferguson say? If the UK and the United States didn't lockdown half a million would die in Britain and 2.2 million Americans. Anyone see a theme here? 'Modellers' are such a crucial part of the lockdown strategy that we should look into their background and follow the money. Researcher Rosemary Frei produced an excellent article headlined 'The Modelling-paper Mafiosi'. She highlights a guy called John Edmunds, a British epidemiologist, and professor in the Faculty of Epidemiology and Population Health at the London School of Hygiene & Tropical Medicine. He studied at Imperial College. Edmunds is a member of government 'Covid' advisory bodies which have been dictating policy, the New and Emerging Respiratory Virus Threats Advisory Group (NERVTAG) and the Scientific Advisory Group for Emergencies (SAGE).

Ferguson, another member of NERVTAG and SAGE, led the way with the original 'virus' and Edmunds has followed in the 'variant' stage and especially the so-called UK or Kent variant known as the 'Variant of Concern' (VOC) B.1.1.7. He said in a co-written report for the Centre for Mathematical modelling of Infectious Diseases at the London School of Hygiene and Tropical Medicine, with input from the Centre's 'Covid-19' Working Group, that there was 'a realistic possibility that VOC B.1.1.7 is associated with an increased risk of death compared to non-VOC viruses'. Fear, fear, fear, get the vaccine, fear, fear, fear, get the vaccine. Rosemary Frei reveals that almost all the paper's authors and members of the modelling centre's 'Covid-19' Working Group receive funding from the Bill and Melinda Gates Foundation and/or the associated Gates-funded Wellcome Trust. The paper was published by e-journal *Medr χiv* which only publishes papers not peer-reviewed and the journal was established by an organisation headed by Facebook's Mark Zuckerberg and his missus. What a small world it is. Frei discovered that Edmunds is on the Scientific Advisory Board of the Coalition for Epidemic Preparedness Innovations (CEPI) which was established by the Bill and Melinda Gates Foundation, Klaus Schwab's Davos World Economic Forum and Big Pharma giant Wellcome. CEPI was 'launched in Davos [in 2017] to develop vaccines to stop future epidemics', according to its website. 'Our mission is to accelerate the development of vaccines against emerging infectious diseases and enable equitable access to these vaccines for people during outbreaks.' What kind people they are. Rosemary Frei reveals that Public Health England (PHE) director Susan Hopkins is an author of her organisation's non-peer-reviewed reports on 'new variants'. Hopkins is a professor of infectious diseases at London's Imperial College which is gifted tens of millions of dollars a year by the Bill and Melinda Gates Foundation. Gates-funded modelling disaster Neil Ferguson also co-authors Public Health England reports and he spoke in December, 2020, about the potential danger of the B.1.1.7. 'UK variant' promoted by Gates-funded modeller John Edmunds. When I come to the 'Covid vaccines' the 'new variants' will be shown for what they are – bollocks.

Connections, connections

All these people and modellers are lockdown-obsessed or, put another way, they demand what the Cult demands. Edmunds said in January, 2021, that to ease lockdowns too soon would be a disaster and they had to 'vaccinate much, much, much more widely than the elderly'. Rosemary Frei highlights that Edmunds is married to Jeanne Pimenta who is described in a LinkedIn profile as director of epidemiology at GlaxoSmithKline (GSK) and she held shares in the company. Patrick Vallance, co-chair of SAGE and the government's Chief Scientific Adviser, is a former executive of GSK and has a deferred bonus of shares in the company worth £600,000. GSK has serious business connections with Bill Gates and is collaborating with mRNA-'vaccine' company CureVac to make 'vaccines' for the new variants that Edmunds is talking about. GSK is planning a 'Covid vaccine' with drug giant Sanofi. Puppet Prime Minister Boris Johnson announced in the spring of 2021 that up to 60 million vaccine doses were to be made at the GSK facility at Barnard Castle in the English North East. Barnard Castle, with a population of just 6,000, was famously visited in breach of lockdown rules in April, 2020, by Johnson aide Dominic Cummings who said that he drove there 'to test his eyesight' before driving back to London. Cummings would be better advised to test his integrity – not that it would take long. The GSK facility had nothing to do with his visit then although I'm sure Patrick Vallance would have been happy to arrange an introduction and some tea and biscuits. Ruthless psychopath Gates has made yet another fortune from vaccines in collaboration with Big Pharma companies and gushes at the phenomenal profits to be made from vaccines – more than a 20-to-1 return as he told one interviewer. Gates also tweeted in December, 2019, with the foreknowledge of what was coming: 'What's next for our foundation? I'm particularly excited about what the next year could mean for one of the best buys in global health: vaccines.'

Modeller John Edmunds is a big promotor of vaccines as all these people appear to be. He's the dean of the London School of Hygiene & Tropical Medicine's Faculty of Epidemiology and Population Health which is primarily funded by the Bill and Melinda Gates Foundation and the Gates-established and funded GAVI vaccine alliance which is the Gates vehicle to vaccinate the world. The organisation Doctors Without Borders has described GAVI as being 'aimed more at supporting drug-industry desires to promote new products than at finding the most efficient and sustainable means for fighting the diseases of poverty'. But then that's why the psychopath Gates created it. John Edmunds said in a video that the London School of Hygiene & Tropical Medicine is involved in every aspect of vaccine development including large-scale clinical trials. He contends that mathematical modelling can show that vaccines protect individuals and society. That's on the basis of shit in and shit out, I take it. Edmunds serves on the UK Vaccine Network as does Ferguson and the government's foremost 'Covid' adviser, the grim-faced, dark-eyed Chris Whitty. The Vaccine Network says it works 'to support the government to identify and shortlist targeted investment opportunities for the most promising vaccines and vaccine technologies that will help combat infectious diseases with epidemic potential, and to address structural issues related to the UK's broader vaccine infrastructure'. Ferguson is acting Director of the Imperial College Vaccine Impact Modelling Consortium which has funding from the Bill and Melina Gates Foundation and the Gates-created GAVI 'vaccine alliance'. Anyone wonder why these characters see vaccines as the answer to every problem? Ferguson is wildly enthusiastic in his support for GAVI's campaign to vaccine children en masse in poor countries. You would expect someone like Gates who has constantly talked about the need to reduce the population to want to fund vaccines to keep more people alive. I'm sure that's why he does it. The John Edmunds London School of Hygiene & Tropical Medicine (LSHTM) has a Vaccines Manufacturing Innovation Centre which develops, tests and commercialises vaccines. Rosemary Frei writes:

> The vaccines centre also performs affiliated activities like combating 'vaccine hesitancy'. The latter includes the Vaccine Confidence Project. The project's stated purpose is, among other things, 'to provide analysis and guidance for early response and engagement with the public to ensure sustained confidence in vaccines and immunisation'. The Vaccine Confidence Project's director is LSHTM professor Heidi Larson. For more than a decade she's been researching how to combat vaccine hesitancy.

How the bloody hell can blokes like John Edmunds and Neil Ferguson with those connections and financial ties model 'virus' case and death projections for the government and especially in a way that gives their paymasters like Gates exactly what they want? It's insane, but this is what you find throughout the world.

'Covid' is not dangerous, oops, wait, yes it is

Only days before Ferguson's nightmare scenario made Jackboot Johnson take Britain into a China-style lockdown to save us from a deadly 'virus' the UK government website gov.uk was reporting something very different to Ferguson on a page of official government guidance for 'high consequence infectious diseases (HCID)'. It said this about 'Covid-19':

> As of 19 March 2020, COVID-19 *is no longer considered to be a high consequence infectious diseases (HCID) in the UK* [my emphasis]. The 4 nations public health HCID group made an interim recommendation in January 2020 to classify COVID-19 as an HCID. This was based on consideration of the UK HCID criteria about the virus and the disease with information available during the early stages of the outbreak.
>
> Now that more is known about COVID-19, the public health bodies in the UK have reviewed the most up to date information about COVID-19 against the UK HCID criteria. They have determined that several features have now changed; in particular, more information is available about mortality rates (low overall), and there is now greater clinical awareness and a specific and sensitive laboratory test, the availability of which continues to increase. The Advisory Committee on Dangerous Pathogens (ACDP) is also of the opinion that COVID-19 should no longer be classified as an HCID.

Soon after the government had been exposed for downgrading the risk they upgraded it again and everyone was back to singing from the same Cult hymn book. Ferguson and his fellow Gates clones indicated that lockdowns and restrictions would have to continue until a Gates-funded vaccine was developed. Gates said the same because Ferguson and his like were repeating the Gates script which is the Cult script. 'Flatten the curve' became an ongoing nightmare of continuing lockdowns with periods in between of severe restrictions in pursuit of destroying independent incomes and had nothing to do with protecting health about which the Cult gives not a shit. Why wouldn't Ferguson be pushing a vaccine 'solution' when he's owned by vaccine-obsessive Gates who makes a fortune from them and when Ferguson heads the Vaccine Impact Modelling Consortium at Imperial College funded by the Gates Foundation and GAVI, the ‘vaccine alliance’, created by Gates as his personal vaccine promotion operation? To compound the human catastrophe that Ferguson’s ‘models’ did so much to create he was later exposed for breaking his own lockdown rules by having sexual liaisons with his married girlfriend Antonia Staats at his home while she was living at another location with her husband and children. Staats was a ‘climate’ activist and senior campaigner at the Soros-funded Avaaz which I wouldn’t trust to tell me that grass is green. Ferguson had to resign as a government advisor over this hypocrisy in May, 2020, but after a period of quiet he was back being quoted by the ridiculous media on the need for more lockdowns and a vaccine rollout. Other government-advising ‘scientists’ from Imperial College’ held the fort in his absence and said lockdown could be indefinite until a vaccine was found. The Cult script was being sung by the payrolled choir. I said there was no intention of going back to ‘normal’ when the ‘vaccine’ came because the ‘vaccine’ is part of a very different agenda that I will discuss in Human 2.0. Why would the Cult want to let the world go back to normal when destroying that normal forever was the whole point of what was happening? House arrest, closing businesses and schools through lockdown, (un)social distancing and masks all followed the Ferguson fantasy models. Again as I predicted (these people are so predictable) when the ‘vaccine’ arrived we were told that house arrest, lockdown, (un)social distancing and masks would still have to continue. I will deal with the masks in the next chapter because they are of fundamental importance.

Where’s the ‘pandemic’?

Any mildly in-depth assessment of the figures revealed what was really going on. Cult-funded and controlled organisations still have genuine people working within them such is the number involved. So it is with Genevieve Briand, assistant program director of the Applied Economics master’s degree program at Johns Hopkins

University. She analysed the impact that 'Covid-19' had on deaths from *all* causes in the United States using official data from the CDC for the period from early February to early September, 2020. She found that allegedly 'Covid' *related*-deaths exceeded those from heart disease which she found strange with heart disease always the biggest cause of fatalities. Her research became even more significant when she noted the sudden decline in 2020 of *all* non-'Covid' deaths: 'This trend is completely contrary to the pattern observed in all previous years … the total decrease in deaths by other causes almost exactly equals the increase in deaths by Covid-19.' This was such a game, set and match in terms of what was happening that Johns Hopkins University deleted the article on the grounds that it 'was being used to support false and dangerous inaccuracies about the impact of the pandemic'. No – because it exposed the scam from official CDC figures and this was confirmed when those figures were published in January, 2021. Here we can see the effect of people dying from heart attacks, cancer, road accidents and gunshot wounds – *anything* – having 'Covid-19' on the death certificate along with those diagnosed from 'symptoms' who had even not tested positive with a test not testing for the 'virus'. I am not kidding with the gunshot wounds, by the way. Brenda Bock, coroner in Grand County, Colorado, revealed that two gunshot victims tested positive for the 'virus' within the previous 30 days and were therefore classified as 'Covid deaths'. Bock said: 'These two people had tested positive for Covid, but that's not what killed them. A gunshot wound is what killed them.' She said she had not even finished her investigation when the state listed the gunshot victims as deaths due to the 'virus'. The death and case figures for 'Covid-19' are an absolute joke and yet they are repeated like parrots by the media, politicians and alleged medical 'experts'. The official Cult narrative is the only show in town.

Genevieve Briand found that deaths from all causes were not exceptional in 2020 compared with previous years and a Spanish magazine published figures that said the same about Spain which was a 'Covid' propaganda hotspot at one point. *Discovery Salud*, a health and medicine magazine, quoted government figures which showed how 17,000 *fewer* people died in Spain in 2020 than in 2019 and more than 26,000 fewer than in 2018. The age-standardised mortality rate for England and Wales when age distribution is taken into account was significantly lower in 2020 than the 1970s, 80s and 90s, and was only the ninth highest since 2000. Where is the 'pandemic'?

Post mortems and autopsies virtually disappeared for 'Covid' deaths amid claims that 'virus-infected' bodily fluids posed a risk to those carrying out the autopsy. This was rejected by renowned German pathologist and forensic doctor Klaus Püschel who said that he and his staff had by then done 150 autopsies on 'Covid' patients with no problems at all. He said they were needed to know why some 'Covid' patients suffered blood clots and not severe respiratory infections. The 'virus' is, after all, called SARS or 'severe acute respiratory syndrome'. I highlighted in the spring of 2020 this phenomenon and quoted New York intensive care doctor Cameron Kyle-Sidell who posted a soon deleted YouTube video to say that they had been told to prepare to treat an infectious disease called 'Covid-19', but that was not what they were dealing with. Instead he likened the lung condition of the most severely ill patients to what you would expect with cabin depressurisation in a plane at 30,000 feet or someone dropped on the top of Everest without oxygen or acclimatisation. I have never said this is not happening to a small minority of alleged 'Covid' patients – I am saying this is not caused by a phantom 'contagious virus'. Indeed Kyle-Sidell said that 'Covid-19' was not the disease they were told was coming their way. 'We are operating under a medical paradigm that is untrue,' he said, and he believed they were treating the wrong disease: 'These people are being slowly starved of oxygen.' Patients would take off their oxygen masks in a state of fear and stress and while they were blue in the face on the brink of death. They did not look like patients dying of pneumonia. You can see why they don't want autopsies when their virus doesn't exist and there is another condition in some people that they don't wish to be uncovered. I should add here that the 5G system of millimetre waves was being rapidly introduced around the world in 2020 and even more so now as they fire 5G at the Earth from satellites. At 60 gigahertz within the 5G range that frequency interacts with the oxygen molecule and stops people breathing in sufficient oxygen to be absorbed into the bloodstream. They are installing 5G in schools and hospitals. The world is not mad or anything. 5G can cause major changes to the lungs and blood as I detail in *The Answer* and these consequences are labelled 'Covid-19', the alleged symptoms of which can be caused by 5G and other electromagnetic frequencies as cells respond to radiation poisoning.

The 'Covid death' scam

Dr Scott Jensen, a Minnesota state senator and medical doctor, exposed 'Covid' Medicare payment incentives to hospitals and death certificate manipulation. He said he was sent a seven-page document by the US Department of Health 'coaching' him on how to fill out death certificates which had never happened before. The document said that he didn't need to have a laboratory test for 'Covid-19' to put that on the death certificate and that shocked him when death certificates are supposed to be about facts. Jensen described how doctors had been 'encouraged, if not pressured' to make a diagnosis of 'Covid-19' if they thought it was probable or *'presumed'*. No positive test was necessary – not that this would have mattered anyway. He said doctors were told to diagnose 'Covid' by symptoms when these were the same as colds, allergies, other respiratory problems, and certainly with influenza which 'disappeared' in the 'Covid' era. A common sniffle was enough to get the dreaded verdict. Ontario authorities decreed that a single care home resident with *one* symptom from a long list must lead to the isolation of the entire home. Other courageous doctors like Jensen made the same point about death figure manipulation and how deaths by other causes were falling while 'Covid-19 deaths' were rising at the same rate due to re-diagnosis. Their videos rarely survive long on YouTube with its Cult-supporting algorithms courtesy of CEO Susan Wojcicki and her bosses at Google. Figure-tampering was so glaring and ubiquitous that even officials were letting it slip or outright saying it. UK chief scientific adviser Patrick Vallance said on one occasion that 'Covid' on the death certificate doesn't mean 'Covid' was the cause of death (so why the hell is it there?) and we had the rare sight of a BBC reporter telling the truth when she said: 'Someone could be successfully treated for Covid, in say April, discharged, and then in June, get run over by a bus and die … That person would still be counted as a Covid death in England.' Yet the BBC and the rest of the world media went on repeating the case and death figures as if they were real. Illinois Public Health Director Dr Ngozi Ezike revealed the deceit while her bosses must have been clenching their buttocks:

> If you were in a hospice and given a few weeks to live and you were then found to have Covid that would be counted as a Covid death. [There might be] a clear alternate cause, but it is still listed as a Covid death. So everyone listed as a Covid death doesn't mean that was the cause of the death, but that they had Covid at the time of death.

Yes, a 'Covid virus' never shown to exist and tested for with a test not testing for the 'virus'. In the first period of the pandemic hoax through the spring of 2020 the process began of designating almost everything a 'Covid' death and this has continued ever since. I sat in a restaurant one night listening to a loud conversation on the next table where a family was discussing in bewilderment how a relative who had no symptoms of 'Covid', and had died of a long-term problem, could have been diagnosed a death by the 'virus'. I could understand their bewilderment. If they read this book they will know why this medical fraud has been perpetrated the world over.

Some media truth shock

The media ignored the evidence of death certificate fraud until eventually one columnist did speak out when she saw it first-hand. Bel Mooney is a long-time national newspaper journalist in Britain currently working for the *Daily Mail*. Her article on February 19th, 2021, carried this headline: 'My dad Ted passed three Covid tests and died of a chronic illness yet he's officially one of Britain's 120,000 victims of the virus and is far from alone ... so how many more are there?' She told how her 99-year-old father was in a care home with a long-standing chronic obstructive pulmonary disease and vascular dementia. Maybe, but he was still aware enough to tell her from the start that there was no 'virus' and he refused the 'vaccine' for that reason. His death was not unexpected given his chronic health problems and Mooney said she was shocked to find that 'Covid-19' was declared the cause of death on his death certificate. She said this was a 'bizarre and unacceptable untruth' for a man with long-time health problems who had tested negative twice at the home for the 'virus'. I was also shocked by this story although not by what she said. I had been highlighting the death certificate manipulation for ten months. It was the confirmation that a professional full-time journalist only realised this was going on when it affected her directly and neither did she know that whether her dad tested positive or negative was irrelevant with the test not testing for the 'virus'. Where had she been? She said she did not believe in 'conspiracy theories' without knowing I'm sure that this and 'conspiracy theorists' were terms put into widespread circulation by the CIA in the 1960s to discredit those who did not accept the ridiculous official story of the Kennedy assassination. A blanket statement of 'I don't believe in conspiracy theories' is always bizarre. The dictionary definition of the term alone means the world is drowning in conspiracies. What she said was even more daft when her dad had just been affected by the 'Covid' conspiracy. Why else does she think that 'Covid-19' was going on the death certificates of people who died of something else?

To be fair once she saw from personal experience what was happening she didn't mince words. Mooney was called by the care home on the morning of February 9th to be told her father had died in his sleep. When she asked for the official cause of death what came back was 'Covid-19'. Mooney challenged this and was told there had been deaths from Covid on the dementia floor (confirmed by a test not testing for the 'virus') so they considered it 'reasonable to assume'. 'But doctor,' Mooney rightly protested, 'an assumption isn't a diagnosis.' She said she didn't blame the perfectly decent and sympathetic doctor – 'he was just doing his job'. Sorry, but that's *bullshit*. He wasn't doing his job at all. He was putting a false cause of death on the death certificate and that is a criminal offence for which he should be brought to account and the same with the millions of doctors worldwide who have done the same. They were not doing their job they were following orders and that must not wash at new Nuremberg trials any more than it did at the first ones. Mooney's doctor was 'assuming' (presuming) as he was told to, but 'just following orders' makes no difference to his actions. A doctor's job is to serve the patient and the truth, not follow orders, but that's what they have done all over the world and played a central part in making the 'Covid' hoax possible with all its catastrophic consequences for humanity. Shame on them and they must answer for their actions. Mooney said her disquiet worsened when she registered her father's death by telephone and was told by the registrar there had been very many other cases like hers where 'the deceased' had not tested positive for 'Covid' yet it was recorded as the cause of death. The test may not matter, but those involved at their level *think* it matters and it shows a callous disregard for accurate diagnosis. The pressure to do this is coming from the top of the national 'health' pyramids which in turn obey the World Health Organization which obeys Gates and the Cult. Mooney said the registrar agreed that this must distort the national figures adding that 'the strangest thing is that every winter we record countless deaths from flu, and this winter there have been none. Not one!' She asked if the registrar thought deaths from flu were being misdiagnosed and lumped together with 'Covid' deaths. The answer was a 'puzzled yes'. Mooney said that the funeral director said the same about 'Covid' deaths which had nothing to do with 'Covid'. They had lost count of the number of families upset by this and other funeral companies in different countries have had the same experience. Mooney wrote:

> The nightly shroud-waving and shocking close-ups of pain imposed on us by the TV news bewildered and terrified the population into eager compliance with lockdowns. We were invited to 'save the NHS' and to grieve for strangers – the real-life loved ones behind those shocking death counts. Why would the public imagine what I now fear, namely that the way Covid-19 death statistics are compiled might make the numbers seem greater than they are?

Oh, just a little bit – like 100 percent.

Do the maths

Mooney asked why a country would wish to skew its mortality figures by wrongly certifying deaths? What had been going on? Well, if you don't believe in conspiracies you will never find the answer which is that *it's a conspiracy*. She did, however, describe what she had discovered as a 'national scandal'. In reality it's a global scandal and happening everywhere. Pillars of this conspiracy were all put into place before the button was pressed with the Drosten PCR protocol and high amplifications to produce the cases and death certificate changes to secure illusory 'Covid' deaths. Mooney notes that normally two doctors were needed to certify a death, with one having to know the patient, and how the rules were changed in the spring of 2020 to allow one doctor to do this. In the same period 'Covid deaths' were decreed to be all cases where Covid-19 was put on the death certificate even without a positive test or any symptoms. Mooney asked: 'How many of the 30,851 (as of January 15) care home resident deaths with Covid-19 on the certificate (32.4 per cent of all deaths so far) were based on an assumption, like that of my father? And what has that done to our national psyche?'All of them is the answer to the first question and it has devastated and dismantled the national psyche, actually the global psyche, on a colossal scale. In the UK case and death data is compiled by organisations like Public Health England (PHE) and the Office for National Statistics (ONS). Mooney highlights the insane policy of counting a death from any cause as 'Covid-19' if this happens within 28 days of a positive test (with a test not testing for the 'virus') and she points out that ONS statistics reflect deaths 'involving Covid' 'or due to Covid' which meant in practice any death where ‘Covid-19’ was mentioned on the death certificate. She described the consequences of this fraud:

> Most people will accept the narrative they are fed, so panicky governments here and in Europe witnessed the harsh measures enacted in totalitarian China and jumped into lockdown. Headlines about Covid deaths tolled like the knell that would bring doomsday to us all. Fear stalked our empty streets. Politicians parroted the frankly ridiculous aim of ‘zero Covid’ and shut down the economy, while most British people agreed that lockdown was essential and (astonishingly to me, as a patriotic Brit) even wanted more restrictions.
>
> For what? Lies on death certificates? Never mind the grim toll of lives ruined, suicides, schools closed, rising inequality, depression, cancelled hospital treatments, cancer patients in a torture of waiting, poverty, economic devastation, loneliness, families kept apart, and so on. How many lives have been lost as a direct result of lockdown?

She said that we could join in a national chorus of shock and horror at reaching the 120,000 death toll which was surely certain to have been totally skewed all along, but what about the human cost of lockdown justified by these ‘death figures’? *The British Medical Journal* had reported a 1,493 percent increase in cases of children taken to Great Ormond Street Hospital with abusive head injuries alone and then there was the effect on families:

> Perhaps the most shocking thing about all this is that families have been kept apart – and obeyed the most irrational, changing rules at the whim of government – because they believed in the statistics. They succumbed to fear, which his generation rejected in that war fought for freedom. Dad (God rest his soul) would be angry. And so am I.

Another theme to watch is that in the winter months when there are more deaths from all causes they focus on ‘Covid’ deaths and in the summer when the British Lung Foundation says respiratory disease plummets by 80 percent they rage on about ‘cases’. Either way fascism on population is always the answer.

Nazi eugenics in the 21st century

Elderly people in care homes have been isolated from their families month after lonely month with no contact with relatives and grandchildren who were banned from seeing them. We were told that lockdown fascism was to ‘protect the vulnerable’ like elderly people. At the same time Do Not Resuscitate (DNR) orders were placed on their medical files so that if they needed resuscitation it wasn’t done and ‘Covid-19’ went on their death certificates. Old people were not being ‘protected’ they were being culled – murdered in truth. DNR orders were being decreed for disabled and young people with learning difficulties or psychological problems. The UK Care Quality Commission, a non-departmental body of the Department of Health and Social Care, found that 34 percent of those working in health and social care were pressured into placing ‘do not attempt cardiopulmonary resuscitation’ orders on ‘Covid’ patients who suffered from disabilities and learning difficulties without involving the patient or their families in the decision. UK judges ruled that an elderly woman with dementia should have the DNA-manipulating ‘Covid vaccine’ against her son’s wishes and that a man with severe learning difficulties should have the jab despite his family’s objections. Never mind that many had already died. The judiciary always supports doctors and government in fascist dictatorships. They wouldn’t dare do otherwise. A horrific video was posted showing fascist officers from Los Angeles police forcibly giving the ‘Covid’ shot to women with special needs who were screaming that they didn’t want it. The same fascists are seen giving the jab to a sleeping elderly woman in a care home. This is straight out of the Nazi playbook. Hitler’s Nazis committed mass murder of the mentally ill and physically disabled throughout Germany and occupied territories in the programme that became known as Aktion T4, or just T4. Sabbatian-controlled Hitler and his grotesque crazies set out to kill those they considered useless and unnecessary. The Reich Committee for the Scientific Registering of Hereditary and Congenital Illnesses registered the births of babies identified by physicians to have ‘defects’. By 1941 alone more than 5,000 children were murdered by the state and it is estimated that in total the number of innocent people killed in Aktion T4 was between 275,000 and 300,000. Parents were told their children had been sent away for ‘special treatment’ never to return. It is rather pathetic to see claims about plans for new extermination camps being dismissed today when the same force behind current events did precisely that 80 years ago. Margaret Sanger was a Cult operative who used 'birth control' to sanitise her programme of eugenics. Organisations she founded became what is now Planned Parenthood. Sanger proposed that 'the whole dysgenic population would have its choice of segregation or sterilization'. These included epileptics, 'feeble-minded', and prostitutes. Sanger opposed charity because it perpetuated 'human waste'. She reveals the Cult mentality and if anyone thinks that extermination camps are a 'conspiracy theory' their naivety is touching if breathtakingly stupid.

If you don't believe that doctors can act with callous disregard for their patients it is worth considering that doctors and medical staff agreed to put government-decreed DNR orders on medical files and do nothing when resuscitation is called for. I don't know what you call such people in your house. In mine they are Nazis from the Josef Mengele School of Medicine. Phenomenal numbers of old people have died worldwide from the effects of lockdown, depression, lack of treatment, the 'vaccine' (more later) and losing the will to live. A common response at the start of the manufactured pandemic was to remove old people from hospital beds and transfer them to nursing homes. The decision would result in a mass cull of elderly people in those homes through lack of treatment – *not* 'Covid'. Care home whistleblowers have told how once the 'Covid' era began doctors would not come to their homes to treat patients and they were begging for drugs like antibiotics that often never came. The most infamous example was ordered by New York governor Andrew Cuomo, brother of a moronic CNN host, who amazingly was given an Emmy Award for his handling of the 'Covid crisis' by the ridiculous Wokers that hand them out. Just how ridiculous could be seen in February, 2021, when a Department of Justice and FBI investigation began into how thousands of old people in New York died in nursing homes after being discharged from hospital to make way for 'Covid' patients on Cuomo's say-so – and how he and his staff covered up these facts. This couldn't have happened to a nicer psychopath. Even then there was a 'Covid' spin. Reports said that thousands of old people who tested positive for 'Covid' in hospital were transferred to nursing homes to both die of 'Covid' and transmit it to others. No – they were in hospital because they were ill and the fact that they tested positive with a test not testing for the 'virus' is irrelevant. They were ill often with respiratory diseases ubiquitous in old people near the end of their lives. Their transfer out of hospital meant that their treatment stopped and many would go on to die.

They're old. Who gives a damn?

I have exposed in the books for decades the Cult plan to cull the world's old people and even to introduce at some point what they call a 'demise pill' which at a certain age everyone would take and be out of here by law. In March, 2021, Spain legalised euthanasia and assisted suicide following the Netherlands, Belgium, Luxembourg and Canada on the Tiptoe to the demise pill. Treatment of old people by many 'care' homes has been a disgrace in the 'Covid' era. There are many, many, caring staff – I know some. There have, however, been legions of stories about callous treatment of old people and their families. Police were called when families came to take their loved ones home in the light of isolation that was killing them. They became prisoners of the state. Care home residents in insane, fascist Ontario, Canada, were not allowed to leave their *room* once the 'Covid' hoax began. UK staff have even wheeled elderly people away from windows where family members were talking with them. Oriana Criscuolo from Stockport in the English North West dropped off some things for her 80-year-old father who has Parkinson's disease and dementia and she wanted to wave to him through a ground-floor window. She was told that was 'illegal'. When she went anyway they closed the curtains in the middle of the day. Oriana said:

> It's just unbelievable. I cannot understand how care home staff – people who are being paid to care – have become so uncaring. Their behaviour is inhumane and cruel. It's beyond belief.

She was right and this was not a one-off. What a way to end your life in such loveless circumstances. UK registered nurse Nicky Millen, a proper old school nurse for 40 years, said that when she started her career care was based on dignity, choice, compassion and empathy. Now she said 'the things that are important to me have gone out of the window.' She was appalled that people were dying without their loved ones and saying goodbye on iPads. Nicky described how a distressed 89-year-old lady stroked her face and asked her 'how many paracetamol would it take to finish me off'. Life was no longer worth living while not seeing her family. Nicky said she was humiliated in front of the ward staff and patients for letting the lady stroke her face and giving her a cuddle. Such is the dehumanisation that the 'Covid' hoax has brought to the surface. Nicky worked in care homes where patients told her they were being held prisoner. 'I want to live until I die', one said to her. 'I had a lady in tears because she hadn't seen her great-grandson.' Nicky was compassionate old school meeting psychopathic New Normal. She also said she had worked on a 'Covid' ward with no 'Covid' patients. Jewish writer Shai Held wrote an article in March, 2020, which was headlined 'The Staggering, Heartless Cruelty Toward the Elderly'. What he described was happening from the earliest days of lockdown. He said 'the elderly' were considered a group and not unique individuals (the way of the Woke). Shai Held said:

> Notice how the all-too-familiar rhetoric of dehumanization works: 'The elderly' are bunched together as a faceless mass, all of them considered culprits and thus effectively deserving of the suffering the pandemic will inflict upon them. Lost entirely is the fact that the elderly are individual human beings, each with a distinctive face and voice, each with hopes and dreams, memories and regrets, friendships and marriages, loves lost and loves sustained.

'The elderly' have become another dehumanised group for which anything goes and for many that has resulted in cold disregard for their rights and their life. The distinctive face that Held talks about is designed to be deleted by masks until everyone is part of a faceless mass.

'War-zone' hospitals myth

Again and again medical professionals have told me what was really going on and how hospitals 'overrun like war zones' according to the media were virtually empty. The mantra from medical whistleblowers was please don't use my name or my career is over. Citizen journalists around the world sneaked into hospitals to film evidence exposing the 'war-zone' lie. They really *were* largely empty with closed wards and operating theatres. I met a hospital worker in my town on the Isle of Wight during the first lockdown in 2020 who said the only island hospital had never been so quiet. Lockdown was justified by the psychopaths to stop hospitals being overrun. At the same time that the island hospital was near-empty the military arrived here to provide *extra beds*. It was all propaganda to ramp up the fear to ensure compliance with fascism as were never-used temporary hospitals with thousands of beds known as Nightingales and never-used make-shift mortuaries opened by the criminal UK government. A man who helped to install those extra island beds attributed to the army said they were never used and the hospital was empty. Doctors and nurses 'stood around talking or on their phones, wandering down to us to see what we were doing'. There were no masks or social distancing. He accused the useless local island paper, the *County Press*, of 'pumping the fear as if our hospital was overrun and we only have one so it should have been'. He described ambulances parked up with crews outside in deck chairs. When his brother called an ambulance he was told there was a two-hour backlog which he called 'bullshit'. An old lady on the island fell 'and was in a bad way', but a caller who rang for an ambulance was told the situation wasn't urgent enough. Ambulance stations were working under capacity while people would hear ambulances with sirens blaring driving through the streets. When those living near the stations realised what was going on they would follow them as they left, circulated around an urban area with the sirens going, and then came back without stopping. All this was to increase levels of fear and the same goes for the 'ventilator shortage crisis' that cost tens of millions for hastily produced ventilators never to be used.

Ambulance crews that agreed to be exploited in this way for fear propaganda might find themselves a mirror. I wish them well with that. Empty hospitals were the obvious consequence of treatment and diagnoses of non-'Covid' conditions cancelled and those involved handed a death sentence. People have been dying at home from undiagnosed and untreated cancer, heart disease and other life-threatening conditions to allow empty hospitals to deal with a 'pandemic' that wasn't happening.

Death of the innocent

'War-zones' have been laying off nursing staff, even doctors where they can. There was no work for them. Lockdown was justified by saving lives and protecting the vulnerable they were actually killing with DNR orders and preventing empty hospitals being 'overrun'. In Britain the mantra of stay at home to 'save the NHS' was everywhere and across the world the same story was being sold when it was all lies. Two California doctors, Dan Erickson and Artin Massihi at Accelerated Urgent Care in Bakersfield, held a news conference in April, 2020, to say that intensive care units in California were 'empty, essentially', with hospitals shutting floors, not treating patients and laying off doctors. The California health system was working at minimum capacity 'getting rid of doctors because we just don't have the volume'. They said that people with conditions such as heart disease and cancer were not coming to hospital out of fear of 'Covid-19'. Their video was deleted by Susan Wojcicki's Cult-owned YouTube after reaching five million views. Florida governor Ron Desantis, who rejected the severe lockdowns of other states and is being targeted for doing so, said that in March, 2020, every US governor was given models claiming they would run out of hospital beds in days. That was never going to happen and the 'modellers' knew it. Deceit can be found at every level of the system. Urgent children's operations were cancelled including fracture repairs and biopsies to spot cancer. Eric Nicholls, a consultant paediatrician, said 'this is obviously concerning and we need to return to normal operating and to increase capacity as soon as possible'. Psychopaths in power were rather less concerned *because* they are psychopaths. Deletion of urgent care and diagnosis has been happening all over the world and how many kids and others have died as a result of the actions of these cold and heartless lunatics dictating 'health' policy? The number must be stratospheric. Richard Sullivan, professor of cancer and global health at King's College London, said people feared 'Covid' more than cancer such was the campaign of fear. 'Years of lost life will be quite dramatic', Sullivan said, with 'a huge amount of avoidable mortality'. Sarah Woolnough, executive director for policy at Cancer Research UK, said there had been a 75 percent drop in urgent referrals to hospitals by family doctors of people with suspected cancer. Sullivan said that 'a lot of services have had to scale back – we've seen a dramatic decrease in the amount of elective cancer surgery'. Lockdown deaths worldwide has been absolutely fantastic with the *New York Post* reporting how data confirmed that 'lockdowns end more lives than they save':

> There was a sharp decline in visits to emergency rooms and an increase in fatal heart attacks because patients didn't receive prompt treatment. Many fewer people were screened for cancer. Social isolation contributed to excess deaths from dementia and Alzheimer's.
>
> Researchers predicted that the social and economic upheaval would lead to tens of thousands of "deaths of despair" from drug overdoses, alcoholism and suicide. As unemployment surged and mental-health and substance-abuse treatment programs were interrupted, the reported levels of anxiety, depression and suicidal thoughts increased dramatically, as did alcohol sales and fatal drug overdoses.

This has been happening while nurses and other staff had so much time on their hands in the 'war-zones' that Tic-Tok dancing videos began appearing across the Internet with medical staff dancing around in empty wards and corridors as people died at home from causes that would normally have been treated in hospital.

Mentions in dispatches

One brave and truth-committed whistleblower was Louise Hampton, a call handler with the UK NHS who made a viral Internet video saying she had done 'fuck all' during the 'pandemic' which was ‘a load of bollocks’. She said that ‘Covid-19’ was rebranded flu and of course she lost her job. This is what happens in the medical and endless other professions now when you tell the truth. Louise filmed inside ‘war-zone’ accident and emergency departments to show they were empty and I mean *empty* as in no one there. The mainstream media could have done the same and blown the gaff on the whole conspiracy. They haven’t to their eternal shame. Not that most ‘journalists’ seem capable of manifesting shame as with the psychopaths they slavishly repeat without question. The relative few who were admitted with serious health problems were left to die alone with no loved ones allowed to see them because of ‘Covid’ rules and they included kids dying without the comfort of mum and dad at their bedside while the evil behind this couldn’t give a damn. It was all good fun to them. A Scottish NHS staff nurse publicly quit in the spring of 2021 saying: ‘I can no longer be part of the lies and the corruption by the government.’ She said hospitals ‘aren’t full, the beds aren’t full, beds have been shut, wards have been shut’. Hospitals were never busy throughout ‘Covid’. The staff nurse said that Nicola Sturgeon, tragically the leader of the Scottish government, was on television saying save the hospitals and the NHS – ‘but the beds are empty’ and ‘we’ve not seen flu, we always see flu every year’. She wrote to government and spoke with her union Unison (the unions are Cult-compromised and *useless*, but nothing changed. Many of her colleagues were scared of losing their jobs if they spoke out as they wanted to. She said nursing staff were being affected by wearing masks all day and ‘my head is splitting every shift from wearing a mask’. The NHS is part of the fascist tyranny and must be dismantled so we can start again with human beings in charge. (Ironically, hospitals were reported to be busier again when official ‘Covid’ cases *fell* in spring/summer of 2021 and many other conditions required treatment at the same time as *the fake vaccine rollout*.)

I will cover the ‘Covid vaccine’ scam in detail later, but it is another indicator of the sickening disregard for human life that I am highlighting here. The DNA-manipulating concoctions do not fulfil the definition of a ‘vaccine’, have never been used on humans before and were given only emergency approval because trials were not completed and they continued using the unknowing public. The result was what a NHS senior nurse with responsibility for ‘vaccine’ procedure said was ‘genocide’. She said the ‘vaccines’ were not ‘vaccines’. They had not been shown to be safe and claims about their effectiveness by drug companies were ‘poetic licence’. She described what was happening as a ‘horrid act of human annihilation’. The nurse said that management had instigated a policy of not providing a Patient Information Leaflet (PIL) before people were ‘vaccinated’ even though health care professionals are supposed to do this according to protocol. Patients should also be told that they are taking part in an ongoing clinical trial. Her challenges to what is happening had seen her excluded from meetings and ridiculed in others. She said she was told to ‘watch my step … or I would find myself surplus to requirements’. The nurse, who spoke anonymously in fear of her career, said she asked her NHS manager why he/she was content with taking part in genocide against those having the ‘vaccines’. The reply was that everyone had to play their part and to ‘put up, shut up, and get it done’. Government was ‘leaning heavily’ on NHS management which was clearly leaning heavily on staff. This is how the global ‘medical’ hierarchy operates and it starts with the Cult and its World Health Organization.

She told the story of a doctor who had the Pfizer jab and when questioned had no idea what was in it. The doctor had never read the literature. We have to stop treating doctors as intellectual giants when so many are moral and medical pygmies. The doctor did not even know that the ‘vaccines’ were not fully approved or that their trials were ongoing. They were, however, asking their patients if they minded taking part in follow-ups for research purposes – yes, the *ongoing clinical trial*. The nurse said the doctor’s ignorance was not rare and she had spoken to a hospital consultant who had the jab without any idea of the background or that the ‘trials’ had not been completed. Nurses and pharmacists had shown the same ignorance.

‘My NHS colleagues have forsaken their duty of care, broken their code of conduct – Hippocratic Oath – and have been brainwashed just the same as the majority of the UK public through propaganda …’ She said she had not been able to recruit a single NHS colleague, doctor, nurse or pharmacist to stand with her and speak out. Her union had refused to help. She said that if the genocide came to light she would not hesitate to give evidence at a Nuremberg-type trial against those in power who could have affected the outcomes but didn’t.

And all for what?

To put the nonsense into perspective let’s say the ‘virus’ does exist and let’s go completely crazy and accept that the official manipulated figures for cases and deaths are accurate. *Even then* a study by Stanford University epidemiologist Dr John Ioannidis published on the World Health Organization website produced an average infection to fatality rate of … *0.23 percent!* Ioannidis said: ‘If one could sample equally from all locations globally, the median infection fatality rate might even be substantially lower than the 0.23% observed in my analysis.’ For healthy people under 70 it was … *0.05 percent*! This compares with the 3.4 percent claimed by the Cult-owned World Health Organization when the hoax was first played and maximum fear needed to be generated. An updated Stanford study in April, 2021, put the ‘infection’ to ‘fatality’ rate at just 0.15 percent. Another team of scientists led by Megan O’Driscoll and Henrik Salje studied data from 45 countries and published their findings on the Nature website. For children and young people the figure is so small it virtually does not register although authorities will be hyping dangers to the young when they introduce DNA-manipulating ‘vaccines’ for children. The O’Driscoll study produced an average infection-fatality figure of 0.003 for children from birth to four; 0.001 for 5 to 14; 0.003 for 15 to 19; and it was still only 0.456 up to 64. To claim that children must be ‘vaccinated’ to protect them from ‘Covid’ is an obvious lie and so there must be another reason and there is. What’s more the average age of a ‘Covid’ death is akin to the average age that people die in general. The average age of death in England is about 80 for men and 83 for women. The average age of death from alleged 'Covid' is between 82 and 83. California doctors, Dan Erickson and Artin Massihi, said at their April media conference that projection models of millions of deaths had been 'woefully inaccurate'. They produced detailed figures showing that Californians had a 0.03 chance of dying from 'Covid' based on the number of people who tested positive (with a test not testing for the 'virus'). Erickson said there was a 0.1 percent chance of dying from 'Covid' in the *state* of New York, not just the city, and a 0.05 percent chance in Spain, a centre of 'Covid-19' hysteria at one stage. The Stanford studies supported the doctors' data with fatality rate estimates of 0.23 and 0.15 percent. How close are these figures to my estimate of *zero*? Death-rate figures claimed by the World Health Organization at the start of the hoax were some 15 times higher. The California doctors said there was no justification for lockdowns and the economic devastation they caused. Everything they had ever learned about quarantine was that you quarantine the *sick* and not the healthy. They had never seen this before and it made no medical sense.

Why in the in the light of all this would governments and medical systems the world over say that billions must go under house arrest; lose their livelihood; in many cases lose their mind, their health and their life; force people to wear masks dangerous to health and psychology; make human interaction and even family interaction a criminal offence; ban travel; close restaurants, bars, watching live sport, concerts, theatre, and any activity involving human togetherness and discourse; and closing schools to isolate children from their friends and cause many to commit suicide in acts of hopelessness and despair? The California doctors said lockdown consequences included increased child abuse, partner abuse, alcoholism, depression, and other impacts they were seeing every day. Who would do that to the entire human race if not mentally-ill psychopaths of almost unimaginable extremes like Bill Gates? We must face the reality of what we are dealing with and come out of denial. Fascism and tyranny are made possible only by the target population submitting and acquiescing to fascism and tyranny. The whole of human history shows that to be true. Most people naively and unquestioning believed what they were told about a 'deadly virus' and meekly and weakly submitted to house arrest. Those who didn't believe it – at least in total – still submitted in fear of the consequences of not doing so. For the rest who wouldn't submit draconian fines have been imposed, brutal policing by psychopaths *for* psychopaths, and condemnation from the meek and weak who condemn the Pushbackers on behalf of the very force that has them, too, in its gunsights. 'Pathetic' does not even begin to suffice. Britain's brainless 'Health' Secretary Matt Hancock warned anyone lying to border officials about returning from a list of 'hotspot' countries could face a jail sentence of up to ten years which is more than for racially-aggravated assault, incest and attempting to have sex with a child under 13. Hancock is a lunatic, but he has the state apparatus behind him in a Cult-led chain reaction and the same with UK 'Vaccine Minister' Nadhim Zahawi, a prominent member of the mega-Cult secret society, Le Cercle, which featured in my earlier books. The Cult enforces its will on governments and medical systems; government and medical systems enforce their will on business and police; business enforces its will on staff who enforce it on customers; police enforce the will of the Cult on the population and play their essential part in creating a world of fascist control that their own children and grandchildren will have to live in their entire lives. It is a hierarchical pyramid of imposition and acquiescence and, yes indeedy, of clinical insanity.

Does anyone bright enough to read this book have to ask what the answer is? I think not, but I will reveal it anyway in the fewest of syllables: Tell the psychos and their moronic lackeys to fuck off and let's get on with our lives. We are many – They are few.

CHAPTER SEVEN

War on your mind

One believes things because one has been conditioned to believe them
Aldous Huxley, *Brave New World*

I have described the 'Covid' hoax as a 'Psyop' and that is true in every sense and on every level in accordance with the definition of that term which is psychological warfare. Break down the 'Covid pandemic' to the foundation themes and it is psychological warfare on the human individual and collective mind.

The same can be said for the entire human belief system involving every subject you can imagine. Huxley was right in his contention that people believe what they are conditioned to believe and this comes from the repetition throughout their lives of the same falsehoods. They spew from government, corporations, media and endless streams of 'experts' telling you what the Cult wants you to believe and often believing it themselves (although *far* from always). 'Experts' are rewarded with 'prestigious' jobs and titles and as agents of perceptual programming with regular access to the media. The Cult has to control the narrative – control *information* – or they lose control of the vital, crucial, without-which-they-cannot-prevail public perception of reality. The foundation of that control today is the Internet made possible by the Defense Advanced Research Projects Agency (DARPA), the incredibly sinister technological arm of the Pentagon. The Internet is the result of military technology.

DARPA openly brags about establishing the Internet which has been a long-term project to lasso the minds of the global population. I have said for decades the plan is to control information to such an extreme that eventually no one would see or hear anything that the Cult does not approve. We are closing in on that end with ferocious censorship since the 'Covid' hoax began and in my case it started back in the 1990s in terms of books and speaking venues. I had to create my own publishing company in 1995 precisely because no one else would publish my books even then. I think they're all still running.

Cult Internet

To secure total control of information they needed the Internet in which pre-programmed algorithms can seek out 'unclean' content for deletion and even stop it being posted in the first place. The Cult had to dismantle print and non-Internet broadcast media to ensure the transfer of information to the appropriate-named 'Web' – a critical expression of the *Cult* web. We've seen the ever-quickening demise of traditional media and control of what is left by a tiny number of corporations operating worldwide. Independent journalism in the mainstream is already dead and never was that more obvious than since the turn of 2020. The Cult wants all information communicated via the Internet to globally censor and allow the plug to be pulled any time. Lockdowns and forced isolation has meant that communication between people has been through electronic means and no longer through face-to-face discourse and discussion. Cult psychopaths have targeted the bars, restaurants, sport, venues and meeting places in general for this reason. None of this is by chance and it's to stop people gathering in any kind of privacy or number while being able to track and monitor all Internet communications and block them as necessary. Even private messages between individuals have been censored by these fascists that control Cult fronts like Facebook, Twitter, Google and YouTube which are all officially run by Sabbatian place-people and from the background by higher-level Sabbatian place people.

Facebook, Google, Amazon and their like were seed-funded and supported into existence with money-no-object infusions of funds either directly or indirectly from DARPA and CIA technology arm In-Q-Tel. The Cult plays the long game and prepares very carefully for big plays like 'Covid'. Amazon is another front in the psychological war and pretty much controls the global market in book sales and increasingly publishing. Amazon's limitless funds have deleted fantastic numbers of independent publishers to seize global domination on the way to deciding which books can be sold and circulated and which cannot. Moves in that direction are already happening. Amazon's leading light Jeff Bezos is the grandson of Lawrence Preston Gise who worked with DARPA predecessor ARPA. Amazon has big connections to the CIA and the Pentagon. The plan I have long described went like this:

1. Employ military technology to establish the Internet.

2. Sell the Internet as a place where people can freely communicate without censorship and allow that to happen until the Net becomes the central and irreversible pillar of human society. If the Internet had been highly censored from the start many would have rejected it.

3. Fund and manipulate major corporations into being to control the circulation of information on your Internet using cover stories about geeks in garages to explain how they came about. Give them unlimited funds to expand rapidly with no need to make a profit for years while non-Cult companies who need to balance the books cannot compete. You know that in these circumstances your Googles, YouTubes, Facebooks and Amazons are going to secure near monopolies by either crushing or buying up the opposition.

4. Allow freedom of expression on both the Internet and communication platforms to draw people in until the Internet is the central and irreversible pillar of human society and your communication corporations have reached a stage of near monopoly domination.

5. Then unleash your always-planned frenzy of censorship on the basis of 'where else are you going to go?' and continue to expand that until nothing remains that the Cult does not want its human targets to see.

The process was timed to hit the 'Covid' hoax to ensure the best chance possible of controlling the narrative which they knew they had to do at all costs. They were, after all, about to unleash a 'deadly virus' that didn't really exist. If you do that in an environment of free-flowing information and opinion you would be dead in the water before you could say Gates is a psychopath. The network was in place through which the Cult-created-and-owned World Health Organization could dictate the 'Covid' narrative and response policy slavishly supported by Cult-owned Internet communication giants and mainstream media while those telling a different story were censored. Google, YouTube, Facebook and Twitter openly announced that they would do this. What else would we expect from Cult-owned operations like Facebook which former executives have confirmed set out to make the platform more addictive than cigarettes and coldly manipulates emotions of its users to sow division between people and groups and scramble the minds of the young? If Zuckerberg lives out the rest of his life without going to jail for crimes against humanity, and most emphatically against the young, it will be a travesty of justice. Still, no matter, cause and effect will catch up with him eventually and the same with Sergey Brin and Larry Page at Google with its CEO Sundar Pichai who fix the Google search results to promote Cult narratives and hide the opposition. Put the same key words into Google and other search engines like DuckDuckGo and you will see how different results can be. Wikipedia is another intensely biased 'encyclopaedia' which skews its content to the Cult agenda. YouTube links to Wikipedia's version of 'Covid' and 'climate change' on video pages in which experts in their field offer a different opinion (even that is increasingly rare with Wojcicki censorship). Into this 'Covid' silence-them network must be added government media censors, sorry 'regulators', such as Ofcom in the UK which imposed tyrannical restrictions on British broadcasters that had the effect of banning me from ever appearing. Just to debate with me about my evidence and views on 'Covid' would mean breaking the fascistic impositions of Ofcom and its CEO career government bureaucrat Melanie Dawes. Gutless British broadcasters tremble at the very thought of fascist Ofcom.

Psychos behind 'Covid'

The reason for the ‘Covid’ catastrophe in all its facets and forms can be seen by whom and what is driving the policies worldwide in such a coordinated way. Decisions are not being made to protect health, but to target psychology. The dominant group guiding and ‘advising’ government policy are not medical professionals. They are psychologists and behavioural scientists. Every major country has its own version of this phenomenon and I’ll use the British example to show how it works. In many ways the British version has been affecting the wider world in the form of the huge behaviour manipulation network in the UK which operates in other countries. The network involves private companies, government, intelligence and military. The Cabinet Office is at the centre of the government ‘Covid’ Psyop and part-owns, with ‘innovation charity’ Nesta, the Behavioural Insights Team (BIT) which claims to be independent of government but patently isn’t. The BIT was established in 2010 and its job is to manipulate the psyche of the population to acquiesce to government demands and so much more. It is also known as the ‘Nudge Unit’, a name inspired by the 2009 book by two ultra-Zionists, Cass Sunstein and Richard Thaler, called *Nudge: Improving Decisions About Health, Wealth, and Happiness*. The book, as with the Behavioural Insights Team, seeks to ‘nudge’ behaviour (manipulate it) to make the public follow patterns of action and perception that suit those in authority (the Cult). Sunstein is so skilled at this that he advises the World Health Organization and the UK Behavioural Insights Team and was Administrator of the White House Office of Information and Regulatory Affairs in the Obama administration. Biden appointed him to the Department of Homeland Security – another ultra-Zionist in the fold to oversee new immigration laws which is another policy the Cult wants to control. Sunstein is desperate to silence anyone exposing conspiracies and co-authored a 2008 report on the subject in which suggestions were offered to ban ‘conspiracy theorizing’ or impose ‘some kind of tax, financial or otherwise, on those who disseminate such theories’. I guess a psychiatrist’s chair is out of the question?

Sunstein's mate Richard Thaler, an 'academic affiliate' of the UK Behavioural Insights Team, is a proponent of 'behavioural economics' which is defined as the study of 'the effects of psychological, cognitive, emotional, cultural and social factors on the decisions of individuals and institutions'. Study the effects so they can be manipulated to be what you want them to be. Other leading names in the development of behavioural economics are ultra-Zionists Daniel Kahneman and Robert J. Shiller and they, with Thaler, won the Nobel Memorial Prize in Economic Sciences for their work in this field. The Behavioural Insights Team is operating at the heart of the UK government and has expanded globally through partnerships with several universities including Harvard, Oxford, Cambridge, University College London (UCL) and Pennsylvania. They claim to have 'trained' (reframed) 20,000 civil servants and run more than 750 projects involving 400 randomised controlled trials in dozens of countries' as another version of mind reframers Common Purpose. BIT works from its office in New York with cities and their agencies, as well as other partners, across the United States and Canada – this is a company part-owned by the British government Cabinet Office. An executive order by President Cult-servant Obama established a US Social and Behavioral Sciences Team in 2015. They all have the same reason for being and that's to brainwash the population directly and by brainwashing those in positions of authority.

'Covid' mind game

Another prime aspect of the UK mind-control network is the 'independent' [joke] Scientific Pandemic Insights Group on Behaviours (SPI-B) which 'provides behavioural science advice aimed at anticipating and helping people adhere to interventions that are recommended by medical or epidemiological experts'. That means manipulating public perception and behaviour to do whatever government tells them to do. It's disgusting and if they really want the public to be 'safe' this lot should all be under lock and key. According to the government website SPI-B consists of ‘behavioural scientists, health and social psychologists, anthropologists and historians’ and advises the Whitty-Vallance-led Scientific Advisory Group for Emergencies (SAGE) which in turn advises the government on ‘the science’ (it doesn’t) and ‘Covid’ policy. When politicians say they are being guided by ‘the science’ this is the rabble in each country they are talking about and that ‘science’ is dominated by behaviour manipulators to enforce government fascism through public compliance. The Behaviour Insight Team is headed by psychologist David Solomon Halpern, a visiting professor at King’s College London, and connects with a national and global web of other civilian and military organisations as the Cult moves towards its goal of fusing them into one fascistic whole in every country through its ‘Fusion Doctrine’. The behaviour manipulation network involves, but is not confined to, the Foreign Office; National Security Council; government communications headquarters (GCHQ); MI5; MI6; the Cabinet Office-based Media Monitoring Unit; and the Rapid Response Unit which ‘monitors digital trends to spot emerging issues; including misinformation and disinformation; and identifies the best way to respond’.

There is also the 77th Brigade of the UK military which operates like the notorious Israeli military’s Unit 8200 in manipulating information and discussion on the Internet by posing as members of the public to promote the narrative and discredit those who challenge it. Here we have the military seeking to manipulate *domestic* public opinion while the Nazis in government are fine with that. Conservative Member of Parliament Tobias Ellwood, an advocate of lockdown and control through ‘vaccine passports’, is a Lieutenant Colonel reservist in the 77th Brigade which connects with the military operation jHub, the ‘innovation centre’ for the Ministry of Defence and Strategic Command. jHub has also been involved with the civilian National Health Service (NHS) in ‘symptom tracing’ the population. The NHS is a key part of this mind control network and produced a document in December, 2020, explaining to staff how to use psychological manipulation with different groups and ages to get them to have the DNA-manipulating ‘Covid vaccine’ that's designed to cumulatively rewrite human genetics. The document, called 'Optimising Vaccination Roll Out – Do's and Dont's for all messaging, documents and "communications" in the widest sense', was published by NHS England and the NHS Improvement *Behaviour Change Unit* in partnership with Public Health England and Warwick Business School. I hear the mantra about 'save the NHS' and 'protect the NHS' when we need to scrap the NHS and start again. The current version is far too corrupt, far too anti-human and totally compromised by Cult operatives and their assets. UK government broadcast media censor Ofcom will connect into this web – as will the BBC with its tremendous Ofcom influence – to control what the public see and hear and dictate mass perception. Nuremberg trials must include personnel from all these organisations.

The fear factor

The 'Covid' hoax has led to the creation of the UK Cabinet Office-connected Joint Biosecurity Centre (JBC) which is officially described as providing 'expert advice on pandemics' using its independent [all Cult operations are 'independent'] analytical function to provide real-time analysis about infection outbreaks to identify and respond to outbreaks of Covid-19'. Another role is to advise the government on a response to spikes in infections – 'for example by closing schools or workplaces in local areas where infection levels have risen'. Put another way, promoting the Cult agenda. The Joint Biosecurity Centre is modelled on the Joint Terrorism Analysis Centre which analyses intelligence to set 'terrorism threat levels' and here again you see the fusion of civilian and military operations and intelligence that has led to military intelligence producing documents about 'vaccine hesitancy' and how it can be combated. Domestic civilian matters and opinions should not be the business of the military. The Joint Biosecurity Centre is headed by Tom Hurd, director general of the Office for Security and Counter-Terrorism from the establishment-to-its-fingertips Hurd family. His father is former Foreign Secretary Douglas Hurd. How coincidental that Tom

Hurd went to the elite Eton College and Oxford University with Boris Johnson. Imperial College with its ridiculous computer modeller Neil Ferguson will connect with this gigantic web that will itself interconnect with similar set-ups in other major and not so major countries. Compared with this Cult network the politicians, be they Boris Johnson, Donald Trump or Joe Biden, are bit-part players 'following the science'. The network of psychologists was on the 'Covid' case from the start with the aim of generating maximum fear of the 'virus' to ensure compliance by the population. A government behavioural science group known as SPI-B produced a paper in March, 2020, for discussion by the main government science advisory group known as SAGE. It was headed 'Options for increasing adherence to social distancing measures' and it said the following in a section headed 'Persuasion':

- A substantial number of people still do not feel sufficiently personally threatened; it could be that they are reassured by the low death rate in their demographic group, although levels of concern may be rising. Having a good understanding of the risk has been found to be positively associated with adoption of COVID-19 social distancing measures in Hong Kong.

- The perceived level of personal threat needs to be increased among those who are complacent, using hard-hitting evaluation of options for increasing social distancing emotional messaging. To be effective this must also empower people by making clear the actions they can take to reduce the threat.

- Responsibility to others: There seems to be insufficient understanding of, or feelings of responsibility about, people's role in transmitting the infection to others … Messaging about actions need to be framed positively in terms of protecting oneself and the community, and increase confidence that they will be effective.

- Some people will be more persuaded by appeals to play by the rules, some by duty to the community, and some to personal risk.

> All these different approaches are needed. The messaging also needs to take account of the realities of different people's lives. Messaging needs to take account of the different motivational levers and circumstances of different people.

All this could be achieved the SPI-B psychologists said by *using the media to increase the sense of personal threat* which translates as terrify the shit out of the population, including children, so they all do what we want. That's not happened has it? Those excuses for 'journalists' who wouldn't know journalism if it bit them on the arse (the great majority) have played their crucial part in serving this Cult-government Psyop to enslave their own kids and grandkids. How they live with themselves I have no idea. The psychological war has been underpinned by constant government 'Covid' propaganda in almost every television and radio ad break, plus the Internet and print media, which has pounded out the fear with taxpayers footing the bill for their own programming. The result has been people terrified of a 'virus' that doesn't exist or one with a tiny fatality rate even if you believe it does. People walk down the street and around the shops wearing face-nappies damaging their health and psychology while others report those who refuse to be that naïve to the police who turn up in their own face-nappies. I had a cameraman come to my flat and he was so frightened of 'Covid' he came in wearing a mask and refused to shake my hand in case he caught something. He had – naïveitis – and the thought that he worked in the mainstream media was both depressing and made his behaviour perfectly explainable. The fear which has gripped the minds of so many and frozen them into compliance has been carefully cultivated by these psychologists who are really psychopaths. If lives get destroyed and a lot of young people commit suicide it shows our plan is working. SPI-B then turned to compulsion on the public to comply. 'With adequate preparation, rapid change can be achieved', it said. Some countries had introduced mandatory self-isolation on a wide scale without evidence of major public unrest and a large majority of the UK's population appeared to be supportive of more coercive measures with 64 percent of adults saying they would support putting London under a lockdown (watch the 'polls' which are designed to make people believe that public opinion is in favour or against whatever the subject in hand).

For 'aggressive protective measures' to be effective, the SPI-B paper said, special attention should be devoted to those population groups that are more at risk. Translated from the Orwellian this means making the rest of population feel guilty for not protecting the 'vulnerable' such as old people which the Cult and its agencies were about to kill on an industrial scale with lockdown, lack of treatment and the Gates 'vaccine'. Psychopath psychologists sold their guilt-trip so comprehensively that Los Angeles County Supervisor Hilda Solis reported that children were apologising (from a distance) to their parents and grandparents for bringing 'Covid' into their homes and getting them sick. '… These apologies are just some of the last words that loved ones will ever hear as they die alone,' she said. Gut-wrenchingly Solis then used this childhood tragedy to tell children to stay at home and 'keep your loved ones alive'. Imagine heaping such potentially life-long guilt on a kid when it has absolutely nothing to do with them. These people are deeply disturbed and the psychologists behind this even more so.

Uncivil war – divide and rule

Professional mind-controllers at SPI-B wanted the media to increase a sense of responsibility to others (do as you're told) and promote 'positive messaging' for those actions while in contrast to invoke 'social disapproval' by the unquestioning, obedient, community of anyone with a mind of their own. Again the compliant Goebbels-like media obliged. This is an old, old, trick employed by tyrannies the world over throughout human history. You get the target population to keep the target population in line – *your* line. SPI-B said this could 'play an important role in preventing anti-social behaviour or discouraging failure to enact pro-social behaviour'. For 'anti-social' in the Orwellian parlance of SPI-B see any behaviour that government doesn't approve. SPI-B recommendations said that 'social disapproval' should be accompanied by clear messaging and promotion of strong collective identity – hence the government and celebrity mantra of 'we're all in this together'. Sure we are. The mind doctors have such contempt for their targets that they think some clueless comedian, actor or singer telling them to do what the government wants will be enough to win them over. We have had UK comedian Lenny Henry, actor Michael Caine and singer Elton John wheeled out to serve the propagandists by urging people to have the DNA-manipulating 'Covid' non-'vaccine'. The role of Henry and fellow black celebrities in seeking to coax a 'vaccine' reluctant black community into doing the government's will was especially stomach-turning. An emotion-manipulating script and carefully edited video featuring these black 'celebs' was such an insult to the intelligence of black people and where's the self-respect of those involved selling their souls to a fascist government agenda? Henry said he heard black people's 'legitimate worries and concerns', but people must 'trust the facts' when they were doing exactly that by not having the 'vaccine'. They had to include the obligatory reference to Black Lives Matter with the line … 'Don't let coronavirus cost even more black lives – because we matter'. My god, it was pathetic. 'I know the vaccine is safe and what it does.' How? 'I'm a comedian and it says so in my script.'

SPI-B said social disapproval needed to be carefully managed to avoid victimisation, scapegoating and misdirected criticism, but they knew that their 'recommendations' would lead to exactly that and the media were specifically used to stir-up the divide-and-conquer hostility. Those who conform like good little baa, baas, are praised while those who have seen through the tidal wave of lies are 'Covidiots'. The awake have been abused by the fast asleep for not conforming to fascism and impositions that the awake know are designed to endanger their health, dehumanise them, and tear asunder the very fabric of human society. We have had the curtain-twitchers and morons reporting neighbours and others to the face-nappied police for breaking 'Covid rules' with fascist police delighting in posting links and phone numbers where this could be done. The Cult cannot impose its will without a compliant police and military or a compliant population willing to play their part in enslaving themselves and their kids. The words of a pastor in Nazi Germany are so appropriate today:

> First they came for the socialists and I did not speak out because I was not a socialist.
>
> Then they came for the trade unionists and I did not speak out because I was not a trade unionist.
>
> Then they came for the Jews and I did not speak out because I was not a Jew.
>
> Then they came for me and there was no one left to speak for me.

Those who don't learn from history are destined to repeat it and so many are.

'Covid' rules: Rewiring the mind

With the background laid out to this gigantic national and global web of psychological manipulation we can put 'Covid' rules into a clear and sinister perspective. Forget the claims about protecting health. 'Covid' rules are about dismantling the human mind, breaking the human spirit, destroying self-respect, and then putting Humpty Dumpty together again as a servile, submissive slave. Social isolation through lockdown and distancing have devastating effects on the human psyche as the psychological psychopaths well know and that's the real reason for them. Humans need contact with each other, discourse, closeness and touch, or they eventually, and literarily, go crazy. Masks, which I will address at some length, fundamentally add to the effects of isolation and the Cult agenda to dehumanise and de-individualise the population. To do this while knowing – in fact *seeking* – this outcome is the very epitome of evil and psychologists involved in this *are* the epitome of evil. They must like all the rest of the Cult demons and their assets stand trial for crimes against humanity on a scale that defies the imagination. Psychopaths in uniform use isolation to break enemy troops and agents and make them subservient and submissive to tell what they know. The technique is rightly considered a form of torture and torture is most certainly what has been imposed on the human population.

Clinically-insane American psychologist Harry Harlow became famous for his isolation experiments in the 1950s in which he separated baby monkeys from their mothers and imprisoned them for months on end in a metal container or 'pit of despair'. They soon began to show mental distress and depression as any idiot could have predicted. Harlow put other monkeys in steel chambers for three, six or twelve months while denying them any contact with animals or humans. He said that the effects of total social isolation for six months were 'so devastating and debilitating that we had assumed initially that twelve months of isolation would not produce any additional decrement'; but twelve months of isolation 'almost obliterated the animals socially'. This is what the Cult and its psychopaths are doing to you and your children. Even monkeys in partial isolation in which they were not allowed to form relationships with other monkeys became 'aggressive and hostile, not only to others, but also towards their own bodies'. We have seen this in the young as a consequence of lockdown. UK government psychopaths launched a public relations campaign telling people not to hug each other even after they received the 'Covid-19 vaccine' which we were told with more lies would allow a return to 'normal life'. A government source told *The Telegraph*: 'It will be along the lines that it is great that you have been vaccinated, but if you are going to visit your family and hug your grandchildren there is a chance you are going to infect people you love.' The source was apparently speaking from a secure psychiatric facility. Janet Lord, director of Birmingham University's Institute of Inflammation and Ageing, said that parents and grandparents should avoid hugging their children. Well, how can I put it, Ms Lord? Fuck off. Yep, that'll do.

Destroying the kids – where are the parents?

Observe what has happened to people enslaved and isolated by lockdown as suicide and self-harm has soared worldwide, particularly among the young denied the freedom to associate with their friends. A study of 49,000 people in English-speaking countries concluded that almost half of young adults are at clinical risk of mental health disorders. A national survey in America of 1,000 currently enrolled high school and college students found that 5 percent reported attempting suicide during the pandemic. Data from the US CDC's National Syndromic Surveillance Program from January 1st to October 17th, 2020, revealed a *31 percent* increase in mental health issues among adolescents aged 12 to 17 compared with 2019. The CDC reported that America in general suffered the biggest drop in life expectancy since World War Two as it fell by a year in the first half of 2020 as a result of 'deaths of despair' – overdoses and suicides. Deaths of despair have leapt by more than 20 percent during lockdown and include the highest number of fatal overdoses ever recorded in a single year – 81,000. Internet addiction is another consequence of being isolated at home which lowers interest in physical activities as kids fall into inertia and what's the point? Children and young people are losing hope and giving up on life, sometimes literally. A 14-year-old boy killed himself in Maryland because he had 'given up' when his school district didn't reopen; an 11-year-old boy shot himself during a zoom class; a teenager in Maine succumbed to the isolation of the 'pandemic' when he ended his life after experiencing a disrupted senior year at school. Children as young as nine have taken their life and all these stories can be repeated around the world. Careers are being destroyed before they start and that includes those in sport in which promising youngsters have not been able to take part. The plan of the psycho-psychologists is working all right. Researchers at Cambridge University found that lockdowns cause significant harm to children's mental health. Their study was published in the *Archives of Disease in Childhood*, and followed 168 children aged between 7 and 11. The researchers concluded:

> During the UK lockdown, children's depression symptoms have increased substantially, relative to before lockdown. The scale of this effect has direct relevance for the continuation of different elements of lockdown policy, such as complete or partial school closures …

> … Specifically, we observed a statistically significant increase in ratings of depression, with a medium-to-large effect size. Our findings emphasise the need to incorporate the potential impact of lockdown on child mental health in planning the ongoing response to the global pandemic and the recovery from it.

Not a chance when the Cult's psycho-psychologists were getting exactly what they wanted. The UK's Royal College of Paediatrics and Child Health has urged parents to look for signs of eating disorders in children and young people after a three to four fold increase. Specialists say the 'pandemic' is a major reason behind the rise. You don't say. The College said isolation from friends during school closures, exam cancellations, loss of extra-curricular activities like sport, and an increased use of social media were all contributory factors along with fears about the virus (psycho-psychologists again), family finances, and students being forced to quarantine. Doctors said young people were becoming severely ill by the time they were seen with 'Covid' regulations reducing face-to-face consultations. Nor is it only the young that have been devastated by the psychopaths. Like all bullies and cowards the Cult is targeting the young, elderly, weak and infirm. A typical story was told by a British lady called Lynn Parker who was not allowed to visit her husband in 2020 for the last ten and half months of his life 'when he needed me most' between March 20th and when he died on December 19th. This vacates the criminal and enters the territory of evil. The emotional impact on the immune system alone is immense as are the number of people of all ages worldwide who have died as a result of Cult-demanded, Gates-demanded, lockdowns.

Isolation is torture

The experience of imposing solitary confinement on millions of prisoners around the world has shown how a large percentage become 'actively psychotic and/or acutely suicidal'. Social isolation has been found to trigger 'a specific psychiatric syndrome, characterized by hallucinations; panic attacks; overt paranoia; diminished impulse control; hypersensitivity to external stimuli; and difficulties with thinking, concentration and memory'. Juan Mendez, a United Nations rapporteur (investigator), said that isolation is a form of torture. Research has shown that even after isolation prisoners find it far more difficult to make social connections and I remember chatting to a shop assistant after one lockdown who told me that when her young son met another child again he had no idea how to act or what to do. Hannah Flanagan, Director of Emergency Services at Journey Mental Health Center in Dane County, Wisconsin, said: 'The specificity about Covid social distancing and isolation that we've come across as contributing factors to the suicides are really new to us this year.' But they are not new to those that devised them. They are getting the effect they want as the population is psychologically dismantled to be rebuilt in a totally different way. Children and the young are particularly targeted. They will be the adults when the full-on fascist AI-controlled technocracy is planned to be imposed and they are being prepared to meekly submit. At the same time older people who still have a memory of what life was like before – and how fascist the new normal really is – are being deleted. You are going to see efforts to turn the young against the old to support this geriatric genocide. Hannah Flanagan said the big increase in suicide in her county proved that social isolation is not only harmful, but deadly. Studies have shown that isolation from others is one of the main risk factors in suicide and even more so with women. Warnings that lockdown could create a 'perfect storm' for suicide were ignored. After all this was one of the *reasons* for lockdown. Suicide, however, is only the most extreme of isolation consequences. There are many others. Dr Dhruv Khullar, assistant professor of healthcare policy at Weill Cornell Medical College, said in a *New York Times* article in 2016 long before the fake 'pandemic':

> A wave of new research suggests social separation is bad for us. Individuals with less social connection have disrupted sleep patterns, altered immune systems, more inflammation and higher levels of stress hormones. One recent study found that isolation increases the risk of heart disease by 29 percent and stroke by 32 percent. Another analysis that pooled data from 70 studies and 3.4 million people found that socially isolated individuals had a 30 percent higher risk of dying in the next seven years, and that this effect was largest in middle age.

> Loneliness can accelerate cognitive decline in older adults, and isolated individuals are twice as likely to die prematurely as those with more robust social interactions. These effects start early: Socially isolated children have significantly poorer health 20 years later, even after controlling for other factors. All told, loneliness is as important a risk factor for early death as obesity and smoking.

There you have proof from that one article alone four years before 2020 that those who have enforced lockdown, social distancing and isolation knew what the effect would be and that is even more so with professional psychologists that have been driving the policy across the globe. We can go back even further to the years 2000 and 2003 and the start of a major study on the effects of isolation on health by Dr Janine Gronewold and Professor Dirk M. Hermann at the University Hospital in Essen, Germany, who analysed data on 4,316 people with an average age of 59 who were recruited for the long-term research project. They found that socially isolated people are more than 40 percent more likely to have a heart attack, stroke, or other major cardiovascular event and nearly 50 percent more likely to die from any cause. Given the financial Armageddon unleashed by lockdown we should note that the study found a relationship between increased cardiovascular risk and lack of financial support. After excluding other factors social isolation was still connected to a 44 percent increased risk of cardiovascular problems and a 47 percent increased risk of death by any cause. Lack of financial support was associated with a 30 percent increase in the risk of cardiovascular health events. Dr Gronewold said it had been known for some time that feeling lonely or lacking contact with close friends and family can have an impact on physical health and the study had shown that having strong social relationships is of high importance for heart health. Gronewold said they didn't understand yet why people who are socially isolated have such poor health outcomes, but this was obviously a worrying finding, particularly during these times of prolonged social distancing. Well, it can be explained on many levels. You only have to identify the point in the body where people feel loneliness and missing people they are parted from – it's in the centre of the chest where they feel the ache of loneliness and the ache of missing people. 'My heart aches for you' … 'My heart aches for some company.' I will explain this more in the chapter Escaping Wetiko, but when you realise that the body is the mind – they are expressions of each other – the reason why state of the mind dictates state of the body becomes clear.

American psychologist Ranjit Powar was highlighting the effects of lockdown isolation as early as April, 2020. She said humans have evolved to be social creatures and are wired to live in interactive groups. Being isolated from family, friends and colleagues could be unbalancing and traumatic for most people and could result in short or even long-term psychological and physical health problems. An increase in levels of anxiety, aggression, depression, forgetfulness and hallucinations were possible psychological effects of isolation. 'Mental conditions may be precipitated for those with underlying pre-existing susceptibilities and show up in many others without any pre-condition.' Powar said personal relationships helped us cope with stress and if we lost this outlet for letting off steam the result can be a big emotional void which, for an average person, was difficult to deal with. 'Just a few days of isolation can cause increased levels of anxiety and depression' – so what the hell has been the effect on the global population of *18 months* of this at the time of writing? Powar said: 'Add to it the looming threat of a dreadful disease being repeatedly hammered in through the media and you have a recipe for many shades of mental and physical distress.' For those with a house and a garden it is easy to forget that billions have had to endure lockdown isolation in tiny overcrowded flats and apartments with nowhere to go outside. The psychological and physical consequences of this are unimaginable and with lunatic and abusive partners and parents the consequences have led to tremendous increases in domestic and child abuse and alcoholism as people seek to shut out the horror. Ranjit Powar said:

> Staying in a confined space with family is not all a rosy picture for everyone. It can be extremely oppressive and claustrophobic for large low-income families huddled together in small single-room houses. Children here are not lucky enough to have many board/electronic games or books to keep them occupied.

> Add to it the deep insecurity of running out of funds for food and basic necessities. On the other hand, there are people with dysfunctional family dynamics, such as domineering, abusive or alcoholic partners, siblings or parents which makes staying home a period of trial. Incidence of suicide and physical abuse against women has shown a worldwide increase. Heightened anxiety and depression also affect a person's immune system, making them more susceptible to illness.

To think that Powar's article was published on April 11th, 2020.

Six-feet fantasy

Social (unsocial) distancing demanded that people stay six feet or two metres apart. UK government advisor Robert Dingwall from the New and Emerging Respiratory Virus Threats Advisory Group said in a radio interview that the two-metre rule was 'conjured up out of nowhere' and was not based on science. No, it was not based on *medical* science, but it didn't come out of nowhere. The distance related to *psychological* science. Six feet/two metres was adopted in many countries and we were told by people like the criminal Anthony Fauci and his ilk that it was founded on science. Many schools could not reopen because they did not have the space for six-feet distancing. Then in March, 2021, after a year of six-feet 'science', a study published in the *Journal of Infectious Diseases* involving more than 500,000 students and almost 100,000 staff over 16 weeks revealed no significant difference in 'Covid' cases between six feet and three feet and Fauci changed his tune. Now three feet was okay. There is no difference between six feet and three *inches* when there is no 'virus' and they got away with six feet for psychological reasons for as long as they could. I hear journalists and others talk about 'unintended consequences' of lockdown. They are not *unintended* at all; they have been coldly-calculated for a specific outcome of human control and that's why super-psychopaths like Gates have called for them so vehemently. Super-psychopath psychologists have demanded them and psychopathic or clueless, spineless, politicians have gone along with them by 'following the science'. But it's not science at all. 'Science' is not what is; it's only what people can be manipulated to believe it is. The whole 'Covid' catastrophe is founded on mind control. Three word or three statement mantras issued by the UK government are a well-known mind control technique and so we've had 'Stay home/protect the NHS/save lives', 'Stay alert/control the virus/save lives' and 'hands/face/space'. One of the most vocal proponents of extreme 'Covid' rules in the UK has been Professor Susan Michie, a member of the British Communist Party, who is not a medical professional. Michie is the director of the Centre for Behaviour Change at University College London. She is a *behavioural psychologist* and another filthy rich 'Marxist' who praised China's draconian lockdown. She was known by fellow students at Oxford University as 'Stalin's nanny' for her extreme Marxism. Michie is an influential member of the UK government's Scientific Advisory Group for Emergencies (SAGE) and behavioural manipulation groups which have dominated 'Covid' policy. She is a consultant adviser to the World Health Organization on 'Covid-19' and behaviour. Why the hell are lockdowns anything to do with her when they are claimed to be about health? Why does a behavioural psychologist from a group charged with changing the behaviour of the public want lockdown, human isolation and mandatory masks? Does that question really need an answer? Michie *absolutely* has to explain herself before a Nuremberg court when humanity takes back its world again and even more so when you see the consequences of masks that she demands are compulsory. This is a Michie classic:

> The benefits of getting primary school children to wear masks is that regardless of what little degree of transmission is occurring in those age groups it could help normalise the practice. Young children wearing masks may be more likely to get their families to accept masks.

Those words alone should carry a prison sentence when you ponder on the callous disregard for children involved and what a statement it makes about the mind and motivations of Susan Michie. What a lovely lady and what she said there encapsulates the mentality of the psychopaths behind the 'Covid' horror. Let us compare what Michie said with a countrywide study in Germany published at researchsquare.com involving 25,000 school children and 17,854 health complaints submitted by parents. Researchers found that masks are harming children physically, psychologically, and behaviourally with 24 health issues associated with mask wearing. They include: shortness of breath (29.7%); dizziness (26.4%); increased headaches (53%); difficulty concentrating (50%); drowsiness or fatigue (37%); and malaise (42%). Nearly a third of children experienced more sleep issues than before and a quarter developed new fears. Researchers found health issues and other impairments in 68 percent of masked children covering their faces for an average of 4.5 hours a day. Hundreds of those taking part experienced accelerated respiration, tightness in the chest, weakness, and short-term impairment of consciousness. A reminder of what Michie said again:

> The benefits of getting primary school children to wear masks is that regardless of what little degree of transmission is occurring in those age groups it could help normalise the practice. Young children wearing masks may be more likely to get their families to accept masks.

Psychopaths in government and psychology now have children and young people – plus all the adults – wearing masks for hours on end while clueless teachers impose the will of the psychopaths on the young they should be protecting. What the hell are parents doing?

Cult lab rats

We have some schools already imposing on students microchipped buzzers that activate when they get ‘too close’ to their pals in the way they do with lab rats. How apt. To the Cult and its brain-dead servants our children *are* lab rats being conditioned to be unquestioning, dehumanised slaves for the rest of their lives. Children and young people are being weaned and frightened away from the most natural human instincts including closeness and touch. I have tracked in the books over the years how schools were banning pupils from greeting each other with a hug and the whole Cult-induced Me Too movement has terrified men and boys from a relaxed and natural interaction with female friends and work colleagues to the point where many men try never to be in a room alone with a woman that's not their partner. Airhead celebrities have as always played their virtue-signalling part in making this happen with their gross exaggeration. For every monster like Harvey Weinstein there are at least tens of thousands of men that don't treat women like that; but everyone must be branded the same and policy changed for them as well as the monster. I am going to be using the word 'dehumanise' many times in this chapter because that is what the Cult is seeking to do and it goes very deep as we shall see. Don't let them kid you that social distancing is planned to end one day. That's not the idea. We are seeing more governments and companies funding and producing wearable gadgets to keep people apart and they would not be doing that if this was meant to be short-term. A tech start-up company backed by GCHQ, the British Intelligence and military surveillance headquarters, has created a social distancing wrist sensor that alerts people when they get too close to others. The CIA has also supported tech companies developing similar devices. The wearable sensor was developed by Tended, one of a number of start-up companies supported by GCHQ (see the CIA and DARPA). The device can be worn on the wrist or as a tag on the waistband and will vibrate whenever someone wearing the device breaches social distancing and gets anywhere near natural human contact. The company had a lucky break in that it was developing a distancing sensor when the 'Covid' hoax arrived which immediately provided a potentially enormous market. How fortunate. The government in big-time Cult-controlled Ontario in Canada is investing $2.5 million in wearable contact tracing technology that 'will alert users if they may have been exposed to the Covid-19 in the workplace and will beep or vibrate if they are within six feet of another person'. Facedrive Inc., the technology company behind this, was founded in 2016 with funding from the Ontario Together Fund and obviously they, too, had a prophet on the board of directors. The human surveillance and control technology is called TraceSCAN and would be worn by the human cyborgs in places such as airports, workplaces, construction sites, care homes and … *schools*.

I emphasise schools with children and young people the prime targets. You know what is planned for society as a whole if you keep your eyes on the schools. They have always been places where the state program the next generation of slaves to be its compliant worker-ants – or Woker-ants these days; but in the mist of the 'Covid' madness they have been transformed into mind laboratories on a scale never seen before. Teachers and head teachers are just as programmed as the kids – often more so. Children are kept apart from human interaction by walk lanes, classroom distancing, staggered meal times, masks, and the rolling-out of buzzer systems. Schools are now physically laid out as a laboratory maze for lab-rats. Lunatics at a school in Anchorage, Alaska, who should be prosecuted for child abuse, took away desks and forced children to kneel (know your place) on a mat for five hours a day while wearing a mask and using their chairs as a desk. How this was supposed to impact on a 'virus' only these clinically insane people can tell you and even then it would be clap-trap. The school banned recess (interaction), art classes (creativity), and physical exercise (getting body and mind moving out of inertia). Everyone behind this outrage should be in jail or better still a mental institution. The behavioural manipulators are all for this dystopian approach to schools. Professor Susan Michie, the mind-doctor and British Communist Party member, said it was wrong to say that schools were safe. They had to be made so by 'distancing', masks and ventilation (sitting all day in the cold). I must ask this lady round for dinner on a night I know I am going to be out and not back for weeks. She probably wouldn't be able to make it, anyway, with all the visits to her own psychologist she must have block-booked.

Masking identity

I know how shocking it must be for you that a behaviour manipulator like Michie wants everyone to wear masks which have long been a feature of mind-control programs like the infamous MKUltra in the United States, but, there we are. We live and learn. I spent many years from 1996 to right across the millennium researching mind control in detail on both sides of the Atlantic and elsewhere. I met a large number of mind-control survivors and many had been held captive in body and mind by MKUltra. MK stands for mind-control, but employs the German spelling in deference to the Nazis spirited out of Germany at the end of World War Two by Operation Paperclip in which the US authorities, with help from the Vatican, transported Nazi mind-controllers and engineers to America to continue their work. Many of them were behind the creation of NASA and they included Nazi scientist and SS officer Wernher von Braun who swapped designing V-2 rockets to bombard London with designing the Saturn V rockets that powered the NASA moon programme's Apollo craft. I think I may have mentioned that the Cult has no borders. Among Paperclip escapees was Josef Mengele, the Angel of Death in the Nazi concentration camps where he conducted mind and genetic experiments on children often using twins to provide a control twin to measure the impact of his 'work' on the other. If you want to observe the Cult mentality in all its extremes of evil then look into the life of Mengele. I have met many people who suffered mercilessly under Mengele in the United States where he operated under the name Dr Greene and became a stalwart of MKUltra programming and torture. Among his locations was the underground facility in the Mojave Desert in California called the China Lake Naval Weapons Station which is almost entirely below the surface. My books *The Biggest Secret*, *Children of the Matrix* and *The Perception Deception* have the detailed background to MKUltra.

The best-known MKUltra survivor is American Cathy O'Brien. I first met her and her late partner Mark Phillips at a conference in Colorado in 1996. Mark helped her escape and deprogram from decades of captivity in an offshoot of MKUltra known as Project Monarch in which 'sex slaves' were provided for the rich and famous including Father George Bush, Dick Cheney and the Clintons. Read Cathy and Mark's book *Trance-Formation of America* and if you are new to this you will be shocked to the core. I read it in 1996 shortly before, with the usual synchronicity of my life, I found myself given a book table at the conference right next to hers. MKUltra never ended despite being very publicly exposed (only a small part of it) in the 1970s and continues in other guises. I am still in touch with Cathy. She contacted me during 2020 after masks became compulsory in many countries to tell me how they were used as part of MKUltra programming. I had been observing 'Covid regulations' and the relationship between authority and public for months. I saw techniques that I knew were employed on individuals in MKUltra being used on the global population. I had read many books and manuals on mind control including one called *Silent Weapons for Quiet Wars* which came to light in the 1980s and was a guide on how to perceptually program on a mass scale. 'Silent Weapons' refers to mind-control. I remembered a line from the manual as governments, medical authorities and law enforcement agencies have so obviously talked to – or rather at – the adult population since the 'Covid' hoax began as if they are children. The document said:

> If a person is spoken to by a T.V. advertiser as if he were a twelve-year-old, then, due to suggestibility, he will, with a certain probability, respond or react to that suggestion with the uncritical response of a twelve-year-old and will reach in to his economic reservoir and deliver its energy to buy that product on impulse when he passes it in the store.

That's why authority has spoken to adults like children since all this began.

Why did Michael Jackson wear masks?

Every aspect of the 'Covid' narrative has mind-control as its central theme. Cathy O'Brien wrote an article for davidicke.com about the connection between masks and mind control. Her daughter Kelly who I first met in the 1990s was born while Cathy was still held captive in MKUltra. Kelly was forced to wear a mask as part of her programming from the age of *two* to dehumanise her, target her sense of individuality and reduce the amount of oxygen her brain and body received. *Bingo*. This is the real reason for compulsory masks, why they have been enforced en masse, and why they seek to increase the number they demand you wear. First one, then two, with one disgraceful alleged 'doctor' recommending four which is nothing less than a death sentence. Where and how often they must be worn is being expanded for the purpose of mass mind control and damaging respiratory health which they can call 'Covid-19'. Canada's government headed by the man-child Justin Trudeau, says it's fine for children of two and older to wear masks. An insane 'study' in Italy involving just 47 children concluded there was no problem for babies as young as *four months* wearing them. Even after people were 'vaccinated' they were still told to wear masks by the criminal that is Anthony Fauci. Cathy wrote that mandating masks is allowing the authorities literally to control the air we breathe which is what was done in MKUltra. You might recall how the singer Michael Jackson wore masks and there is a reason for that. He was subjected to MKUltra mind control through Project Monarch and his psyche was scrambled by these simpletons. Cathy wrote:

> In MKUltra Project Monarch mind control, Michael Jackson had to wear a mask to silence his voice so he could not reach out for help. Remember how he developed that whisper voice when he wasn't singing? Masks control the mind from the outside in, like the redefining of words is doing. By controlling what we can and cannot say for fear of being labeled racist or beaten, for example, it ultimately controls thought that drives our words and ultimately actions (or lack thereof).
>
> Likewise, a mask muffles our speech so that we are not heard, which controls voice … words … mind. This is Mind Control. Masks are an obvious mind control device, and I am disturbed so many people are complying on a global scale. Masks depersonalize while making a person feel as though they have no voice. It is a barrier to others. People who would never choose to comply but are forced to wear a mask in order to keep their job, and ultimately their family fed, are compromised. They often feel shame and are subdued. People have stopped talking with each other while media controls the narrative.

The 'no voice' theme has often become literal with train passengers told not to speak to each other in case they pass on the 'virus', singing banned for the same reason and bonkers California officials telling people riding roller coasters that they cannot shout and scream. Cathy said she heard every day from healed MKUltra survivors who cannot wear a mask without flashing back on ways their breathing was controlled – 'from ball gags and penises to water boarding'. She said that through the years when she saw images of people in China wearing masks 'due to pollution' that it was really to control their oxygen levels. 'I knew it was as much of a population control mechanism of depersonalisation as are burkas', she said. Masks are another Chinese communist/fascist method of control that has been swept across the West as the West becomes China at lightning speed since we entered 2020.

Mask-19

There are other reasons for mandatory masks and these include destroying respiratory health to call it 'Covid-19' and stunting brain development of children and the young. Dr Margarite Griesz-Brisson MD, PhD, is a Consultant Neurologist and Neurophysiologist and the Founder and Medical Director of the London Neurology and Pain Clinic. Her CV goes down the street and round the corner. She is clearly someone who cares about people and won't parrot the propaganda. Griesz-Brisson has a PhD in pharmacology, with special interest in neurotoxicology, environmental medicine, neuroregeneration and neuroplasticity (the way the brain can change in the light of information received). She went public in October, 2020, with a passionate warning about the effects of mask-wearing laws:

> The reinhalation of our exhaled air will without a doubt create oxygen deficiency and a flooding of carbon dioxide. We know that the human brain is very sensitive to oxygen deprivation. There are nerve cells for example in the hippocampus that can't be longer than 3 minutes without oxygen – they cannot survive. The acute warning symptoms are headaches, drowsiness, dizziness, issues in concentration, slowing down of reaction time – reactions of the cognitive system.

Oh, I know, let's tell bus, truck and taxi drivers to wear them and people working machinery. How about pilots, doctors and police? Griesz-Brisson makes the important point that while the symptoms she mentions may fade as the body readjusts this does not alter the fact that people continue to operate in oxygen deficit with long list of potential consequences. She said it was well known that neurodegenerative diseases take years or decades to develop. 'If today you forget your phone number, the breakdown in your brain would have already started 20 or 30 years ago.' She said degenerative processes in your brain are getting amplified as your oxygen deprivation continues through wearing a mask. Nerve cells in the brain are unable to divide themselves normally in these circumstances and lost nerve cells will no longer be regenerated. 'What is gone is gone.' Now consider that people like shop workers and *schoolchildren* are wearing masks for hours every day. What in the name of sanity is going to be happening to them? 'I do not wear a mask, I need my brain to think', Griesz-Brisson said, 'I want to have a clear head when I deal with my patients and not be in a carbon dioxide-induced anaesthesia'. If you are told to wear a mask anywhere ask the organisation, police, store, whatever, for their risk assessment on the dangers and negative effects on mind and body of enforcing mask-wearing. They won't have one because it has never been done not even by government. All of them must be subject to class-action lawsuits as the consequences come to light. They don't do mask risk assessments for an obvious reason. They know what the conclusions would be and independent scientific studies that *have* been done tell a horror story of consequences.

'Masks are criminal'

Dr Griesz-Brisson said that for children and adolescents, masks are an absolute no-no. They had an extremely active and adaptive immune system and their brain was incredibly active with so much to learn. 'The child's brain, or the youth's brain, is thirsting for oxygen.' The more metabolically active an organ was, the more oxygen it required; and in children and adolescents every organ was metabolically active. Griesz-Brisson said that to deprive a child's or adolescent's brain of oxygen, or to restrict it in any way, was not only dangerous to their health, it was absolutely criminal. 'Oxygen deficiency inhibits the development of the brain, and the damage that has taken place as a result CANNOT be reversed.' Mind manipulators of MKUltra put masks on two-year-olds they wanted to neurologically rewire and you can see why. Griesz-Brisson said a child needs the brain to learn and the brain needs oxygen to function. 'We don't need a clinical study for that. This is simple, indisputable physiology.' Consciously and purposely induced oxygen deficiency was an absolutely deliberate health hazard, and an absolute medical contraindication which means that 'this drug, this therapy, this method or measure should not be used, and is not allowed to be used'. To coerce an entire population to use an absolute medical contraindication by force, she said, there had to be definite and serious reasons and the reasons must be presented to competent interdisciplinary and independent bodies to be verified and authorised. She had this warning of the consequences that were coming if mask wearing continued:

> When, in ten years, dementia is going to increase exponentially, and the younger generations couldn't reach their god-given potential, it won't help to say 'we didn't need the masks'. I know how damaging oxygen deprivation is for the brain, cardiologists know how damaging it is for the heart, pulmonologists know how damaging it is for the lungs. Oxygen deprivation damages every single organ. Where are our health departments, our health insurance, our medical associations? It would have been their duty to be vehemently against the lockdown and to stop it and stop it from the very beginning.
>
> Why do the medical boards issue punishments to doctors who give people exemptions? Does the person or the doctor seriously have to prove that oxygen deprivation harms people? What kind of medicine are our doctors and medical associations representing? Who is responsible for this crime? The ones who want to enforce it? The ones who let it happen and play along, or the ones who don't prevent it?

All of the organisations and people she mentions there either answer directly to the Cult or do whatever hierarchical levels above them tell them to do. The outcome of both is the same. 'It's not about masks, it's not about viruses, it's certainly not about your health', Griesz-Brisson said. 'It is about much, much more. I am not participating. I am not afraid.' They were taking our air to breathe and there was no unfounded medical exemption from face masks. Oxygen deprivation was dangerous for every single brain. It had to be the free decision of every human being whether they want to wear a mask that was absolutely ineffective to protect themselves from a virus. She ended by rightly identifying where the responsibility lies for all this:

> The imperative of the hour is personal responsibility. We are responsible for what we think, not the media. We are responsible for what we do, not our superiors. We are responsible for our health, not the World Health Organization. And we are responsible for what happens in our country, not the government.

Halle-bloody-lujah.

But surgeons wear masks, right?

Independent studies of mask-wearing have produced a long list of reports detailing mental, emotional and physical dangers. What a definition of insanity to see police officers imposing mask-wearing on the public which will cumulatively damage their health while the police themselves wear masks that will cumulatively damage *their* health. It's utter madness and both public and police do this because 'the government says so' – yes a government of brain-donor idiots like UK Health Secretary Matt Hancock reading the 'follow the science' scripts of psychopathic, lunatic psychologists. The response you get from Stockholm syndrome sufferers defending the very authorities that are destroying them and their families is that 'surgeons wear masks'. This is considered the game, set and match that they must work and don't cause oxygen deficit. Well, actually, scientific studies have shown that they *do* and oxygen levels are monitored in operating theatres to compensate. Surgeons wear masks to stop spittle and such like dropping into open wounds – not to stop 'viral particles' which are so miniscule they can only be seen through an electron microscope. Holes in the masks are significantly bigger than 'viral particles' and if you sneeze or cough they will breach the mask. I watched an incredibly disingenuous 'experiment' that claimed to prove that masks work in catching 'virus' material from the mouth and nose. They did this with a slow motion camera and the mask did block big stuff which stayed inside the mask and against the face to be breathed in or cause infections on the face as we have seen with many children. ‘Viral particles’, however, would never have been picked up by the camera as they came through the mask when they are far too small to be seen. The ‘experiment’ was therefore disingenuous *and* useless.

Studies have concluded that wearing masks in operating theatres (and thus elsewhere) make no difference to preventing infection while the opposite is true with toxic shite building up in the mask and this had led to an explosion in tooth decay and gum disease dubbed by dentists ‘mask mouth’. You might have seen the Internet video of a furious American doctor urging people to take off their masks after a four-year-old patient had been rushed to hospital the night before and nearly died with a lung infection that doctors sourced to mask wearing. A study in the journal *Cancer Discovery* found that inhalation of harmful microbes can contribute to advanced stage lung cancer in adults and long-term use of masks can help breed dangerous pathogens. Microbiologists have said frequent mask wearing creates a moist environment in which microbes can grow and proliferate before entering the lungs. The Canadian Agency for Drugs and Technologies in Health, or CADTH, a Canadian national organisation that provides research and analysis to healthcare decision-makers, said this as long ago as 2013 in a report entitled ‘Use of Surgical Masks in the Operating Room: A Review of the Clinical Effectiveness and Guidelines’. It said:

- No evidence was found to support the use of surgical face masks to reduce the frequency of surgical site infections
- No evidence was found on the effectiveness of wearing surgical face masks to protect staff from infectious material in the operating room.
- Guidelines recommend the use of surgical face masks by staff in the operating room to protect both operating room staff and patients (despite the lack of evidence).

We were told that the world could go back to 'normal' with the arrival of the 'vaccines'. When they came, fraudulent as they are, the story changed as I knew that it would. We are in the midst of transforming 'normal', not going back to it. Mary Ramsay, head of immunisation at Public Health England, echoed the words of US criminal Anthony Fauci who said masks and other regulations must stay no matter if people are vaccinated. The Fauci idiot continued to wear two masks – different colours so both could be clearly seen – after he *claimed* to have been vaccinated. Senator Rand Paul told Fauci in one exchange that his double-masks were 'theatre' and he was right. It's all theatre. Mary Ramsay back-tracked on the vaccine-return-to-normal theme when she said the public may need to wear masks and social-distance for years despite the jabs. 'People have got used to those lower-level restrictions now, and [they] can live with them', she said telling us what the idea has been all along. 'The vaccine does not give you a pass, even if you have had it, you must continue to follow all the guidelines' said a Public Health England statement which reneged on what we had been told before and made having the 'vaccine' irrelevant to 'normality' even by the official story. Spain's fascist government trumped everyone by passing a law mandating the wearing of masks on the beach and even when swimming in the sea. The move would have devastated what's left of the Spanish tourist industry, posed potential breathing dangers to swimmers and had Northern European sunbathers walking around with their forehead brown and the rest of their face white as a sheet. The ruling was so crazy that it had to be retracted after pressure from public and tourist industry, but it confirmed where the Cult wants to go with masks and how clinically insane authority has become. The determination to make masks permanent and hide the serious dangers to body and mind can be seen in the censorship of scientist Professor Denis Rancourt by Bill Gates-funded academic publishing website ResearchGate over his papers exposing the dangers and uselessness of masks. Rancourt said:

> ResearchGate today has permanently locked my account, which I have had since 2015. Their reasons graphically show the nature of their attack against democracy, and their corruption of

science … By their obscene non-logic, a scientific review of science articles reporting on harms caused by face masks has a 'potential to cause harm'. No criticism of the psychological device (face masks) is tolerated, if the said criticism shows potential to influence public policy.

This is what happens in a fascist world.

Where are the 'greens' (again)?

Other dangers of wearing masks especially regularly relate to the inhalation of minute plastic fibres into the lungs and the deluge of discarded masks in the environment and oceans. Estimates predicted that more than 1.5 billion disposable masks will end up in the world's oceans every year polluting the water with tons of plastic and endangering marine wildlife. Studies project that humans are using 129 billion face masks each month worldwide – about three million a minute. Most are disposable and made from plastic, non-biodegradable microfibers that break down into smaller plastic particles that become widespread in ecosystems. They are littering cities, clogging sewage channels and turning up in bodies of water. I have written in other books about the immense amounts of microplastics from endless sources now being absorbed into the body. Rolf Halden, director of the Arizona State University (ASU) Biodesign Center for Environmental Health Engineering, was the senior researcher in a 2020 study that analysed 47 human tissue samples and found microplastics in all of them. 'We have detected these chemicals of plastics in every single organ that we have investigated', he said. I wrote in *The Answer* about the world being deluged with microplastics. A study by the Worldwide Fund for Nature (WWF) found that people are consuming on average every week some 2,000 tiny pieces of plastic mostly through water and also through marine life and the air. Every year humans are ingesting enough microplastics to fill a heaped dinner plate and in a life-time of 79 years it is enough to fill two large waste bins. Marco Lambertini, WWF International director general said: 'Not only are plastics polluting our oceans and waterways and killing marine life – it's in all of us and we can't escape consuming plastics,' American geologists found tiny plastic fibres, beads and shards in rainwater samples collected from the remote slopes of the Rocky Mountain National Park near Denver, Colorado. Their report was headed: 'It is raining plastic.' Rachel Adams, senior lecturer in Biomedical Science at Cardiff Metropolitan University, said that among health consequences are internal inflammation and immune responses to a 'foreign body'. She further pointed out that microplastics become carriers of toxins including mercury, pesticides and dioxins (a known cause of cancer and reproductive and developmental problems). These toxins accumulate in the fatty tissues once they enter the body through microplastics. Now this is being compounded massively by people putting plastic on their face and throwing it away.

Workers exposed to polypropylene plastic fibres known as 'flock' have developed 'flock worker's lung' from inhaling small pieces of the flock fibres which can damage lung tissue, reduce breathing capacity and exacerbate other respiratory problems. *Now* … commonly used surgical masks have three layers of melt-blown textiles made of … polypropylene. We have billions of people putting these microplastics against their mouth, nose and face for hours at a time day after day in the form of masks. How does anyone think that will work out? I mean – what could possibly go wrong? We posted a number of scientific studies on this at davidicke.com, but when I went back to them as I was writing this book the links to the science research website where they were hosted were dead. Anything that challenges the official narrative in any way is either censored or vilified. The official narrative is so unsupportable by the evidence that only deleting the truth can protect it. A study by Chinese scientists still survived – with the usual twist which it why it was still active, I guess. Yes, they found that virtually all the masks they tested increased the daily intake of microplastic fibres, but people should still wear them because the danger from the 'virus' was worse said the crazy 'team' from the Institute of Hydrobiology in Wuhan. Scientists first discovered microplastics in lung tissue of some patients who died of lung cancer in the 1990s. Subsequent studies have confirmed the potential health damage with the plastic degrading slowly and remaining in the lungs to accumulate in volume. Wuhan researchers used a machine simulating human breathing to establish that masks shed up to nearly 4,000 microplastic fibres in a month with reused masks producing more. Scientists said some masks are laced with toxic chemicals and a variety of compounds seriously restricted for both health and environmental reasons. They include cobalt (used in blue dye) and formaldehyde known to cause watery eyes, burning sensations in the eyes, nose, and throat, plus coughing, wheezing and nausea. No – that must be 'Covid-19'.

Mask 'worms'

There is another and potentially even more sinister content of masks. Mostly new masks of different makes filmed under a microscope around the world have been found to contain strange black fibres or 'worms' that appear to move or 'crawl' by themselves and react to heat and water. The nearest I have seen to them are the self-replicating fibres that are pulled out through the skin of those suffering from Morgellons disease which has been connected to the phenomena of 'chemtrails' which I will bring into the story later on. Morgellons fibres continue to grow outside the body and have a form of artificial intelligence. Black 'worm' fibres in masks have that kind of feel to them and there is a nanotechnology technique called 'worm micelles' which carry and release drugs or anything else you want to deliver to the body. For sure the suppression of humanity by mind altering drugs is the Cult agenda big time and the more excuses they can find to gain access to the body the more opportunities there are to make that happen whether through 'vaccines' or masks pushed against the mouth and nose for hours on end.

So let us summarise the pros and cons of masks:

Against masks: Breathing in your own carbon dioxide; depriving the body and brain of sufficient oxygen; build-up of toxins in the mask that can be breathed into the lungs and cause rashes on the face and 'mask-mouth'; breathing microplastic fibres and toxic chemicals into the lungs; dehumanisation and deleting individualisation by literally making people faceless; destroying human emotional interaction through facial expression and deleting parental connection with their babies which look for guidance to their facial expression.

For masks: They don't protect you from a 'virus' that doesn't exist and even if it did 'viral' particles are so minute they are smaller than the holes in the mask.

Governments, police, supermarkets, businesses, transport companies, and all the rest who seek to impose masks have done no risk assessment on their consequences for health and psychology and are now open to group lawsuits when the impact becomes clear with a cumulative epidemic of respiratory and other disease. Authorities will try to exploit these effects and hide the real cause by dubbing them 'Covid-19'. Can you imagine setting out to force the population to wear health-destroying masks without doing any assessment of the risks? It is criminal and it is evil, but then how many people targeted in this way, who see their children told to wear them all day at school, have asked for a risk assessment? Billions can't be imposed upon by the few unless the billions allow it. Oh, yes, with just a tinge of irony, 85 percent of all masks made worldwide come from *China*.

Wash your hands in toxic shite

'Covid' rules include the use of toxic sanitisers and again the health consequences of constantly applying toxins to be absorbed through the skin is obvious to any level of Renegade Mind. America's Food and Drug Administration (FDA) said that sanitisers are drugs and issued a warning about 75 dangerous brands which contain methanol used in antifreeze and can cause death, kidney damage and blindness. The FDA circulated the following warning even for those brands that it claims to be safe:

> Store hand sanitizer out of the reach of pets and children, and children should use it only with adult supervision. Do not drink hand sanitizer. This is particularly important for young children, especially toddlers, who may be attracted by the pleasant smell or brightly colored bottles of hand sanitizer.
>
> Drinking even a small amount of hand sanitizer can cause alcohol poisoning in children. (However, there is no need to be concerned if your children eat with or lick their hands after using hand sanitizer.) During this coronavirus pandemic, poison control centers have had an increase in calls about accidental ingestion of hand sanitizer, so it is important that adults monitor young children's use.
>
> Do not allow pets to swallow hand sanitizer. If you think your pet has eaten something potentially dangerous, call your veterinarian or a pet poison control center right away. Hand sanitizer is flammable and should be stored away from heat and flames. When using hand sanitizer, rub your hands until they feel completely dry before performing activities that may involve heat, sparks, static electricity, or open flames.

There you go, perfectly safe, then, and that's without even a mention of the toxins absorbed through the skin. Come on kids – sanitise your hands everywhere you go. It will save you from the 'virus'. Put all these elements together of the 'Covid' normal and see how much health and psychology is being cumulatively damaged, even devastated, to 'protect your health'. Makes sense, right? They are only imposing these things because they care, right? *Right?*

Submitting to insanity

Psychological reframing of the population goes very deep and is done in many less obvious ways. I hear people say how contradictory and crazy 'Covid' rules are and how they are ever changing. This is explained away by dismissing those involved as idiots. It is a big mistake. The Cult is delighted if its cold calculation is perceived as incompetence and idiocy when it is anything but. Oh, yes, there are idiots within the system – lots of them – but they are *administering* the Cult agenda, mostly unknowingly. They are not deciding and dictating it. The bulwark against tyranny is self-respect, always has been, always will be. It is self-respect that has broken every tyranny in history. By its very nature self-respect will not bow to oppression and its perpetrators. There is so little self-respect that it's always the few that overturn dictators. Many may eventually follow, but the few with the iron spines (self-respect) kick it off and generate the momentum. The Cult targets self-respect in the knowledge that once this has gone only submission remains. Crazy, contradictory, ever-changing 'Covid' rules are systematically applied by psychologists to delete self-respect. They *want* you to see that the rules make no sense. It is one thing to decide to do something when *you* have made the choice based on evidence and logic. You still retain your self-respect. It is quite another when you can see what you are being told to do is insane, ridiculous and makes no sense, and *yet you still do it*. Your self-respect is extinguished and this has been happening as ever more obviously stupid and nonsensical things have been demanded and the great majority have complied even when they can see they are stupid and nonsensical.

People walk around in face-nappies knowing they are damaging their health and make no difference to a 'virus'. They do it in fear of not doing it. I know it's daft, but I'll do it anyway. When that happens something dies inside of you and submissive reframing has begun. Next there's a need to hide from yourself that you have conceded your self-respect and you convince yourself that you have not really submitted to fear and intimidation. You begin to believe that you are complying with craziness because it's the right thing to do. When first you concede your self-respect of 2+2 = 4 to 2+2 = 5 you *know* you are compromising your self-respect. Gradually to avoid facing that fact you begin to *believe* that 2+2=5. You have been reframed and I have been watching this process happening in the human psyche on an industrial scale. The Cult is working to break your spirit and one of its major tools in that war is humiliation. I read how former American soldier Bradley Manning (later Chelsea Manning after a sex-change) was treated after being jailed for supplying WikiLeaks with documents exposing the enormity of government and elite mendacity. Manning was isolated in solitary confinement for eight months, put under 24-hour surveillance, forced to hand over clothing before going to bed, and stand naked for every roll call. This is systematic humiliation. The introduction of anal swab 'Covid' tests in China has been done for the same reason to delete self-respect and induce compliant submission. Anal swabs are mandatory for incoming passengers in parts of China and American diplomats have said they were forced to undergo the indignity which would have been calculated humiliation by the Cult-owned Chinese government that has America in its sights.

Government-people: An abusive relationship

Spirit-breaking psychological techniques include giving people hope and apparent respite from tyranny only to take it away again. This happened in the UK during Christmas, 2020, when the psycho-psychologists and their political lackeys announced an easing of restrictions over the holiday only to reimpose them almost immediately on the basis of yet another lie. There is a big psychological difference between getting used to oppression and being given hope of relief only to have that dashed. Psychologists know this and we have seen the technique used repeatedly. Then there is traumatising people before you introduce more extreme regulations that require compliance. A perfect case was the announcement by the dark and sinister Whitty and Vallance in the UK that 'new data' predicted that 4,000 could die every day over the winter of 2020/2021 if we did not lockdown again. I think they call it lying and after traumatising people with that claim out came Jackboot Johnson the next day with new curbs on human freedom. Psychologists know that a frightened and traumatised mind becomes suggestable to submission and behaviour reframing. Underpinning all this has been to make people fearful and suspicious of each other and see themselves as a potential danger to others. In league with deleted self-respect you have the perfect psychological recipe for self-loathing. The relationship between authority and public is now demonstrably the same as that of subservience to an abusive partner. These are signs of an abusive relationship explained by psychologist Leslie Becker-Phelps:

Psychological and emotional abuse: Undermining a partner's self-worth with verbal attacks, name-calling, and belittling. Humiliating the partner in public, unjustly accusing them of having an affair, or interrogating them about their every behavior. Keeping partner confused or off balance by saying they were just kidding or blaming the partner for 'making' them act this way … Feigning in public that they care while turning against them in private. This leads to victims frequently feeling confused, incompetent, unworthy, hopeless, and chronically self-doubting. [Apply these techniques to how governments have treated the population since New Year, 2020, and the parallels are obvious.]

Physical abuse: The abuser might physically harm their partner in a range of ways, such as grabbing, hitting, punching, or shoving them. They might throw objects at them or harm them with a weapon. [Observe the physical harm imposed by masks, lockdown, and so on.]

Threats and intimidation: One way abusers keep their partners in line is by instilling fear. They might be verbally threatening, or give threatening looks or gestures. Abusers often make it known that they are tracking their partner's every move. They might destroy their partner's possessions, threaten to harm them, or threaten to harm their family members. Not surprisingly, victims of this abuse often feel anxiety, fear, and panic. [No words necessary.]

Isolation: Abusers often limit their partner's activities, forbidding them to talk or interact with friends or family. They might limit access to a car or even turn off their phone. All of this might be done by physically holding them against their will, but is often accomplished through psychological abuse and intimidation. The more isolated a person feels, the fewer resources they have to help gain perspective on their situation and to escape from it. [No words necessary.]

Economic abuse: Abusers often make their partners beholden to them for money by controlling access to funds of any kind. They might prevent their partner from getting a job or withhold access to money they earn from a job. This creates financial dependency that makes leaving the relationship very difficult. [See destruction of livelihoods and the proposed meagre 'guaranteed income' so long as you do whatever you are told.]

Using children: An abuser might disparage their partner's parenting skills, tell their children lies about their partner, threaten to take custody of their children, or threaten to harm their children. These tactics instil fear and often elicit compliance. [See reframed social service mafia and how children are being mercilessly abused by the state over 'Covid' while their parents look on too frightened to do anything.]

A further recurring trait in an abusive relationship is the abused blaming themselves for their abuse and making excuses for the abuser. We have the public blaming each other for lockdown abuse by government and many making excuses for the government while attacking those who challenge the government. How often we have heard authorities say that rules are being imposed or reimposed only because people have refused to 'behave' and follow the rules. We don't want to do it – it's *you*.

Renegade Minds are an antidote to all of these things. They will never concede their self-respect no matter what the circumstances. Even when apparent humiliation is heaped upon them they laugh in its face and reflect back the humiliation on the abuser where it belongs. Renegade Minds will never wear masks they know are only imposed to humiliate, suppress and damage both physically and psychologically. Consequences will take care of themselves and they will never break their spirit or cause them to concede to tyranny. UK newspaper columnist Peter Hitchens was one of the few in the mainstream media to speak out against lockdowns and forced vaccinations. He then announced he had taken the jab. He wanted to see family members abroad and he believed vaccine passports were inevitable even though they had not yet been introduced. Hitchens has a questioning and critical mind, but not a Renegade one. If he had no amount of pressure would have made him concede. Hitchens excused his action by saying that the battle has been lost. Renegade Minds never accept defeat when freedom is at stake and even if they are the last one standing the self-respect of not submitting to tyranny is more important than any outcome or any consequence.

That's why Renegade Minds are the only minds that ever changed anything worth changing.

CHAPTER EIGHT

'Reframing' insanity

Insanity is relative. It depends on who has who locked in what cage
Ray Bradbury

'Reframing' a mind means simply to change its perception and behaviour. This can be done subconsciously to such an extent that subjects have no idea they have been 'reframed' while to any observer changes in behaviour and attitudes are obvious.

Human society is being reframed on a ginormous scale since the start of 2020 and here we have the reason why psychologists rather than doctors have been calling the shots. Ask most people who have succumbed to 'Covid' reframing if they have changed and most will say 'no'; but they *have* and fundamentally. The Cult's long-game has been preparing for these times since way back and crucial to that has been to prepare both population and officialdom mentally and emotionally. To use the mind-control parlance they had to reframe the population with a mentality that would submit to fascism and reframe those in government and law enforcement to impose fascism or at least go along with it. The result has been the fact-deleted mindlessness of 'Wokeness' and officialdom that has either enthusiastically or unquestioningly imposed global tyranny demanded by reframed politicians on behalf of psychopathic and deeply evil cultists. 'Cognitive reframing' identifies and challenges the way someone sees the world in the form of situations, experiences and emotions and then restructures those perceptions to view the same set of circumstances in a different way. This can have benefits if the attitudes are personally destructive while on the other side it has the potential for individual and collective mind control which the subject has no idea has even happened.

Cognitive therapy was developed in the 1960s by Aaron T. Beck who was born in Rhode Island in 1921 as the son of Jewish immigrants from the Ukraine. He became interested in the techniques as a treatment for depression. Beck's daughter Judith S. Beck is prominent in the same field and they founded the Beck Institute for Cognitive Behavior Therapy in Philadelphia in 1994. Cognitive reframing, however, began to be used worldwide by those with a very dark agenda. The Cult reframes politicians to change their attitudes and actions until they are completely at odds with what they once appeared to stand for. The same has been happening to government administrators at all levels, law enforcement, military and the human population. Cultists love mind control for two main reasons: It allows them to control what people think, do and say to secure agenda advancement and, by definition, it calms their legendary insecurity and fear of the unexpected. I have studied mind control since the time I travelled America in 1996. I may have been talking to next to no one in terms of an audience in those years, but my goodness did I gather a phenomenal amount of information and knowledge about so many things including the techniques of mind control. I have described this in detail in other books going back to *The Biggest Secret* in 1998. I met a very large number of people recovering from MKUltra and its offshoots and successors and I began to see how these same techniques were being used on the population in general. This was never more obvious than since the 'Covid' hoax began.

Reframing the enforcers

I have observed over the last two decades and more the very clear transformation in the dynamic between the police, officialdom and the public. I tracked this in the books as the relationship mutated from one of serving the public to seeing them as almost the enemy and certainly a lower caste. There has always been a class divide based on income and always been some psychopathic, corrupt, and big-I-am police officers. This was different. Wholesale change was unfolding in the collective dynamic; it was less about money and far more about position and perceived power. An us-and-them was emerging. Noses were lifted skyward by government administration and law enforcement and their attitude to the public they were *supposed* to be serving changed to one of increasing contempt, superiority and control. The transformation was so clear and widespread that it had to be planned. Collective attitudes and dynamics do not change naturally and organically that quickly on that scale. I then came across an organisation in Britain called Common Purpose created in the late 1980s by Julia Middleton who would work in the office of Deputy Prime Minister John Prescott during the long and disastrous premiership of war criminal Tony Blair. When Blair speaks the Cult is speaking and the man should have been in jail a long time ago. Common Purpose proclaims itself to be one of the biggest 'leadership development' organisations in the world while functioning as a *charity* with all the financial benefits which come from that. It hosts 'leadership development' courses and programmes all over the world and claims to have 'brought together' what it calls 'leaders' from more than 100 countries on six continents. The modus operandi of Common Purpose can be compared with the work of the UK government's reframing network that includes the Behavioural Insights Team 'nudge unit' and 'Covid' reframing specialists at SPI-B. WikiLeaks described Common Purpose long ago as 'a hidden virus in our government and schools' which is unknown to the general public: 'It recruits and trains "leaders" to be loyal to the directives of Common Purpose and the EU, instead of to their own departments, which they then undermine or subvert, the NHS [National Health Service] being an example.' This is a vital point to understand the 'Covid' hoax. The NHS, and its equivalent around the world, has been utterly reframed in terms of administrators and much of the medical personnel with the transformation underpinned by recruitment policies. The outcome has been the criminal and psychopathic behaviour of the

NHS over ‘Covid’ and we have seen the same in every other major country. WikiLeaks said Common Purpose trainees are ‘learning to rule without regard to democracy’ and to usher in a police state (current events explained). Common Purpose operated like a ‘glue’ and had members in the NHS, BBC, police, legal profession, church, many of Britain’s 7,000 quangos, local councils, the Civil Service, government ministries and Parliament, and controlled many RDA’s (Regional Development Agencies). Here we have one answer for how and why British institutions and their like in other countries have changed so negatively in relation to the public. This further explains how and why the beyond-disgraceful reframed BBC has become a propaganda arm of ‘Covid’ fascism. They are all part of a network pursuing the same goal.

By 2019 Common Purpose was quoting a figure of 85,000 ‘leaders’ that had attended its programmes. These ‘students’ of all ages are known as Common Purpose ‘graduates’ and they consist of government, state and local government officials and administrators, police chiefs and officers, and a whole range of others operating within the national, local and global establishment. Cressida Dick, Commissioner of the London Metropolitan Police, is the Common Purpose graduate who was the ‘Gold Commander’ that oversaw what can only be described as the murder of Brazilian electrician Jean Charles de Menezes in 2005. He was held down by psychopathic police and shot seven times in the head by a psychopathic lunatic after being mistaken for a terrorist when he was just a bloke going about his day. Dick authorised officers to pursue and keep surveillance on de Menezes and ordered that he be stopped from entering the underground train system. Police psychopaths took her at her word clearly. She was ‘disciplined’ for this outrage by being *promoted* – eventually to the top of the ‘Met’ police where she has been a disaster. Many Chief Constables controlling the police in different parts of the UK are and have been Common Purpose graduates. I have heard the ‘graduate’ network described as a sort of Mafia or secret society operating within the fabric of government at all levels pursuing a collective policy ingrained at Common Purpose training events. Founder Julia Middleton herself has said:

> Locally and internationally, Common Purpose graduates will be 'lighting small fires' to create change in their organisations and communities … The Common Purpose effect is best illustrated by the many stories of small changes brought about by leaders, who themselves have changed.

A Common Purpose mission statement declared:

> Common Purpose aims to improve the way society works by expanding the vision, decision-making ability and influence of all kinds of leaders. The organisation runs a variety of educational programmes for leaders of all ages, backgrounds and sectors, in order to provide them with the inspirational, information and opportunities they need to change the world.

Yes, but into what? Since 2020 the answer has become clear.

NLP and the Delphi technique

Common Purpose would seem to be a perfect name or would common programming be better? One of the foundation methods of reaching 'consensus' (group think) is by setting the agenda theme and then encouraging, cajoling or pressuring everyone to agree a 'consensus' in line with the core theme promoted by Common Purpose. The methodology involves the 'Delphi technique', or an adaption of it, in which opinions are expressed that are summarised by a 'facilitator or change agent' at each stage. Participants are 'encouraged' to modify their views in the light of what others have said. Stage by stage the former individual opinions are merged into group consensus which just happens to be what Common Purpose wants them to believe. A key part of this is to marginalise anyone refusing to concede to group think and turn the group against them to apply pressure to conform. We are seeing this very technique used on the general population to make 'Covid' group-thinkers hostile to those who have seen through the bullshit. People can be reframed by using perception manipulation methods such as Neuro-Linguistic Programming (NLP) in which you change perception with the use of carefully constructed language. An NLP website described the technique this way:

> … A method of influencing brain behaviour (the 'neuro' part of the phrase) through the use of language (the 'linguistic' part) and other types of communication to enable a person to 'recode' the way the brain responds to stimuli (that's the 'programming') and manifest new and better behaviours. Neuro-Linguistic Programming often incorporates hypnosis and self-hypnosis to help achieve the change (or 'programming') that is wanted.

British alternative media operation UKColumn has done very detailed research into Common Purpose over a long period. I quoted co-founder and former naval officer Brian Gerrish in my book *Remember Who You Are*, published in 2011, as saying the following years before current times:

> It is interesting that many of the mothers who have had children taken by the State speak of the Social Services people being icily cool, emotionless and, as two ladies said in slightly different words, '… like little robots'. We know that NLP is cumulative, so people can be given small imperceptible doses of NLP in a course here, another in a few months, next year etc. In this way, major changes are accrued in their personality, but the day by day change is almost unnoticeable.

In these and other ways 'graduates' have had their perceptions uniformly reframed and they return to their roles in the institutions of government, law enforcement, legal profession, military, 'education', the UK National Health Service and the whole swathe of the establishment structure to pursue a common agenda preparing for the 'post-industrial', 'post-democratic' society. I say 'preparing' but we are now there. 'Post-industrial' is code for the Great Reset and 'post-democratic' is 'Covid' fascism. UKColumn has spoken to partners of those who have attended Common Purpose 'training'. They have described how personalities and attitudes of 'graduates' changed very noticeably for the worse by the time they had completed the course. They had been 'reframed' and told they are the 'leaders' – the special ones – who know better than the population. There has also been the very demonstrable recruitment of psychopaths and narcissists into government administration at all levels and law enforcement. If you want psychopathy hire psychopaths and you get a simple cause and effect. If you want administrators, police officers and 'leaders' to perceive the public as lesser beings who don't matter then employ narcissists. These personalities are identified using 'psychometrics' that identifies knowledge, abilities, attitudes and personality traits, mostly through carefully-designed questionnaires and tests. As this policy has passed through the decades we have had power-crazy, power-trippers appointed into law enforcement, security and government administration in preparation for current times and the dynamic between public and law enforcement/officialdom has been transformed. UKColumn's Brian Gerrish said of the narcissistic personality:

> Their love of themselves and power automatically means that they will crush others who get in their way. I received a major piece of the puzzle when a friend pointed out that when they made public officials re-apply for their own jobs several years ago they were also required to do psychometric tests. This was undoubtedly the start of the screening process to get 'their' sort of people in post.

How obvious that has been since 2020 although it was clear what was happening long before if people paid attention to the changing public-establishment dynamic.

Change agents

At the centre of events in 'Covid' Britain is the National Health Service (NHS) which has behaved disgracefully in slavishly following the Cult agenda. The NHS management structure is awash with Common Purpose graduates or 'change agents' working to a common cause. Helen Bevan, a Chief of Service Transformation at the NHS Institute for Innovation and Improvement, co-authored a document called 'Towards a million change agents, a review of the social movements literature: implications for large scale change in the NHS'. The document compared a project management approach to that of change and social movements where 'people change themselves and each other – peer to peer'. Two definitions given for a 'social movement' were:

A group of people who consciously attempt to build a radically new social order; involves people of a broad range of social backgrounds; and deploys politically confrontational and socially disruptive tactics – Cyrus Zirakzadeh 1997

Collective challenges, based on common purposes and social solidarities, in sustained interaction with elites, opponents, and authorities – Sidney Tarrow 1994

Helen Bevan wrote another NHS document in which she defined 'framing' as 'the process by which leaders construct, articulate and put across their message in a powerful and compelling way in order to win people to their cause and call them to action'. I think I could come up with another definition that would be rather more accurate. The National Health Service and institutions of Britain and the wider world have been taken over by reframed 'change agents' and that includes everything from the United Nations to national governments, local councils and social services which have been kidnapping children from loving parents on an extraordinary and gathering scale on the road to the end of parenthood altogether. Children from loving homes are stolen and kidnapped by the state and put into the 'care' (inversion) of the local authority through council homes, foster parents and forced adoption. At the same time children are allowed to be abused without response while many are under council 'care'. UKColumn highlighted the Common Purpose connection between South Yorkshire Police and Rotherham council officers in the case of the scandal in that area of the sexual exploitation of children to which the authorities turned not one blind eye, but both:

> We were alarmed to discover that the Chief Executive, the Strategic Director of Children and Young People's Services, the Manager for the Local Strategic Partnership, the Community Cohesion Manager, the Cabinet Member for Cohesion, the Chief Constable and his predecessor had all attended Leadership training courses provided by the pseudo-charity Common Purpose.

Once 'change agents' have secured positions of hire and fire within any organisation things start to move very quickly. Personnel are then hired and fired on the basis of whether they will work towards the agenda the change agent represents. If they do they are rapidly promoted even though they may be incompetent. Those more qualified and skilled who are pre-Common Purpose 'old school' see their careers stall and even disappear. This has been happening for decades in every institution of state, police, 'health' and social services and all of them have been transformed as a result in their attitudes to their jobs and the public. Medical professions, including nursing, which were once vocations for the caring now employ many cold, callous and couldn't give a shit personality types. The UKColumn investigation concluded:

> By blurring the boundaries between people, professions, public and private sectors, responsibility and accountability, Common Purpose encourages 'graduates' to believe that as new selected leaders, they can work together, outside of the established political and social structures, to achieve a paradigm shift or CHANGE – so called 'Leading Beyond Authority'. In doing so, the allegiance of the individual becomes 'reframed' on CP colleagues and their NETWORK.

Reframing the Face-Nappies

Nowhere has this process been more obvious than in the police where recruitment of psychopaths and development of unquestioning mind-controlled group-thinkers have transformed law enforcement into a politically-correct 'Woke' joke and a travesty of what should be public service. Today they wear their face-nappies like good little gofers and enforce 'Covid' rules which are fascism under another name. Alongside the specifically-recruited psychopaths we have software minds incapable of free thought. Brian Gerrish again:

An example is the policeman who would not get on a bike for a press photo because he had not done the cycling proficiency course. Normal people say this is political correctness gone mad. Nothing could be further from the truth. The policeman has been reframed, and in his reality it is perfect common sense not to get on the bike 'because he hasn't done the cycling course'.

Another example of this is where the police would not rescue a boy from a pond until they had taken advice from above on the 'risk assessment'. A normal person would have arrived, perhaps thought of the risk for a moment, and dived in. To the police now 'reframed', they followed 'normal' procedure.

There are shocking cases of reframed ambulance crews doing the same. Sheer unthinking stupidity of London Face-Nappies headed by Common Purpose graduate Cressida Dick can be seen in their behaviour at a vigil in March, 2021, for a murdered woman, Sarah Everard. A police officer had been charged with the crime. Anyone with a brain would have left the vigil alone in the circumstances. Instead they 'manhandled' women to stop them breaking 'Covid rules' to betray classic reframing. Minds in the thrall of perception control have no capacity for seeing a situation on its merits and acting accordingly. 'Rules is rules' is their only mind-set. My father used to say that rules and regulations are for the guidance of the intelligent and the blind obedience of the idiot. Most of the intelligent, decent, coppers have gone leaving only the other kind and a few old school for whom the job must be a daily nightmare. The combination of psychopaths and rule-book software minds has been clearly on public display in the 'Covid' era with automaton robots in uniform imposing fascistic 'Covid' regulations on the population without any personal initiative or judging situations on their merits. There are thousands of examples around the world, but I'll make my point with the infamous Derbyshire police in the English East Midlands – the ones who think pouring dye into beauty spots and using drones to track people walking in the countryside away from anyone is called 'policing'. To them there are rules decreed by the government which they have to enforce and in their bewildered state a group gathering in a closed space and someone walking alone in the countryside are the same thing. It is beyond idiocy and enters the realm of clinical insanity.

Police officers in Derbyshire said they were 'horrified' – *horrified* – to find 15 to 20 'irresponsible' kids playing a football match at a closed leisure centre 'in breach of coronavirus restrictions'. When they saw the police the kids ran away leaving their belongings behind and the reframed men and women of Derbyshire police were seeking to establish their identities with a view to fining their parents. The most natural thing for youngsters to do – kicking a ball about – is turned into a criminal activity and enforced by the moronic software programs of Derbyshire police. You find the same mentality in every country. These barely conscious 'horrified' officers said they had to take action because 'we need to ensure these rules are being followed' and 'it is of the utmost importance that you ensure your children are following the rules and regulations for Covid-19'. Had any of them done ten seconds of research to see if this parroting of their masters' script could be supported by any evidence? Nope. Reframed people don't think – others think for them and that's the whole idea of reframing. I have seen police officers one after the other repeating without question word for word what officialdom tells them just as I have seen great swathes of the public doing the same. Ask either for 'their' opinion and out spews what they have been told to think by the official narrative. Police and public may seem to be in different groups, but their mentality is the same. Most people do whatever they are told in fear not doing so or because they believe what officialdom tells them; almost the entirety of the police do what they are told for the same reason. Ultimately it's the tiny inner core of the global Cult that's telling both what to do.

So Derbyshire police were 'horrified'. Oh, really? Why did they think those kids were playing football? It was to relieve the psychological consequences of lockdown and being denied human contact with their friends and interaction, touch and discourse vital to human psychological health. Being denied this month after month has dismantled the psyche of many children and young people as depression and suicide have exploded. Were Derbyshire police *horrified by that*? Are you kidding? Reframed people don't have those mental and emotional processes that can see how the impact on the psychological health of youngsters is far more dangerous than any ‘virus’ even if you take the mendacious official figures to be true. The reframed are told (programmed) how to act and so they do. The Derbyshire Chief Constable in the first period of lockdown when the black dye and drones nonsense was going on was Peter Goodman. He was the man who severed the connection between his force and the Derbyshire Constabulary *Male Voice* Choir when he decided that it was not inclusive enough to allow women to join. The fact it was a male voice choir making a particular sound produced by male voices seemed to elude a guy who terrifyingly ran policing in Derbyshire. He retired weeks after his force was condemned as disgraceful by former Supreme Court Justice Jonathan Sumption for their behaviour over extreme lockdown impositions. Goodman was replaced by his deputy Rachel Swann who was in charge when her officers were ‘horrified’. The police statement over the boys committing the hanging-offence of playing football included the line about the youngsters being ‘irresponsible in the times we are all living through’ missing the point that the real relevance of the ‘times we are all living through’ is the imposition of fascism enforced by psychopaths and reframed minds of police officers playing such a vital part in establishing the fascist tyranny that their own children and grandchildren will have to live in their entire lives. As a definition of insanity that is hard to beat although it might be run close by imposing masks on people that can have a serious effect on their health while wearing a face nappy all day themselves. Once again public and police do it for the same reason – the authorities tell them to and who are they to have the self-respect to say no?

Wokers in uniform

How reframed do you have to be to arrest a *six-year-old* and take him to court for *picking a flower* while waiting for a bus? Brain dead police and officialdom did just that in North Carolina where criminal proceedings happen regularly for children under nine. Attorney Julie Boyer gave the six-year-old crayons and a colouring book during the ‘flower’ hearing while the ‘adults’ decided his fate. County Chief District Court Judge Jay Corpening asked: ‘Should a child that believes in Santa Claus, the Easter Bunny and the tooth fairy be making life-altering decisions?’ Well, of course not, but common sense has no meaning when you have a common purpose and a reframed mind. Treating children in this way, and police operating in American schools, is all part of the psychological preparation for children to accept a police state as normal all their adult lives. The same goes for all the cameras and biometric tracking technology in schools. Police training is focused on reframing them as snowflake Wokers and this is happening in the military. Pentagon top brass said that ‘training sessions on extremism’ were needed for troops who asked why they were so focused on the Capitol Building riot when Black Lives Matter riots were ignored. What’s the difference between them some apparently and rightly asked. Actually, there is a difference. Five people died in the Capitol riot, only one through violence, and that was a police officer shooting an unarmed protestor. BLM riots killed at least 25 people and cost billions. Asking the question prompted the psychopaths and reframed minds that run the Pentagon to say that more ‘education’ (programming) was needed. Troop training is all based on psychological programming to make them fodder for the Cult – ‘Military men are just dumb, stupid animals to be used as pawns in foreign policy’ as Cult-to-his-DNA former Secretary of State Henry Kissinger famously said. Governments see the police in similar terms and it’s time for those among them who can see this to defend the people and stop being enforcers of the Cult agenda upon the people.

The US military, like the country itself, is being targeted for destruction through a long list of Woke impositions. Cult-owned gaga ‘President’ Biden signed an executive order when he took office to allow taxpayer money to pay for transgender surgery for active military personnel and veterans. Are you a man soldier? No, I’m a LGBTQIA+ with a hint of Skoliosexual and Spectrasexual. Oh, good man. Bad choice of words you bigot. The Pentagon announced in March, 2021, the appointment of the first ‘diversity and inclusion officer' for US Special Forces. Richard Torres-Estrada arrived with the publication of a 'D&I Strategic Plan which will guide the enterprise-wide effort to institutionalize and sustain D&I'. If you think a Special Forces 'Strategic Plan' should have something to do with defending America you haven't been paying attention. Defending Woke is now the military's new role. Torres-Estrada has posted images comparing Donald Trump with Adolf Hitler and we can expect no bias from him as a representative of the supposedly non-political Pentagon. Cable news host Tucker Carlson said: 'The Pentagon is now the Yale faculty lounge but with cruise missiles.' Meanwhile Secretary of Defense Lloyd Austin, a board member of weapons-maker Raytheon with stock and compensation interests in October, 2020, worth $1.4 million, said he was purging the military of the 'enemy within' – anyone who isn't Woke and supports Donald Trump. Austin refers to his targets as 'racist extremists' while in true Woke fashion being himself a racist extremist. Pentagon documents pledge to 'eradicate, eliminate and conquer all forms of racism, sexism and homophobia'. The definitions of these are decided by 'diversity and inclusion committees' peopled by those who see racism, sexism and homophobia in every situation and opinion. Woke (the Cult) is dismantling the US military and purging testosterone as China expands its military and gives its troops 'masculinity training'. How do we think that is going to end when this is all Cult coordinated? The US military, like the British military, is controlled by Woke and spineless top brass who just go along with it out of personal career interests.

'Woke' means fast asleep

Mind control and perception manipulation techniques used on individuals to create group-think have been unleashed on the global population in general. As a result many have no capacity to see the obvious fascist agenda being installed all around them or what 'Covid' is really all about. Their brains are firewalled like a computer system not to process certain concepts, thoughts and realisations that are bad for the Cult. The young are most targeted as the adults they will be when the whole fascist global state is planned to be fully implemented. They need to be prepared for total compliance to eliminate all pushback from entire generations. The Cult has been pouring billions into taking complete control of ‘education’ from schools to universities via its operatives and corporations and not least Bill Gates as always. The plan has been to transform ‘education’ institutions into programming centres for the mentality of ‘Woke’. James McConnell, professor of psychology at the University of Michigan, wrote in *Psychology Today* in 1970:

> The day has come when we can combine sensory deprivation with drugs, hypnosis, and astute manipulation of reward and punishment, to gain almost absolute control over an individual’s behaviour. It should then be possible to achieve a very rapid and highly effective type of brainwashing that would allow us to make dramatic changes in a person’s behaviour and personality ...
>
> … We should reshape society so that we all would be trained from birth to want to do what society wants us to do. We have the techniques to do it... no-one owns his own personality you acquired, and there’s no reason to believe you should have the right to refuse to acquire a new personality if your old one is anti-social.

This was the potential for mass brainwashing in 1970 and the mentality there displayed captures the arrogant psychopathy that drives it forward. I emphasise that not all young people have succumbed to Woke programming and those that haven’t are incredibly impressive people given that today’s young are the most perceptually-targeted generations in history with all the technology now involved. Vast swathes of the young generations, however, have fallen into the spell – and that’s what it is – of Woke. The Woke mentality and perceptual program is founded on *inversion* and you will appreciate later why that is so significant. Everything with Woke is inverted and the opposite of what it is claimed to be. Woke was a term used in African-American culture from the 1900s and referred to an awareness of social and racial justice. This is not the meaning of the modern version or ‘New Woke’ as I call it in *The Answer*. Oh, no, Woke today means something very different no matter how much Wokers may seek to hide that and insist Old Woke and New

Woke are the same. See if you find any ‘awareness of social justice’ here in the modern variety:

- Woke demands ‘inclusivity’ while excluding anyone with a different opinion and calls for mass censorship to silence other views.
- Woke claims to stand against oppression when imposing oppression is the foundation of all that it does. It is the driver of political correctness which is nothing more than a Cult invention to manipulate the population to silence itself.
- Woke believes itself to be ‘liberal’ while pursuing a global society that can only be described as fascist (see ‘anti-fascist’ fascist Antifa).
- Woke calls for ‘social justice’ while spreading injustice wherever it goes against the common ‘enemy’ which can be easily identified as a differing view.
- Woke is supposed to be a metaphor for ‘awake’ when it is solid-gold asleep and deep in a Cult-induced coma that meets the criteria for ‘off with the fairies’.

I state these points as obvious facts if people only care to look. I don’t do this with a sense of condemnation. We need to appreciate that the onslaught of perceptual programming on the young has been incessant and merciless. I can understand why so many have been reframed, or, given their youth, framed from the start to see the world as the Cult demands. The Cult has had access to their minds day after day in its ‘education’ system for their entire formative years. Perception is formed from information received and the Cult-created system is a life-long download of information delivered to elicit a particular perception, thus behaviour. The more this has expanded into still new extremes in recent decades and ever-increasing censorship has deleted other opinions and information why wouldn’t that lead to a perceptual reframing on a mass scale? I have described already cradle-to-grave programming and in more recent times the targeting of young minds from birth to adulthood has entered the stratosphere. This has taken the form of skewing what is ‘taught’ to fit the Cult agenda and the omnipresent techniques of group-think to isolate non-believers and pressure them into line. There has always been a tendency to follow the herd, but we really are in a new world now in relation to that. We have parents who can see the ‘Covid’ hoax told by their children not to stop them wearing masks at school, being ‘Covid’ tested or having the ‘vaccine’ in fear of the peer-pressure consequences of being different. What is ‘peer-pressure’ if not pressure to conform to group-think? Renegade Minds never group-think and always retain a set of perceptions that are unique to them. Group-think is always underpinned by consequences for not group-thinking. Abuse now aimed at those refusing DNA-manipulating ‘Covid vaccines’ are a potent example of this. The biggest pressure to conform comes from the very group which is itself being manipulated. ‘I am programmed to be part of a hive mind and so you must be.’

Woke control structures in ‘education’ now apply to every mainstream organisation. Those at the top of the ‘education’ hierarchy (the Cult) decide the policy. This is imposed on governments through the Cult network; governments impose it on schools, colleges and universities; their leadership impose the policy on teachers and academics and they impose it on children and students. At any level where there is resistance, perhaps from a teacher or university lecturer, they are targeted by the authorities and often fired. Students themselves regularly demand the dismissal of academics (increasingly few) at odds with the narrative that the students have been programmed to believe in. It is quite a thought that students who are being targeted by the Cult become so consumed by programmed group-think that they launch protests and demand the removal of those who are trying to push back against those targeting the students. Such is the scale of perceptual inversion. We see this with ‘Covid’ programming as the Cult imposes the rules via psycho-psychologists and governments on shops, transport companies and businesses which impose them on their staff who impose them on their customers who pressure Pushbackers to conform to the will of the Cult which is in the process of destroying them and their families. Scan all aspects of society and you will see the same sequence every time.

Fact free Woke and hijacking the 'left'

There is no more potent example of this than 'Woke', a mentality only made possible by the deletion of factual evidence by an 'education' system seeking to produce an ever more uniform society. Why would you bother with facts when you don't know any? Deletion of credible history both in volume and type is highly relevant. Orwell said: 'Who controls the past controls the future: who controls the present controls the past.' They who control the perception of the past control the perception of the future and they who control the present control the perception of the past through the writing and deleting of history. Why would you oppose the imposition of Marxism in the name of Wokeism when you don't know that Marxism cost at least 100 million lives in the 20th century alone? Watch videos and read reports in which Woker generations are asked basic historical questions – it's mind-blowing. A survey of 2,000 people found that six percent of millennials (born approximately early1980s to early 2000s) believed the Second World War (1939-1945) broke out with the assassination of President Kennedy (in 1963) and one in ten thought Margaret Thatcher was British Prime Minister at the time. She was in office between 1979 and 1990. We are in a post-fact society. Provable facts are no defence against the fascism of political correctness or Silicon Valley censorship. Facts don't matter anymore as we have witnessed with the 'Covid' hoax. Sacrificing uniqueness to the Woke group-think religion is all you are required to do and that means thinking for yourself is the biggest Woke no, no. All religions are an expression of group-think and censorship and Woke is just another religion with an orthodoxy defended by group-think and censorship. Burned at the stake becomes burned on Twitter which leads back eventually to burned at the stake as Woke humanity regresses to ages past.

The biggest Woke inversion of all is its creators and funders. I grew up in a traditional left of centre political household on a council estate in Leicester in the 1950s and 60s – you know, the left that challenged the power of wealth-hoarding elites and threats to freedom of speech and opinion. In those days students went on marches defending freedom of speech while today's Wokers march for its deletion. What on earth could have happened? Those very elites (collectively the Cult) that we opposed in my youth and early life have funded into existence the antithesis of that former left and hijacked the 'brand' while inverting everything it ever stood for. We have a mentality that calls itself 'liberal' and 'progressive' while acting like fascists. Cult billionaires and their corporations have funded themselves into control of 'education' to ensure that Woke programming is unceasing throughout the formative years of children and young people and that non-Wokers are isolated (that word again) whether they be students, teachers or college professors. The Cult has funded into existence the now colossal global network of Woke organisations that have spawned and promoted all the 'causes' on the Cult wish-list for global transformation and turned Wokers into demanders of them. Does anyone really think it's a coincidence that the Cult agenda for humanity is a carbon (sorry) copy of the societal transformations desired by Woke?? These are only some of them:

Political correctness: The means by which the Cult deletes all public debates that it knows it cannot win if we had the free-flow of information and evidence.

Human-caused 'climate change': The means by which the Cult seeks to transform society into a globally-controlled dictatorship imposing its will over the fine detail of everyone's lives 'to save the planet' which doesn't actually need saving.

Transgender obsession: Preparing collective perception to accept the 'new human' which would not have genders because it would be created technologically and not through procreation. I'll have much more on this in Human 2.0.

Race obsession: The means by which the Cult seeks to divide and rule the population by triggering racial division through the perception that society is more racist than ever when the opposite is the case. Is it perfect in that regard? No. But to compare today with the racism of apartheid and segregation brought to an end by the civil rights movement in the 1960s is to insult the memory of that movement and inspirations like Martin Luther King. Why is the 'anti-racism' industry (which it is) so dominated by privileged white people?

White supremacy: This is a label used by privileged white people to demonise poor and deprived white people pushing back on tyranny to marginalise and destroy them. White people are being especially targeted as the dominant race by number within Western society which the Cult seeks to transform in its image. If you want to change a society you must weaken and undermine its biggest group and once you have done that by using the other groups you next turn on them to do the same … 'Then they came for the Jews and I was not a Jew so I did nothing.'

Mass migration: The mass movement of people from the Middle East, Africa and Asia into Europe, from the south into the United States and from Asia into Australia are another way the Cult seeks to dilute the racial, cultural and political influence of white people on Western society. White people ask why their governments appear to be working against them while being politically and culturally biased towards incoming cultures. Well, here's your answer. In the same way sexually 'straight' people, men and women, ask why the authorities are biased against them in favour of other sexualities. The answer is the same – that's the way the Cult wants it to be for very sinister motives.

These are all central parts of the Cult agenda and central parts of the Woke agenda and Woke was created and continues to be funded to an immense degree by Cult billionaires and corporations. If anyone begins to say 'coincidence' the syllables should stick in their throat.

Billionaire 'social justice warriors'

Joe Biden is a 100 percent-owned asset of the Cult and the Wokers' man in the White House whenever he can remember his name and for however long he lasts with his rapidly diminishing cognitive function. Even walking up the steps of an aircraft without falling on his arse would appear to be a challenge. He's not an empty-shell puppet or anything. From the minute Biden took office (or the Cult did) he began his executive orders promoting the Woke wish-list. You will see the Woke agenda imposed ever more severely because it's really the *Cult* agenda. Woke organisations and activist networks spawned by the Cult are funded to the extreme so long as they promote what the Cult wants to happen. Woke is funded to promote 'social justice' by billionaires who become billionaires by destroying social justice. The social justice mantra is only a cover for dismantling social justice and funded by billionaires that couldn't give a damn about social justice. Everything makes sense when you see that. One of Woke's premier funders is Cult billionaire financier George Soros who said: 'I am basically there to make money, I cannot and do not look at the social consequences of what I do.' This is the same Soros who has given more than $32 billion to his Open Society Foundations global Woke network and funded Black Lives Matter, mass immigration into Europe and the United States, transgender activism, climate change activism, political correctness and groups targeting 'white supremacy' in the form of privileged white thugs that dominate Antifa. What a scam it all is and when you are dealing with the unquestioning fact-free zone of Woke scamming them is child's play. All you need to pull it off in all these organisations are a few in-the-know agents of the Cult and an army of naïve, reframed, uninformed, narcissistic, know-nothings convinced of their own self-righteousness, self-purity and virtue.

Soros and fellow billionaires and billionaire corporations have poured hundreds of millions into Black Lives Matter and connected groups and promoted them to a global audience. None of this is motivated by caring about black people. These are the billionaires that have controlled and exploited a system that leaves millions of black people in abject poverty and deprivation which they do absolutely nothing to address. The same Cult networks funding BLM were behind the *slave trade!* Black Lives Matter hijacked a phrase that few would challenge and they have turned this laudable concept into a political weapon to divide society. You know that BLM is a fraud when it claims that *All* Lives Matter, the most inclusive statement of all, is 'racist'. BLM and its Cult masters don't want to end racism. To them it's a means to an end to control all of humanity never mind the colour, creed, culture or background. What has destroying the nuclear family got to do with ending racism? Nothing – but that is one of the goals of BLM and also happens to be a goal of the Cult as I have been exposing in my books for decades. Stealing children from loving parents and giving schools ever more power to override parents is part of that same agenda. BLM is a Marxist organisation and why would that not be the case when the Cult created Marxism *and* BLM? Patrisse Cullors, a BLM co-founder, said in a 2015 video that she and her fellow organisers, including co-founder Alicia Garza, are 'trained Marxists'. The lady known after marriage as Patrisse Khan-Cullors bought a $1.4 million home in 2021 in one of the whitest areas of California with a black population of just 1.6 per cent and has so far bought *four* high-end homes for a total of $3.2 million. How very Marxist. There must be a bit of spare in the BLM coffers, however, when Cult corporations and billionaires have handed over the best part of $100 million. Many black people can see that Black Lives Matter is not working for them, but against them, and this is still more confirmation. Black journalist Jason Whitlock, who had his account suspended by Twitter for simply linking to the story about the 'Marxist's' home buying spree, said that BLM leaders are 'making millions of dollars off the backs of these dead black men who they wouldn't spit on if they were on fire and alive'.

Black Lies Matter

Cult assets and agencies came together to promote BLM in the wake of the death of career criminal George Floyd who had been jailed a number of times including for forcing his way into the home of a black woman with others in a raid in which a gun was pointed at her stomach. Floyd was filmed being held in a Minneapolis street in 2020 with the knee of a police officer on his neck and he subsequently died. It was an appalling thing for the officer to do, but the same technique has been used by police on peaceful protestors of lockdown without any outcry from the Woke brigade. As unquestioning supporters of the Cult agenda Wokers have supported lockdown and all the 'Covid' claptrap while attacking anyone standing up to the tyranny imposed in its name. Court documents would later include details of an autopsy on Floyd by County Medical Examiner Dr Andrew Baker who concluded that Floyd had taken a fatal level of the drug fentanyl. None of this mattered to fact-free, question-free, Woke. Floyd's death was followed by worldwide protests against police brutality amid calls to defund the police. Throwing babies out with the bathwater is a Woke speciality. In the wake of the murder of British woman Sarah Everard a Green Party member of the House of Lords, Baroness Jones of Moulescoomb (Nincompoopia would have been better), called for a 6pm curfew for all men. This would be in breach of the Geneva Conventions on war crimes which ban collective punishment, but that would never have crossed the black and white Woke mind of Baroness Nincompoopia who would have been far too convinced of her own self-righteousness to compute such details. Many American cities did defund the police in the face of Floyd riots and after $15 million was deleted from the police budget in Washington DC under useless Woke mayor Muriel Bowser car-jacking alone rose by 300 percent and within six months the US capital recorded its highest murder rate in 15 years. The same happened in Chicago and other cities in line with the Cult/Soros plan to bring fear to streets and neighbourhoods by reducing the police, releasing violent criminals and not prosecuting crime. This is the mob-rule agenda that I have warned in the books was coming for so long. Shootings in the area of Minneapolis where Floyd was arrested increased by 2,500 percent compared with the year before. Defunding the police over George Floyd has led to a big increase in dead people with many of them black. Police protection for politicians making these decisions stayed the same or increased as you would expect from professional hypocrites. The Cult doesn't actually want to abolish the police. It wants to abolish local control over the police and hand it to federal government as the psychopaths advance the Hunger Games Society. Many George Floyd protests turned into violent riots with black stores and businesses destroyed by fire and looting across America fuelled by Black Lives Matter. Woke doesn't do irony. If you want civil rights you must loot the liquor store and the supermarket and make off with a smart TV. It's the only way.

It's not a race war – it's a class war

Black people are patronised by privileged blacks and whites alike and told they are victims of white supremacy. I find it extraordinary to watch privileged blacks supporting the very system and bloodline networks behind the slave trade and parroting the same Cult-serving manipulative crap of their privileged white, often billionaire, associates. It is indeed not a race war but a class war and colour is just a diversion. Black Senator Cory Booker and black Congresswoman Maxine Waters, more residents of Nincompoopia, personify this. Once you tell people they are victims of someone else you devalue both their own responsibility for their plight and the power they have to impact on their reality and experience. Instead we have: ‘You are only in your situation because of whitey – turn on them and everything will change.’ It won’t change. Nothing changes in our lives unless *we* change it. Crucial to that is never seeing yourself as a victim and always as the creator of your reality. Life is a simple sequence of choice and consequence. Make different choices and you create different consequences. *You* have to make those choices – not Black Lives Matter, the Woke Mafia and anyone else that seeks to dictate your life. Who are they these Wokers, an emotional and psychological road traffic accident, to tell you what to do? Personal empowerment is the last thing the Cult and its Black Lives Matter want black people or anyone else to have. They claim to be defending the underdog while *creating* and perpetuating the underdog. The Cult’s worst nightmare is human unity and if they are going to keep blacks, whites and every other race under economic servitude and control then the focus must be diverted from what they have in common to what they can be manipulated to believe divides them. Blacks have to be told that their poverty and plight is the fault of the white bloke living on the street in the same poverty and with the same plight they are experiencing. The difference is that your plight black people is due to him, a white supremacist with ‘white privilege’ living on the street. Don’t unite as one human family against your mutual oppressors and suppressors – fight the oppressor with the white face who is as financially deprived as you are. The Cult knows that as its ‘Covid’ agenda moves into still new levels of extremism people are going to respond and it has been spreading the seeds of disunity everywhere to stop a united response to the evil that targets *all of us*.

Racist attacks on ‘whiteness’ are getting ever more outrageous and especially through the American Democratic Party which has an appalling history for anti-black racism. Barack Obama, Joe Biden, Hillary Clinton and Nancy Pelosi all eulogised about Senator Robert Byrd at his funeral in 2010 after a nearly 60-year career in Congress. Byrd was a brutal Ku Klux Klan racist and a violent abuser of Cathy O’Brien in MKUltra. He said he would never fight in the military ‘with a negro by my side’ and ‘rather I should die a thousand times, and see Old Glory trampled in the dirt never to rise again, than to see this beloved land of ours become degraded by race mongrels, a throwback to the blackest specimen from the wilds'. Biden called Byrd a 'very close friend and mentor'. These 'Woke' hypocrites are not anti-racist they are anti-poor and anti-people not of their perceived class. Here is an illustration of the scale of anti-white racism to which we have now descended. Seriously Woke and moronic *New York Times* contributor Damon Young described whiteness as a 'virus' that 'like other viruses will not die until there are no bodies left for it to infect'. He went on: '… the only way to stop it is to locate it, isolate it, extract it, and kill it.' Young can say that as a black man with no consequences when a white man saying the same in reverse would be facing a jail sentence. *That's* racism. We had super-Woke numbskull senators Tammy Duckworth and Mazie Hirono saying they would object to future Biden Cabinet appointments if he did not nominate more Asian Americans and Pacific Islanders. Never mind the ability of the candidate what do they look like? Duckworth said: 'I will vote for racial minorities and I will vote for LGBTQ, but anyone else I'm not voting for.' Appointing people on the grounds of race is illegal, but that was not a problem for this ludicrous pair. They were on-message and that's a free pass in any situation.

Critical race racism

White children are told at school they are intrinsically racist as they are taught the divisive 'critical race theory'. This claims that the law and legal institutions are inherently racist and that race is a socially constructed concept used by white people to further their economic and political interests at the expense of people of colour. White is a 'virus' as we've seen. Racial inequality results from 'social, economic, and legal differences that white people create between races to maintain white interests which leads to poverty and criminality in minority communities'. I must tell that to the white guy sleeping on the street. The principal of East Side Community School in New York sent white parents a manifesto that called on them to become ‘white traitors’ and advocate for full ‘white abolition’. These people are teaching your kids when they urgently need a psychiatrist. The ‘school’ included a chart with ‘eight white identities’ that ranged from ‘white supremacist’ to ‘white abolition’ and defined the behaviour white people must follow to end ‘the regime of whiteness’. Woke blacks and their privileged white associates are acting exactly like the slave owners of old and Ku Klux Klan racists like Robert Byrd. They are too full of their own self-purity to see that, but it’s true. Racism is not a body type; it’s a state of mind that can manifest through any colour, creed or culture.

Another racial fraud is *‘equity’*. Not equality of treatment and opportunity – equity. It’s a term spun as equality when it means something very different. Equality in its true sense is a raising up while ‘equity’ is a race to the bottom. Everyone in the same level of poverty is ‘equity’. Keep everyone down – that’s equity. The Cult doesn’t want anyone in the human family to be empowered and BLM leaders, like all these ‘anti-racist’ organisations, continue their privileged, pampered existence by perpetuating the perception of gathering racism. When is the last time you heard an ‘anti-racist’ or ‘anti-Semitism’ organisation say that acts of racism and discrimination have *fallen?* It’s not in the interests of their fund-raising and power to influence and the same goes for the professional soccer anti-racism operation, Kick It Out. Two things confirmed that the Black Lives Matter riots in the summer of 2020 were Cult creations. One was that while anti-lockdown protests were condemned in this same period for ‘transmitting ‘Covid’ the authorities supported mass gatherings of Black Lives Matter supporters. I even saw self-deluding people claiming to be doctors say the two types of protest were not the same. No – the non-existent ‘Covid’ was in favour of lockdowns and attacked those that protested against them while ‘Covid’ supported Black Lives Matter and kept well away from its protests. The whole thing was a joke and as lockdown protestors were arrested, often brutally, by reframed Face-Nappies we had the grotesque sight of police officers taking the knee to Black Lives Matter, a Cult-funded Marxist organisation that supports violent riots and wants to destroy the nuclear family and white people.

He's not white? Shucks!

Woke obsession with race was on display again when ten people were shot dead in Boulder, Colorado, in March, 2021. Cult-owned Woke TV channels like CNN said the shooter appeared to be a white man and Wokers were on Twitter condemning 'violent white men' with the usual mantras. Then the shooter's name was released as Ahmad Al Aliwi Alissa, an anti-Trump Arab-American, and the sigh of disappointment could be heard five miles away. Never mind that ten people were dead and what that meant for their families. Race baiting was all that mattered to these sick Cult-serving people like Barack Obama who exploited the deaths to further divide America on racial grounds which is his job for the Cult. This is the man that 'racist' white Americans made the first black president of the United States and then gave him a second term. Not-very-bright Obama has become filthy rich on the back of that and today appears to have a big influence on the Biden administration. Even so he's still a downtrodden black man and a victim of white supremacy. This disingenuous fraud reveals the contempt he has for black people when he puts on a Deep South Alabama accent whenever he talks to them, no, *at* them.

Another BLM red flag was how the now fully-Woke (fully-Cult) and fully-virtue-signalled professional soccer authorities had their teams taking the knee before every match in support of Marxist Black Lives Matter. Soccer authorities and clubs displayed 'Black Lives Matter' on the players' shirts and flashed the name on electronic billboards around the pitch. Any fans that condemned what is a Freemasonic taking-the-knee ritual were widely condemned as you would expect from the Woke virtue-signallers of professional sport and the now fully-Woke media. We have reverse racism in which you are banned from criticising any race or culture except for white people for whom anything goes – say what you like, no problem. What has this got to do with racial harmony and equality? We've had black supremacists from Black Lives Matter telling white people to fall to their knees in the street and apologise for their white supremacy. Black supremacists acting like white supremacist slave owners of the past couldn't breach their self-obsessed, race-obsessed sense of self-purity. Joe Biden appointed a race-obsessed black supremacist Kristen Clarke to head the Justice Department Civil Rights Division. Clarke claimed that blacks are endowed with 'greater mental, physical and spiritual abilities' than whites. If anyone reversed that statement they would be vilified. Clarke is on-message so no problem. She's never seen a black-white situation in which the black figure is anything but a virtuous victim and she heads the Civil Rights Division which should treat everyone the same or it isn't civil rights. Another perception of the Renegade Mind: If something or someone is part of the Cult agenda they will be supported by Woke governments and media no matter what. If they're not, they will be condemned and censored. It really is that simple and so racist Clarke prospers despite (make that because of) her racism.

The end of culture

Biden's administration is full of such racial, cultural and economic bias as the Cult requires the human family to be divided into warring factions. We are now seeing racially-segregated graduations and everything, but everything, is defined through the lens of perceived 'racism. We have 'racist' mathematics, 'racist' food and even 'racist' *plants*. World famous Kew Gardens in London said it was changing labels on plants and flowers to tell its pre-'Covid' more than two million visitors a year how racist they are. Kew director Richard Deverell said this was part of an effort to 'move quickly to decolonise collections' after they were approached by one Ajay Chhabra 'an actor with an insight into how sugar cane was linked to slavery'. They are *plants* you idiots. 'Decolonisation' in the Woke manual really means colonisation of society with its mentality and by extension colonisation by the Cult. We are witnessing a new Chinese-style 'Cultural Revolution' so essential to the success of all

Marxist takeovers. Our cultural past and traditions have to be swept away to allow a new culture to be built-back-better. Woke targeting of long-standing Western cultural pillars including historical monuments and cancelling of historical figures is what happened in the Mao revolution in China which 'purged remnants of capitalist and traditional elements from Chinese society' and installed Maoism as the dominant ideology'. For China see the Western world today and for 'dominant ideology' see Woke. Better still see Marxism or Maoism. The 'Covid' hoax has specifically sought to destroy the arts and all elements of Western culture from people meeting in a pub or restaurant to closing theatres, music venues, sports stadiums, places of worship and even banning *singing*. Destruction of Western society is also why criticism of any religion is banned except for Christianity which again is the dominant religion as white is the numerically-dominant race. Christianity may be fading rapidly, but its history and traditions are weaved through the fabric of Western society. Delete the pillars and other structures will follow until the whole thing collapses. I am not a Christian defending that religion when I say that. I have no religion. It's just a fact. To this end Christianity has itself been turned Woke to usher its own downfall and its ranks are awash with 'change agents' – knowing and unknowing – at every level including Pope Francis (*definitely* knowing) and the clueless Archbishop of Canterbury Justin Welby (possibly not, but who can be sure?). Woke seeks to coordinate attacks on Western culture, traditions, and ways of life through 'intersectionality' defined as 'the complex, cumulative way in which the effects of multiple forms of discrimination (such as racism, sexism, and classism) combine, overlap, or intersect especially in the experiences of marginalised individuals or groups'. Wade through the Orwellian Woke-speak and this means coordinating disparate groups in a common cause to overthrow freedom and liberal values.

The entire structure of public institutions has been infested with Woke – government at all levels, political parties, police, military, schools, universities, advertising, media and trade unions. This abomination has been achieved through the Cult web by appointing

Wokers to positions of power and battering non-Wokers into line through intimidation, isolation and threats to their job. Many have been fired in the wake of the empathy-deleted, vicious hostility of 'social justice' Wokers and the desire of gutless, spineless employers to virtue-signal their Wokeness. Corporations are filled with Wokers today, most notably those in Silicon Valley. Ironically at the top they are not Woke at all. They are only exploiting the mentality their Cult masters have created and funded to censor and enslave while the Wokers cheer them on until it's their turn. Thus the Woke 'liberal left' is an inversion of the traditional liberal left. Campaigning for justice on the grounds of power and wealth distribution has been replaced by campaigning for identity politics. The genuine traditional left would never have taken money from today's billionaire abusers of fairness and justice and nor would the billionaires have wanted to fund that genuine left. It would not have been in their interests to do so. The division of opinion in those days was between the haves and have nots. This all changed with Cult manipulated and funded identity politics. The division of opinion today is between Wokers and non-Wokers and not income brackets. Cult corporations and their billionaires may have taken wealth disparity to cataclysmic levels of injustice, but as long as they speak the language of Woke, hand out the dosh to the Woke network and censor the enemy they are 'one of us'. Billionaires who don't give a damn about injustice are laughing at them till their bellies hurt. Wokers are not even close to self-aware enough to see that. The transformed 'left' dynamic means that Wokers who drone on about 'social justice' are funded by billionaires that have destroyed social justice the world over. It's *why* they are billionaires.

The climate con

Nothing encapsulates what I have said more comprehensively than the hoax of human-caused global warming. I have detailed in my books over the years how Cult operatives and organisations were the pump-primers from the start of the climate con. A purpose-built vehicle for this is the Club of Rome established by the Cult in 1968 with the Rockefellers and Rothschilds centrally involved all along. Their gofer frontman Maurice Strong, a Canadian oil millionaire, hosted the Earth Summit in Rio de Janeiro, Brazil, in 1992 where the global 'green movement' really expanded in earnest under the guiding hand of the Cult. The Earth Summit established Agenda 21 through the Cult-created-and-owned United Nations to use the illusion of human-caused climate change to justify the transformation of global society to save the world from climate disaster. It is a No-Problem-Reaction-Solution sold through governments, media, schools and universities as whole generations have been terrified into believing that the world was going to end in their lifetimes unless what old people had inflicted upon them was stopped by a complete restructuring of how everything is done. Chill, kids, it's all a hoax. Such restructuring is precisely what the Cult agenda demands (purely by coincidence of course). Today this has been given the codename of the Great Reset which is only an updated term for Agenda 21 and its associated Agenda 2030. The latter, too, is administered through the UN and was voted into being by the General Assembly in 2015. Both 21 and 2030 seek centralised control of all resources and food right down to the raindrops falling on your own land. These are some of the demands of Agenda 21 established in 1992. See if you recognise this society emerging today:

- End national sovereignty
- State planning and management of all land resources, ecosystems, deserts, forests, mountains, oceans and fresh water; agriculture; rural development; biotechnology; and ensuring *'equity'*
- The state to 'define the role' of business and financial resources
- Abolition of private property
- 'Restructuring' the family unit (see BLM)
- Children raised by the state
- People told what their job will be
- Major restrictions on movement
- Creation of 'human settlement zones'

- Mass resettlement as people are forced to vacate land where they live
- Dumbing down education
- Mass global depopulation in pursuit of all the above

The United Nations was created as a Trojan horse for world government. With the climate con of critical importance to promoting that outcome you would expect the UN to be involved. Oh, it's involved all right. The UN is promoting Agenda 21 and Agenda 2030 justified by 'climate change' while also driving the climate hoax through its Intergovernmental Panel on Climate Change (IPCC), one of the world's most corrupt organisations. The IPCC has been lying ferociously and constantly since the day it opened its doors with the global media hanging unquestioningly on its every mendacious word. The Green movement is entirely Woke and has long lost its original environmental focus since it was co-opted by the Cult. An obsession with 'global warming' has deleted its values and scrambled its head. I experienced a small example of what I mean on a beautiful country walk that I have enjoyed several times a week for many years. The path merged into the fields and forests and you felt at one with the natural world. Then a 'Green' organisation, the Hampshire and Isle of Wight Wildlife Trust, took over part of the land and proceeded to cut down a large number of trees, including mature ones, to install a horrible big, bright steel 'this-is-ours-stay-out' fence that destroyed the whole atmosphere of this beautiful place. No one with a feel for nature would do that. Day after day I walked to the sound of chainsaws and a magnificent mature weeping willow tree that I so admired was cut down at the base of the trunk. When I challenged a Woke young girl in a green shirt (of course) about this vandalism she replied: 'It's a weeping willow – it will grow back.' This is what people are paying for when they donate to the Hampshire and Isle of Wight Wildlife Trust and many other 'green' organisations today. It is not the environmental movement that I knew and instead has become a support-system – as with Extinction Rebellion – for a very dark agenda.

Private jets for climate justice

The Cult-owned, Gates-funded, World Economic Forum and its founder Klaus Schwab were behind the emergence of Greta Thunberg to harness the young behind the climate agenda and she was invited to speak to the world at … the UN. Schwab published a book, *Covid-19: The Great Reset* in 2020 in which he used the 'Covid' hoax and the climate hoax to lay out a new society straight out of Agenda 21 and Agenda 2030. Bill Gates followed in early 2021 when he took time out from destroying the world to produce a book in his name about the way to save it. Gates flies across the world in private jets and admitted that 'I probably have one of the highest greenhouse gas footprints of anyone on the planet … my personal flying alone is gigantic.' He has also bid for the planet's biggest private jet operator. Other climate change saviours who fly in private jets include John Kerry, the US Special Presidential Envoy for Climate, and actor Leonardo DiCaprio, a 'UN Messenger of Peace with special focus on climate change'. These people are so full of bullshit they could corner the market in manure. We mustn't be sceptical, though, because the Gates book, *How to Avoid a Climate Disaster: The Solutions We Have and the Breakthroughs We Need*, is a genuine attempt to protect the world and not an obvious pile of excrement attributed to a mega-psychopath aimed at selling his masters' plans for humanity. The Gates book and the other shite-pile by Klaus Schwab could have been written by the same person and may well have been. Both use 'climate change' and 'Covid' as the excuses for their new society and by coincidence the Cult's World Economic Forum and Bill and Melinda Gates Foundation promote the climate hoax and hosted Event 201 which pre-empted with a 'simulation' the very 'coronavirus' hoax that would be simulated for real on humanity within weeks. The British 'royal' family is promoting the 'Reset' as you would expect through Prince 'climate change caused the war in Syria' Charles and his hapless son Prince William who said that we must 'reset our relationship with nature and our trajectory as a species' to avoid a climate disaster. Amazing how many promotors of the 'Covid' and 'climate change' control systems are connected to Gates and the World Economic Forum. A 'study' in early 2021 claimed that carbon dioxide emissions must fall by the equivalent of a global lockdown roughly every two years for the next decade to save the planet. The 'study' appeared in the same period that the Schwab mob claimed in a video that lockdowns destroying the lives of billions are good because they make the earth 'quieter' with less 'ambient noise'. They took down the video amid a public backlash for such arrogant, empathy-deleted stupidity You see, however, where they are going with this. Corinne Le Quéré, a professor at the Tyndall Centre for Climate Change Research, University of East Anglia, was lead author of the climate lockdown study, and she writes for … the World Economic Forum. Gates calls in 'his' book for changing 'every aspect of the economy' (long-time Cult agenda) and for humans to eat synthetic 'meat' (predicted in my books) while cows and other farm animals are eliminated. Australian TV host and commentator Alan Jones described what carbon emission targets would mean for farm animals in Australia alone if emissions were reduced as demanded by 35 percent by 2030 and zero by 2050:

> Well, let's take agriculture, the total emissions from agriculture are about 75 million tonnes of carbon dioxide, equivalent. Now reduce that by 35 percent and you have to come down to 50 million tonnes, I've done the maths. So if you take for example 1.5 million cows, you're going to have to reduce the herd by 525,000 [by] 2030, nine years, that's 58,000 cows a year. The beef herd's 30 million, reduce that by 35 percent, that's 10.5 million, which means 1.2 million cattle have to go every year between now and 2030. This is insanity!
>
> There are 75 million sheep. Reduce that by 35 percent, that's 26 million sheep, that's almost 3 million a year. So under the Paris Agreement over 30 million beasts. dairy cows, cattle, pigs and sheep would go. More than 8,000 every minute of every hour for the next decade, do these people know what they're talking about?

Clearly they don't at the level of campaigners, politicians and administrators. The Cult *does* know; that's the outcome it wants. We are faced with not just a war on humanity. Animals and the natural world are being targeted and I have been saying since the 'Covid' hoax began that the plan eventually was to claim that the 'deadly virus' is able to jump from animals, including farm animals and domestic pets, to humans. Just before this book went into production came this story: ‘Russia registers world’s first Covid-19 vaccine for cats & dogs as makers of Sputnik V warn pets & farm animals could spread virus’. The report said ‘top scientists warned that the deadly pathogen could soon begin spreading through homes and farms’ and ‘the next stage is the infection of farm and domestic animals’. Know the outcome and you’ll see the journey. Think what that would mean for animals and keep your eye on a term called zoonosis or zoonotic diseases which transmit between animals and humans. The Cult wants to break the connection between animals and people as it does between people and people. Farm animals fit with the Cult agenda to transform food from natural to synthetic.

The gas of life is killing us

There can be few greater examples of Cult inversion than the condemnation of carbon dioxide as a dangerous pollutant when it is the gas of life. Without it the natural world would be dead and so we would all be dead. We breathe in oxygen and breathe out carbon dioxide while plants produce oxygen and absorb carbon dioxide. It is a perfect symbiotic relationship that the Cult wants to dismantle for reasons I will come to in the final two chapters. Gates, Schwab, other Cult operatives and mindless repeaters, want the world to be ‘carbon neutral’ by at least 2050 and the earlier the better. ‘Zero carbon’ is the cry echoed by lunatics calling for ‘Zero Covid’ when we already have it. These carbon emission targets will deindustrialise the world in accordance with Cult plans – the post-industrial, post-democratic society – and with so-called renewables like solar and wind not coming even close to meeting human energy needs blackouts and cold are inevitable. Texans got the picture in the winter of 2021 when a snow storm stopped wind turbines and solar panels from working and the lights went down along with water which relies on electricity for its supply system. Gates wants everything to be powered by electricity to ensure that his masters have the kill switch to stop all human activity, movement, cooking, water and warmth any time they like. The climate lie is so stupendously inverted that it claims we must urgently reduce carbon dioxide when we *don't have enough*.

Co2 in the atmosphere is a little above 400 parts per million when the optimum for plant growth is 2,000 ppm and when it falls anywhere near 150 ppm the natural world starts to die and so do we. It fell to as low as 280 ppm in an 1880 measurement in Hawaii and rose to 413 ppm in 2019 with industrialisation which is why the planet has become *greener* in the industrial period. How insane then that psychopathic madman Gates is not satisfied only with blocking the rise of Co2. He's funding technology to suck it out of the atmosphere. The reason why will become clear. The industrial era is not destroying the world through Co2 and has instead turned around a potentially disastrous ongoing fall in Co2. Greenpeace co-founder and scientist Patrick Moore walked away from Greenpeace in 1986 and has exposed the green movement for fear-mongering and lies. He said that 500 million years ago there was *17 times* more Co2 in the atmosphere than we have today and levels have been falling for hundreds of millions of years. In the last 150 million years Co2 levels in Earth's atmosphere had reduced by *90 percent*. Moore said that by the time humanity began to unlock carbon dioxide from fossil fuels we were at '38 seconds to midnight' and in that sense: 'Humans are [the Earth's] salvation.' Moore made the point that only half the Co2 emitted by fossil fuels stays in the atmosphere and we should remember that all pollution pouring from chimneys that we are told is carbon dioxide is in fact nothing of the kind. It's pollution. Carbon dioxide is an invisible gas.

William Happer, Professor of Physics at Princeton University and long-time government adviser on climate, has emphasised the Co2 deficiency for maximum growth and food production. Greenhouse growers don't add carbon dioxide for a bit of fun. He said that most of the warming in the last 100 years, after the earth emerged from the super-cold period of the 'Little Ice Age' into a natural warming cycle, was over by 1940. Happer said that a peak year for warming in 1988 can be explained by a 'monster El Nino' which is a natural and cyclical warming of the Pacific that has nothing to do with 'climate change'. He said the effect of Co2 could be compared to painting a wall with red paint in that once two or three coats have been applied it didn't matter how much more you slapped on because the wall will not get much redder. Almost all the effect of the rise in Co2 has already happened, he said, and the volume in the atmosphere would now have to *double* to increase temperature by a single degree. Climate hoaxers know this and they have invented the most ridiculously complicated series of 'feedback' loops to try to overcome this rather devastating fact. You hear puppet Greta going on cluelessly about feedback loops and this is why.

The Sun affects temperature? No you *climate denier*

Some other nonsense to contemplate: Climate graphs show that rises in temperature do not follow rises in Co2 – *it's the other way round* with a lag between the two of some 800 years. If we go back 800 years from present time we hit the Medieval Warm Period when temperatures were higher than now without any industrialisation and this was followed by the Little Ice Age when temperatures plummeted. The world was still emerging from these centuries of serious cold when many climate records began which makes the ever-repeated line of the 'hottest year since records began' meaningless when you are not comparing like with like. The coldest period of the Little Ice Age corresponded with the lowest period of sunspot activity when the Sun was at its least active. Proper scientists will not be at all surprised by this when it confirms the obvious fact that earth temperature is affected by the scale of Sun activity and the energetic power that it subsequently emits; but when is the last time you heard a climate hoaxer talking about the Sun as a source of earth temperature?? Everything has to be focussed on Co2 which makes up just 0.117 percent of so-called greenhouse gases and only a fraction of even that is generated by human activity. The rest is natural. More than *90 percent* of those greenhouse gases are water vapour and clouds (Fig 9). Ban moisture I say. Have you noticed that the climate hoaxers no longer use the polar bear as their promotion image? That's because far from becoming extinct polar bear communities are stable or thriving. Joe Bastardi, American meteorologist, weather forecaster and outspoken critic of the climate lie, documents in his book *The Climate Chronicles* how weather patterns and events claimed to be evidence of climate change have been happening since long before industrialisation: 'What happened before naturally is happening again, as is to be expected given the cyclical nature of the climate due to the design of the planet.' If you read the detailed background to the climate hoax in my other books you will shake your head and wonder how anyone could believe the crap which has spawned a multi-trillion dollar industry based on absolute garbage (see HIV causes AIDs and Sars-Cov-2 causes 'Covid-19'). Climate and 'Covid' have much in common given they have the same source. They both have the contradictory *everything* factor in which everything is explained by reference to them. It's hot – 'it's climate change'. It's cold – 'it's climate change'. I got a sniffle – 'it's Covid'. I haven't got a sniffle – 'it's Covid'. Not having a sniffle has to be a symptom of 'Covid'. Everything is and not having a sniffle is especially dangerous if you are a slow walker. For sheer audacity I offer you a Cambridge University 'study' that actually linked 'Covid' to 'climate change'. It had to happen eventually. They concluded that climate change played a role in 'Covid-19' spreading from animals to humans because … wait for it … I kid you not … *the two groups were forced closer together as populations grow*. Er, that's it. The whole foundation on which this depended was that 'Bats are the likely zoonotic origin of SARS-CoV-1 and SARS-CoV-2'. Well, they are not. They are nothing to do with it. Apart from bats not being the origin and therefore 'climate change' effects on bats being irrelevant I am in awe of their academic insight. Where would we be without them? Not where we are that's for sure.

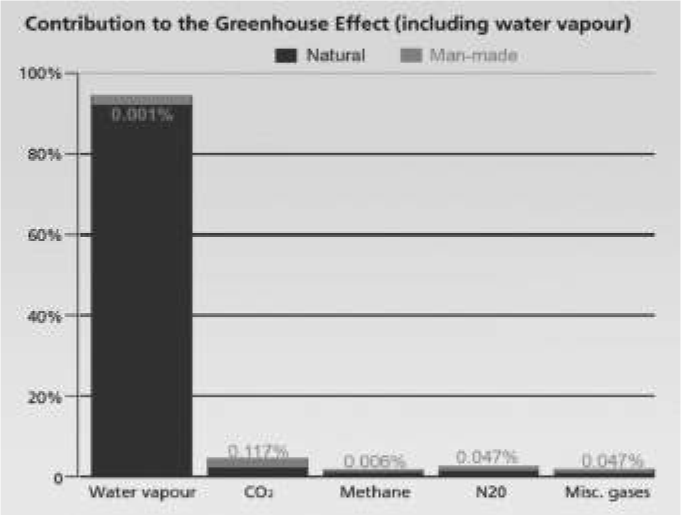

Figure 9: The idea that the gas of life is disastrously changing the climate is an insult to brain cell activity.

One other point about the weather is that climate modification is now well advanced and not every major weather event is natural – or earthquake come to that. I cover this subject at some length in other books. China is openly planning a rapid expansion of its weather modification programme which includes changing the climate in an area more than one and a half times the size of India. China used weather manipulation to ensure clear skies during the 2008 Olympics in Beijing. I have quoted from US military documents detailing how to employ weather manipulation as a weapon of war and they did that in the 1960s and 70s during the conflict in Vietnam with Operation Popeye manipulating monsoon rains for military purposes. Why would there be international treaties on weather modification if it wasn't possible? Of course it is. Weather is energetic information and it can be changed.

How was the climate hoax pulled off? See 'Covid'

If you can get billions to believe in a 'virus' that doesn't exist you can get them to believe in human-caused climate change that doesn't exist. Both are being used by the Cult to transform global society in the way it has long planned. Both hoaxes have been achieved in pretty much the same way. First you declare a lie is a fact. There's a ‘virus’ you call SARS-Cov-2 or humans are warming the planet with their behaviour. Next this becomes, via Cult networks, the foundation of government, academic and science policy and belief. Those who parrot the mantra are given big grants to produce research that confirms the narrative is true and ever more ‘symptoms’ are added to make the ‘virus’/’climate change’ sound even more scary. Scientists and researchers who challenge the narrative have their grants withdrawn and their careers destroyed. The media promote the lie as the unquestionable truth and censor those with an alternative view or evidence. A great percentage of the population believe what they are told as the lie becomes an everybody-knows-that and the believing-masses turn on those with a mind of their own. The technique has been used endlessly throughout human history. Wokers are the biggest promotors of the climate lie *and* ‘Covid’ fascism because their minds are owned by the Cult; their sense of self-righteous self-purity knows no bounds; and they exist in a bubble of reality in which facts are irrelevant and only get in the way of looking without seeing.

Running through all of this like veins in a blue cheese is control of information, which means control of perception, which means control of behaviour, which collectively means control of human society. The Cult owns the global media and Silicon Valley fascists for the simple reason that it *has* to. Without control of information it can’t control perception and through that human society. Examine every facet of the Cult agenda and you will see that anything supporting its introduction is never censored while anything pushing back is always censored. I say again: Psychopaths that know why they are doing this must go before Nuremberg trials and those that follow their orders must trot along behind them into the same dock. ‘I was just following orders’ didn’t work the first time and it must not work now. Nuremberg trials must be held all over the world before public juries for politicians, government officials, police, compliant doctors, scientists and virologists, and all Cult operatives such as Gates, Tedros, Fauci, Vallance, Whitty, Ferguson, Zuckerberg, Wojcicki, Brin, Page, Dorsey, the whole damn lot of them – including, no *especially*, the psychopath psychologists. Without them and the brainless, gutless excuses for journalists that have repeated their lies, none of this could be happening. Nobody can be allowed to escape justice for the psychological and economic Armageddon they are all responsible for visiting upon the human race.

As for the compliant, unquestioning, swathes of humanity, and the self-obsessed, all-knowing ignorance of the Wokers … don’t start me. God help their kids. God help their grandkids. God *help them*.

CHAPTER NINE

We must have it? So what is it?

Well I won't back down. No, I won't back down. You can stand me up at the Gates of Hell. But I won't back down
Tom Petty

I will now focus on the genetically-manipulating 'Covid vaccines' which do not meet this official definition of a vaccine by the US Centers for Disease Control (CDC): 'A product that stimulates a person's immune system to produce immunity to a specific disease, protecting the person from that disease.' On that basis 'Covid vaccines' are not a vaccine in that the makers don't even claim they stop infection or transmission.

They are instead part of a multi-levelled conspiracy to change the nature of the human body and what it means to be 'human' and to depopulate an enormous swathe of humanity. What I shall call Human 1.0 is on the cusp of becoming Human 2.0 and for very sinister reasons. Before I get to the 'Covid vaccine' in detail here's some background to vaccines in general. Government regulators do not test vaccines – the makers do – and the makers control which data is revealed and which isn't. Children in America are given 50 vaccine doses by age six and 69 by age 19 and the effect of the whole combined schedule has never been tested. Autoimmune diseases when the immune system attacks its own body have soared in the mass vaccine era and so has disease in general in children and the young. Why wouldn't this be the case when vaccines target the *immune system?* The US government gave Big Pharma drug companies immunity from prosecution for vaccine death and injury in the 1986 National Childhood Vaccine Injury Act (NCVIA) and since then the government (taxpayer) has been funding compensation for the consequences of Big Pharma vaccines. The criminal and satanic drug giants can't lose and the vaccine schedule has increased dramatically since 1986 for this reason. There is no incentive to make vaccines safe and a big incentive to make money by introducing ever more. Even against a ridiculously high bar to prove vaccine liability, and with the government controlling the hearing in which it is being challenged for compensation, the vaccine court has so far paid out more than $4 billion. These are the vaccines we are told are safe and psychopaths like Zuckerberg censor posts saying otherwise. The immunity law was even justified by a ruling that vaccines by their nature were 'unavoidably unsafe'.

Check out the ingredients of vaccines and you will be shocked if you are new to this. *They put that in children's bodies?? What??* Try aluminium, a brain toxin connected to dementia, aborted foetal tissue and formaldehyde which is used to embalm corpses. World-renowned aluminium expert Christopher Exley had his research into the health effect of aluminium in vaccines shut down by Keele University in the UK when it began taking funding from the Bill and Melinda Gates Foundation. Research when diseases 'eradicated' by vaccines began to decline and you will find the fall began long *before* the vaccine was introduced. Sometimes the fall even plateaued after the vaccine. Diseases like scarlet fever for which there was no vaccine declined in the same way because of environmental and other factors. A perfect case in point is the polio vaccine. Polio began when lead arsenate was first sprayed as an insecticide and residues remained in food products. Spraying started in 1892 and the first US polio epidemic came in Vermont in 1894. The simple answer was to stop spraying, but Rockefeller-created Big Pharma had a better idea. Polio was decreed to be caused by the *poliovirus* which 'spreads from person to person and can infect a person's spinal cord'. Lead arsenate was replaced by the lethal DDT which had the same effect of causing paralysis by damaging the brain and central nervous system. Polio plummeted when DDT was reduced and then banned, but the vaccine is still given the credit for something it didn't do. Today by far the biggest cause of polio is the vaccines promoted by Bill Gates. Vaccine justice campaigner Robert Kennedy Jr, son of assassinated (by the Cult) US Attorney General Robert Kennedy, wrote:

> In 2017, the World Health Organization (WHO) reluctantly admitted that the global explosion in polio is predominantly vaccine strain. The most frightening epidemics in Congo, Afghanistan, and the Philippines, are all linked to vaccines. In fact, by 2018, 70% of global polio cases were vaccine strain.

Vaccines make fortunes for Cult-owned Gates and Big Pharma while undermining the health and immune systems of the population. We had a glimpse of the mentality behind the Big Pharma cartel with a report on WION (World is One News), an international English language TV station based in India, which exposed the extraordinary behaviour of US drug company Pfizer over its 'Covid vaccine'. The WION report told how Pfizer had made fantastic demands of Argentina, Brazil and other countries in return for its 'vaccine'. These included immunity from prosecution, even for Pfizer negligence, government insurance to protect Pfizer from law suits and handing over as collateral sovereign assets of the country to include Argentina's bank reserves, military bases and embassy buildings. Pfizer demanded the same of Brazil in the form of waiving sovereignty of its assets abroad; exempting Pfizer from Brazilian laws; and giving Pfizer immunity from all civil liability. This is a 'vaccine' developed with government funding. Big Pharma is evil incarnate as a creation of the Cult and all must be handed tickets to Nuremberg.

Phantom 'vaccine' for a phantom 'disease'

I'll expose the 'Covid vaccine' fraud and then go on to the wider background of why the Cult has set out to 'vaccinate' every man, woman and child on the planet for an alleged 'new disease' with a survival rate of 99.77 percent (or more) even by the grotesquelymanipulated figures of the World Health Organization and Johns Hopkins University. The ‘infection’ to ‘death’ ratio is 0.23 to 0.15 percent according to Stanford epidemiologist Dr John Ioannidis and while estimates vary the danger remains tiny. I say that if the truth be told the fake infection to fake death ratio is zero. Never mind all the evidence I have presented here and in *The Answer* that there is no ‘virus’ let us just focus for a moment on that death-rate figure of say 0.23 percent. The figure includes all those worldwide who have tested positive with a test not testing for the ‘virus’ and then died within 28 days or even longer of any other cause – *any other cause*. Now subtract all those illusory ‘Covid’ deaths on the global data sheets from the 0.23 percent. What do you think you would be left with? *Zero*. A vaccination has never been successfully developed for a so-called coronavirus. They have all failed at the animal testing stage when they caused hypersensitivity to what they were claiming to protect against and made the impact of a disease far worse. Cult-owned vaccine corporations got around that problem this time by bypassing animal trials, going straight to humans and making the length of the ‘trials’ before the public rollout as short as they could get away with. Normally it takes five to ten years or more to develop vaccines that still cause demonstrable harm to many people and that’s without including the long-term effects that are never officially connected to the vaccination. ‘Covid’ non-vaccines have been officially produced and approved in a matter of months from a standing start and part of the reason is that (a) they were developed before the ‘Covid’ hoax began and (b) they are based on computer programs and not natural sources. Official non-trials were so short that government agencies gave *emergency*, not full, approval. ‘Trials’ were not even completed and full approval cannot be secured until they are. Public ‘Covid vaccination’ is actually a *continuation of the trial*. Drug company ‘trials’ are not scheduled to end until 2023 by which time a lot of people are going to be dead. Data on which government agencies gave this emergency approval was supplied by the Big Pharma corporations themselves in the form of Pfizer/BioNTech, AstraZeneca, Moderna, Johnson & Johnson, and others, and this is the case with all vaccines. By its very nature *emergency* approval means drug companies do not have to prove that the 'vaccine' is 'safe and effective'. How could they with trials way short of complete? Government regulators only have to *believe* that they *could* be safe and effective. It is criminal manipulation to get products in circulation with no testing worth the name. Agencies giving that approval are infested with Big Pharma-connected place-people and they act in the interests of Big Pharma (the Cult) and not the public about whom they do not give a damn.

More human lab rats

'Covid vaccines' produced in record time by Pfizer/BioNTech and Moderna employ a technique *never approved before for use on humans*. They are known as mRNA 'vaccines' and inject a synthetic version of 'viral' mRNA or 'messenger RNA'. The key is in the term 'messenger'. The body works, or doesn't, on the basis of information messaging. Communications are constantly passing between and within the genetic system and the brain. Change those messages and you change the state of the body and even its very nature and you can change psychology and behaviour by the way the brain processes information. I think you are going to see significant changes in personality and perception of many people who have had the 'Covid vaccine' synthetic potions. Insider Aldous Huxley predicted the following in 1961 and mRNA 'vaccines' can be included in the term 'pharmacological methods':

> There will be, in the next generation or so, a pharmacological method of making people love their servitude, and producing dictatorship without tears, so to speak, producing a kind of painless concentration camp for entire societies, so that people will in fact have their own liberties taken away from them, but rather enjoy it, because they will be distracted from any desire to rebel by propaganda or brainwashing, or brainwashing enhanced by pharmacological methods. And this seems to be the final revolution.

Apologists claim that mRNA synthetic 'vaccines' don't change the DNA genetic blueprint because RNA does not affect DNA only the other way round. This is so disingenuous. A process called 'reverse transcription' can convert RNA into DNA and be integrated into DNA in the cell nucleus. This was highlighted in December, 2020, by scientists at Harvard and Massachusetts Institute of Technology (MIT). Geneticists report that more than 40 percent of mammalian genomes results from reverse transcription. On the most basic level if messaging changes then that sequence must lead to changes in DNA which is receiving and transmitting those communications. How can introducing synthetic material into cells not change the cells where DNA is located? The process is known as transfection which is defined as 'a technique to insert foreign nucleic acid (DNA or RNA) into a cell, typically with the intention of altering the properties of the cell'. Researchers at the Sloan Kettering Institute in New York found that changes in messenger RNA can deactivate tumour-suppressing proteins and thereby promote cancer. This is what happens when you mess with messaging. 'Covid vaccine' maker Moderna was founded in 2010 by Canadian stem cell biologist Derrick J. Rossi after his breakthrough discovery in the field of transforming and reprogramming stem cells. These are neutral cells that can be programmed to become any cell including sperm cells. Moderna was therefore founded on the principle of genetic manipulation and has never produced any vaccine or drug before its genetically-manipulating synthetic 'Covid' shite. Look at the name – Mode-RNA or Modify-RNA. Another important point is that the US Supreme Court has ruled that genetically-modified DNA, or complementary DNA (cDNA) synthesized in the laboratory from messenger RNA, can be patented and owned. These psychopaths are doing this to the human body.

Cells replicate synthetic mRNA in the 'Covid vaccines' and in theory the body is tricked into making antigens which trigger antibodies to target the 'virus spike proteins' which as Dr Tom Cowan said have *never been seen*. Cut the crap and these 'vaccines' deliver *self-replicating* synthetic material to the cells with the effect of changing human DNA. The more of them you have the more that process is compounded while synthetic material is all the time self-replicating. 'Vaccine'-maker Moderna describes mRNA as 'like software for the cell' and so they are messing with the body's software. What happens when you change the software in a computer? Everything changes. For this reason the Cult is preparing a production line of mRNA 'Covid vaccines' and a long list of excuses to use them as with all the 'variants' of a 'virus' never shown to exist. The plan is further to transfer the mRNA technique to other vaccines mostly given to children and young people. The cumulative consequences will be a transformation of human DNA through a constant infusion of synthetic genetic material which will kill many and change the rest. Now consider that governments that have given emergency approval for a vaccine that's not a vaccine; never been approved for humans before; had no testing worth the name; and the makers have been given immunity from prosecution for any deaths or adverse effects suffered by the public. The UK government awarded *permanent legal indemnity* to itself and its employees for harm done when a patient is being treated for 'Covid-19' or 'suspected Covid-19'. That is quite a thought when these are possible 'side-effects' from the 'vaccine' (they are not 'side', they are effects) listed by the US Food and Drug Administration:

Guillain-Barre syndrome; acute disseminated encephalomyelitis; transverse myelitis; encephalitis; myelitis; encephalomyelitis; meningoencephalitis; meningitis; encephalopathy; convulsions; seizures; stroke; narcolepsy; cataplexy; anaphylaxis; acute myocardial infarction (heart attack); myocarditis; pericarditis; autoimmune disease; death; implications for pregnancy, and birth outcomes; other acute demyelinating diseases; non anaphylactic allergy reactions; thrombocytopenia ; disseminated intravascular coagulation; venous thromboembolism; arthritis; arthralgia; joint pain; Kawasaki disease; multisystem inflammatory syndrome in children; vaccine enhanced disease. The latter is the way the 'vaccine' has the potential to make diseases far worse than they would otherwise be.

UK doctor and freedom campaigner Vernon Coleman described the conditions in this list as 'all unpleasant, most of them very serious, and you can't get more serious than death'. The thought that anyone at all has had the 'vaccine' in these circumstances is testament to the potential that humanity has for clueless, unquestioning, stupidity and for many that programmed stupidity has already been terminal.

An insider speaks

Dr Michael Yeadon is a former Vice President, head of research and Chief Scientific Adviser at vaccine giant Pfizer. Yeadon worked on the inside of Big Pharma, but that did not stop him becoming a vocal critic of 'Covid vaccines' and their potential for multiple harms, including infertility in women. By the spring of 2021 he went much further and even used the no, no, term 'conspiracy'. When you begin to see what is going on it is impossible not to do so. Yeadon spoke out in an interview with freedom campaigner James Delingpole and I mentioned earlier how he said that no one had samples of 'the virus'. He explained that the mRNA technique originated in the anti-cancer field and ways to turn on and off certain genes which could be advantageous if you wanted to stop cancer growing out of control. 'That's the origin of them. They are a very unusual application, really.' Yeadon said that treating a cancer patient with an aggressive procedure might be understandable if the alternative was dying, but it was quite another thing to use the same technique as a public health measure. Most people involved wouldn't catch the infectious agent you were vaccinating against and if they did they probably wouldn't die:

> If you are really using it as a public health measure you really want to as close as you can get to zero sides-effects … I find it odd that they chose techniques that were really cutting their teeth in the field of oncology and I'm worried that in using gene-based vaccines that have to be injected in the body and spread around the body, get taken up into some cells, and the regulators haven't quite told us which cells they get taken up into … you are going to be generating a wide range of responses … with multiple steps each of which could go well or badly.

I doubt the Cult intends it to go well. Yeadon said that you can put any gene you like into the body through the 'vaccine'. 'You can certainly give them a gene that would do them some harm if you wanted.' I was intrigued when he said that when used in the cancer field the technique could turn genes on and off. I explore this process in *The Answer* and with different genes having different functions you could create mayhem – physically and psychologically – if you turned the wrong ones on and the right ones off. I read reports of an experiment by researchers at the University of Washington's school of computer science and engineering in which they encoded DNA to infect computers. The body is itself a biological computer and if human DNA can inflict damage on a computer why can't the computer via synthetic material mess with the human body? It can. The Washington research team said it was possible to insert malicious malware into 'physical DNA strands' and corrupt the computer system of a gene sequencing machine as it 'reads gene letters and stores them as binary digits 0 and 1'. They concluded that hackers could one day use blood or spit samples to access computer systems and obtain sensitive data from police forensics labs or infect genome files. It is at this level of digital interaction that synthetic 'vaccines' need to be seen to get the full picture and that will become very clear later on. Michael Yeadon said it made no sense to give the 'vaccine' to younger people who were in no danger from the 'virus'. What was the benefit? It was all downside with potential effects:

> The fact that my government in what I thought was a civilised, rational country, is raining [the 'vaccine'] on people in their 30s and 40s, even my children in their 20s, they're getting letters and phone calls, I know this is not right and any of you doctors who are vaccinating you know it's not right, too. They are not at risk. They are not at risk from the disease, so you are now hoping that the side-effects are so rare that you get away with it. You don't give new technology … that you don't understand to 100 percent of the population.

Blood clot problems with the AstraZeneca 'vaccine' have been affecting younger people to emphasise the downside risks with no benefit. AstraZeneca's version, produced with Oxford University, does not use mRNA, but still gets its toxic cocktail inside cells where it targets DNA. The Johnson & Johnson 'vaccine' which uses a similar technique has also produced blood clot effects to such an extent that the United States paused its use at one point. They are all 'gene therapy' (cell modification) procedures and not 'vaccines'. The truth is that once the content of these injections enter cells we have no idea what the effect will be. People can speculate and some can give very educated opinions and that's good. In the end, though, only the makers know what their potions are designed to do and even they won't know every last consequence. Michael Yeadon was scathing about doctors doing what they knew to be wrong. 'Everyone's mute', he said. Doctors in the NHS must know this was not right, coming into work and injecting people. 'I don't know how they sleep at night. I know I couldn't do it. I know that if I were in that position I'd have to quit.' He said he knew enough about toxicology to know this was not a good risk-benefit. Yeadon had spoken to seven or eight university professors and all except two would not speak out publicly. Their universities had a policy that no one said anything that countered the government and its medical advisors. They were afraid of losing their government grants. This is how intimidation has been used to silence the truth at every level of the system. I say silence, but these people could still speak out if they made that choice. Yeadon called them 'moral cowards' – 'This is about your children and grandchildren's lives and you have just buggered off and left it.'

'Variant' nonsense

Some of his most powerful comments related to the alleged 'variants' being used to instil more fear, justify more lockdowns, and introduce more 'vaccines'. He said government claims about 'variants' were nonsense. He had checked the alleged variant 'codes' and they were 99.7 percent identical to the 'original'. This was the human identity difference equivalent to putting a baseball cap on and off or wearing it the other way round. A 0.3 percent difference would make it impossible for that 'variant' to escape immunity from the 'original'. This made no sense of having new 'vaccines' for ‘variants’. He said there would have to be at least a *30 percent* difference for that to be justified and even then he believed the immune system would still recognise what it was. Gates-funded ‘variant modeller’ and ‘vaccine’-pusher John Edmunds might care to comment. Yeadon said drug companies were making new versions of the ‘vaccine’ as a ‘top up’ for ‘variants’. Worse than that, he said, the ‘regulators’ around the world like the MHRA in the UK had got together and agreed that because ‘vaccines’ for ‘variants’ were so similar to the first ‘vaccines’ *they did not have to do safety studies*. How transparently sinister that is. This is when Yeadon said: ‘There is a conspiracy here.’ There was no need for another vaccine for ‘variants’ and yet we were told that there was and the country had shut its borders because of them. ‘They are going into hundreds of millions of arms without passing ‘go’ or any regulator. Why did they do that? Why did they pick this method of making the vaccine?’

The reason had to be something bigger than that it seemed and ‘it’s not protection against the virus’. It’s was a far bigger project that meant politicians and advisers were willing to do things and not do things that knowingly resulted in avoidable deaths – ‘that’s already happened when you think about lockdown and deprivation of health care for a year.’ He spoke of people prepared to do something that results in the avoidable death of their fellow human beings and it not bother them. This is the penny-drop I have been working to get across for more than 30 years – the level of pure evil we are dealing with. Yeadon said his friends and associates could not believe there could be that much evil, but he reminded them of Stalin, Pol Pot and Hitler and of what Stalin had said: ‘One death is a tragedy. A million? A statistic.’ He could not think of a benign explanation for why you need top-up vaccines ‘which I’m sure you don’t’ and for the regulators ‘to just get out of the way and wave them through’. Why would the regulators do that when they were still wrestling with the dangers of the ‘parent’ vaccine? He was clearly shocked by what he had seen since the ‘Covid’ hoax began and now he was thinking the previously unthinkable:

> If you wanted to depopulate a significant proportion of the world and to do it in a way that doesn't involve destruction of the environment with nuclear weapons, poisoning everyone with anthrax or something like that, and you wanted plausible deniability while you had a multi-year infectious disease crisis, I actually don't think you could come up with a better plan of work than seems to be in front of me. I can't say that's what they are going to do, but I can't think of a benign explanation why they are doing it.

He said he never thought that they would get rid of 99 percent of humans, but now he wondered. 'If you wanted to that this would be a hell of a way to do it – it would be unstoppable folks.' Yeadon had concluded that those who submitted to the 'vaccine' would be allowed to have some kind of normal life (but for how long?) while screws were tightened to coerce and mandate the last few percent. 'I think they'll put the rest of them in a prison camp. I wish I was wrong, but I don't think I am.' Other points he made included: There were no coronavirus vaccines then suddenly they all come along at the same time; we have no idea of the long term affect with trials so short; coercing or forcing people to have medical procedures is against the Nuremberg Code instigated when the Nazis did just that; people should at least delay having the 'vaccine'; a quick Internet search confirms that masks don't reduce respiratory viral transmission and 'the government knows that'; they have smashed civil society and they know that, too; two dozen peer-reviewed studies show no connection between lockdown and reducing deaths; he knew from personal friends the elite were still flying around and going on holiday while the public were locked down; the elite were not having the 'vaccines'. He was also asked if 'vaccines' could be made to target difference races. He said he didn't know, but the document by the Project for the New American Century in September, 2000, said developing 'advanced forms of biological warfare that can target *specific genotypes* may transform biological warfare from the realm of terror to a politically useful tool.' Oh, they're evil all right. Of that we can be *absolutely* sure.

Another cull of old people

We have seen from the CDC definition that the mRNA 'Covid vaccine' is not a vaccine and nor are the others that *claim* to reduce 'severity of symptoms' in *some* people, but not protect from infection or transmission. What about all the lies about returning to 'normal' if people were 'vaccinated'? If they are not claimed to stop infection and transmission of the alleged 'virus', how does anything change? This was all lies to manipulate people to take the jabs and we are seeing that now with masks and distancing still required for the 'vaccinated'. How did they think that elderly people with fragile health and immune responses were going to be affected by infusing their cells with synthetic material and other toxic substances? They *knew* that in the short and long term it would be devastating and fatal as the culling of the old that began with the first lockdowns was continued with the 'vaccine'. Death rates in care homes soared immediately residents began to be 'vaccinated' – infused with synthetic material. Brave and committed whistleblower nurses put their careers at risk by exposing this truth while the rest kept their heads down and their mouths shut to put their careers before those they are supposed to care for. A long-time American Certified Nursing Assistant who gave his name as James posted a video in which he described emotionally what happened in his care home when vaccination began. He said that during 2020 very few residents were sick with 'Covid' and no one died during the entire year; but shortly after the Pfizer mRNA injections 14 people died within two weeks and many others were near death. 'They're dropping like flies', he said. Residents who walked on their own before the shot could no longer and they had lost their ability to conduct an intelligent conversation. The home's management said the sudden deaths were caused by a 'super-spreader' of 'Covid-19'. Then how come, James asked, that residents who refused to take the injections were not sick? It was a case of inject the elderly with mRNA synthetic potions and blame their illness and death that followed on the 'virus'. James described what was happening in care homes as 'the greatest crime of genocide this country has ever seen'. Remember the NHS staff nurse from earlier who used the same word ‘genocide’ for what was happening with the ‘vaccines’ and that it was an ‘act of human annihilation’. A UK care home whistleblower told a similar story to James about the effect of the ‘vaccine’ in deaths and ‘outbreaks’ of illness dubbed ‘Covid’ after getting the jab. She told how her care home management and staff had zealously imposed government regulations and no one was allowed to even question the official narrative let alone speak out against it. She said the NHS was even worse. Again we see the results of reframing. A worker at a local care home where I live said they had not had a single case of ‘Covid’ there for almost a year and when the residents were ‘vaccinated’ they had 19 positive cases in two weeks with eight dying.

It’s not the ‘vaccine’ – honest

The obvious cause and effect was being ignored by the media and most of the public. Australia’s health minister Greg Hunt (a former head of strategy at the World Economic Forum) was admitted to hospital after he had the ‘vaccine’. He was suffering according to reports from the skin infection ‘cellulitis’ and it must have been a severe case to have warranted days in hospital. Immediately the authorities said this was nothing to do with the ‘vaccine’ when an effect of some vaccines is a ‘cellulitis-like reaction’. We had families of perfectly healthy old people who died after the ‘vaccine’ saying that if only they had been given the ‘vaccine’ earlier they would still be alive. As a numbskull rating that is off the chart. A father of four ‘died of Covid’ at aged 48 when he was taken ill two days after having the ‘vaccine’. The man, a health administrator, had been ‘shielding during the pandemic’ and had ‘not really left the house’ until he went for the ‘vaccine’. Having the ‘vaccine’ and then falling ill and dying does not seem to have qualified as a possible cause and effect and ‘Covid-19’ went on his death certificate. His family said they had no idea how he ‘caught the virus’. A family member said: ‘Tragically, it could be that going for a vaccination ultimately led to him catching Covid …The sad truth is that they are never going to know where it came from.’ The family warned people to remember that the virus still existed and was ‘very real’. So was their stupidity. Nurses and doctors who had the first round of the ‘vaccine’ were collapsing, dying and ending up in a hospital bed while they or their grieving relatives were saying they’d still have the ‘vaccine’ again despite what happened. I kid you not. You mean if your husband returned from the dead he’d have the same ‘vaccine’ again that killed him??

Doctors at the VCU Medical Center in Richmond, Virginia, said the Johnson & Johnson ‘vaccine’ was to blame for a man’s skin peeling off. Patient Richard Terrell said: ‘It all just happened so fast. My skin peeled off. It’s still coming off on my hands now.’ He said it was stinging, burning and itching and when he bent his arms and legs it was very painful with ‘the skin swollen and rubbing against itself’. Pfizer/BioNTech and Moderna vaccines use mRNA to change the cell while the Johnson & Johnson version uses DNA in a process similar to AstraZeneca’s technique. Johnson & Johnson and AstraZeneca have both had their ‘vaccines’ paused by many countries after causing serious blood problems. Terrell’s doctor Fnu Nutan said he could have died if he hadn’t got medical attention. It sounds terrible so what did Nutan and Terrell say about the ‘vaccine’ now? Oh, they still recommend that people have it. A nurse in a hospital bed 40 minutes after the vaccination and unable to swallow due to throat swelling was told by a doctor that he lost mobility in his arm for 36 hours following the vaccination. What did he say to the ailing nurse? ‘Good for you for getting the vaccination.’ We are dealing with a serious form of cognitive dissonance madness in both public and medical staff. There is a remarkable correlation between those having the ‘vaccine’ and trumpeting the fact and suffering bad happenings shortly afterwards. Witold Rogiewicz, a Polish doctor, made a video of his ‘vaccination’ and ridiculed those who were questioning its safety and the intentions of Bill Gates: ‘Vaccinate yourself to protect yourself, your loved ones, friends and also patients. And to mention quickly I have info for anti-vaxxers and anti-Coviders if you want to contact Bill Gates you can do this through me.’ He further ridiculed the dangers of 5G. Days later he was dead, but naturally the vaccination wasn't mentioned in the verdict of 'heart attack'.

Lies, lies and more lies

So many members of the human race have slipped into extreme states of insanity and unfortunately they include reframed doctors and nursing staff. Having a 'vaccine' and dying within minutes or hours is not considered a valid connection while death from any cause within 28 days or longer of a positive test with a test not testing for the 'virus' means 'Covid-19' goes on the death certificate. How could that 'vaccine'-death connection not have been made except by calculated deceit? US figures in the initial rollout period to February 12th, 2020, revealed that a third of the deaths reported to the CDC after 'Covid vaccines' happened within 48 hours. Five men in the UK suffered an 'extremely rare' blood clot problem after having the AstraZeneca 'vaccine', but no causal link was established said the Gates-funded Medicines and Healthcare products Regulatory Agency (MHRA) which had given the 'vaccine' emergency approval to be used. Former Pfizer executive Dr Michael Yeadon explained in his interview how the procedures could cause blood coagulation and clots. People who should have been at no risk were dying from blood clots in the brain and he said he had heard from medical doctor friends that people were suffering from skin bleeding and massive headaches. The AstraZeneca 'shot' was stopped by some 20 countries over the blood clotting issue and still the corrupt MHRA, the European Medicines Agency (EMA) and the World Health Organization said that it should continue to be given even though the EMA admitted that it 'still cannot rule out definitively' a link between blood clotting and the 'vaccine'. Later Marco Cavaleri, head of EMA vaccine strategy, said there was indeed a clear link between the 'vaccine' and thrombosis, but they didn't know why. So much for the trials showing the 'vaccine' is safe. Blood clots were affecting younger people who would be under virtually no danger from 'Covid' even if it existed which makes it all the more stupid and sinister.

The British government responded to public alarm by wheeling out June Raine, the terrifyingly weak infant school headmistress sound-alike who heads the UK MHRA drug 'regulator'. The idea that she would stand up to Big Pharma and government pressure is laughable and she told us that all was well in the same way that she did when allowing untested, never-used-on-humans-before, genetically-manipulating 'vaccines' to be exposed to the public in the first place. Mass lying is the new normal of the 'Covid' era. The MHRA later said 30 cases of rare blood clots had by then been connected with the AstraZeneca 'vaccine' (that means a lot more in reality) while stressing that the benefits of the jab in preventing 'Covid-19' outweighed any risks. A more ridiculous and disingenuous statement with callous disregard for human health it is hard to contemplate. Immediately after the mendacious 'all-clears' two hospital workers in Denmark experienced blood clots and cerebral haemorrhaging following the AstraZeneca jab and one died. Top Norwegian health official Pål Andre Holme said the 'vaccine' was the only common factor: 'There is nothing in the patient history of these individuals that can give such a powerful immune response … I am confident that the antibodies that we have found are the cause, and I see no other explanation than it being the vaccine which triggers it.' Strokes, a clot or bleed in the brain, were clearly associated with the 'vaccine' from word of mouth and whistleblower reports. Similar consequences followed with all these 'vaccines' that we were told were so safe and as the numbers grew by the day it was clear we were witnessing human carnage.

Learning the hard way

A woman interviewed by UKColumn told how her husband suffered dramatic health effects after the vaccine when he'd been in good health all his life. He went from being a little unwell to losing all feeling in his legs and experiencing 'excruciating pain'. Misdiagnosis followed twice at Accident and Emergency (an 'allergy' and 'sciatica') before he was admitted to a neurology ward where doctors said his serious condition had been caused by the 'vaccine'. Another seven 'vaccinated' people were apparently being treated on the same ward for similar symptoms. The woman said he had the 'vaccine' because they believed media claims that it was safe. 'I didn't think the government would give out a vaccine that does this to somebody; I believed they would be bringing out a vaccination that would be safe.' What a tragic way to learn that lesson. Another woman posted that her husband was transporting stroke patients to hospital on almost every shift and when he asked them if they had been 'vaccinated' for 'Covid' they all replied 'yes'. One had a 'massive brain bleed' the day after his second dose. She said her husband reported the 'just been vaccinated' information every time to doctors in A and E only for them to ignore it, make no notes and appear annoyed that it was even mentioned. This particular report cannot be verified, but it expresses a common theme that confirms the monumental underreporting of 'vaccine' consequences. Interestingly as the 'vaccines' and their brain blood clot/stroke consequences began to emerge the UK National Health Service began a publicity campaign telling the public what to do in the event of a stroke. A Scottish NHS staff nurse who quit in disgust in March, 2021, said:

> I have seen traumatic injuries from the vaccine, they're not getting reported to the yellow card [adverse reaction] scheme, they're treating the symptoms, not asking why, why it's happening. It's just treating the symptoms and when you speak about it you're dismissed like you're crazy, I'm not crazy, I'm not crazy because every other colleague I've spoken to is terrified to speak out, they've had enough.

Videos appeared on the Internet of people uncontrollably shaking after the 'vaccine' with no control over muscles, limbs and even their face. A Scottish mother broke out in a severe rash all over her body almost immediately after she was given the AstraZeneca 'vaccine'. The pictures were horrific. Leigh King, a 41-year-old hairdresser from Lanarkshire said: 'Never in my life was I prepared for what I was about to experience … My skin was so sore and constantly hot … I have never felt pain like this …' But don't you worry, the 'vaccine' is perfectly safe. Then there has been the effect on medical staff who have been pressured to have the 'vaccine' by psychopathic 'health' authorities and government. A London hospital consultant who gave the name K. Polyakova wrote this to the *British Medical Journal* or *BMJ*:

> I am currently struggling with … the failure to report the reality of the morbidity caused by our current vaccination program within the health service and staff population. The levels of sickness after vaccination is unprecedented and staff are getting very sick and some with neurological symptoms which is having a huge impact on the health service function. Even the young and healthy are off for days, some for weeks, and some requiring medical treatment. Whole teams are being taken out as they went to get vaccinated together.
>
> Mandatory vaccination in this instance is stupid, unethical and irresponsible when it comes to protecting our staff and public health. We are in the voluntary phase of vaccination, and encouraging staff to take an unlicensed product that is impacting on their immediate health … it is clearly stated that these vaccine products do not offer immunity or stop transmission. In which case why are we doing it?

Not to protect health that's for sure. Medical workers are lauded by governments for agenda reasons when they couldn't give a toss about them any more than they can for the population in general. Schools across America faced the same situation as they closed due to the high number of teachers and other staff with bad reactions to the Pfizer/BioNTech, Moderna, and Johnson & Johnson 'Covid vaccines' all of which were linked to death and serious adverse effects. The *BMJ* took down the consultant's comments pretty quickly on the grounds that they were being used to spread 'disinformation'. They were exposing the truth about the 'vaccine' was the real reason. The cover-up is breathtaking.

Hiding the evidence

The scale of the 'vaccine' death cover-up worldwide can be confirmed by comparing official figures with the personal experience of the public. I heard of many people in my community who died immediately or soon after the vaccine that would never appear in the media or even likely on the official totals of 'vaccine' fatalities and adverse reactions when only about ten percent are estimated to be reported and I have seen some estimates as low as one percent in a Harvard study. In the UK alone by April 29th, 2021, some 757,654 adverse reactions had been officially reported from the Pfizer/BioNTech, Oxford/AstraZeneca and Moderna 'vaccines' with more than a thousand deaths linked to jabs and that means an estimated ten times this number in reality from a ten percent reporting rate percentage. That's seven million adverse reactions and 10,000 potential deaths and a one percent reporting rate would be ten times *those* figures. In 1976 the US government pulled the swine flu vaccine after *53* deaths. The UK data included a combined 10,000 eye disorders from the 'Covid vaccines' with more than 750 suffering visual impairment or blindness and again multiply by the estimated reporting percentages. As 'Covid cases' officially fell hospitals virtually empty during the 'Covid crisis' began to fill up with a range of other problems in the wake of the 'vaccine' rollout. The numbers across America have also been catastrophic. Deaths linked to *all* types of vaccine increased by *6,000 percent* in the first quarter of 2021 compared with 2020. A 39-year-old woman from Ogden, Utah, died four days after receiving a second dose of Moderna's 'Covid vaccine' when her liver, heart and kidneys all failed despite the fact that she had no known medical issues or conditions. Her family sought an autopsy, but Dr Erik Christensen, Utah's chief medical examiner, said proving vaccine injury as a cause of death almost never happened. He could think of only one instance where an autopsy would name a vaccine as the official cause of death and that would be anaphylaxis where someone received a vaccine and died almost instantaneously. 'Short of that, it would be difficult for us to definitively say this is the vaccine,' Christensen said. If that is true this must be added to the estimated ten percent (or far less) reporting rate of vaccine deaths and serious reactions and the conclusion can only be that vaccine deaths and serious reactions – including these 'Covid' potions' – are phenomenally understated in official figures. The same story can be found everywhere. Endless accounts of deaths and serious reactions among the public, medical and care home staff while official figures did not even begin to reflect this.

Professional script-reader Dr David Williams, a 'top public-health official' in Ontario, Canada, insulted our intelligence by claiming only four serious adverse reactions and no deaths from the more than 380,000 vaccine doses then given. This bore no resemblance to what people knew had happened in their owns circles and we had Dirk Huyer in charge of getting millions vaccinated in Ontario while at the same time he was Chief Coroner for the province investigating causes of death including possible death from the vaccine. An aide said he had stepped back from investigating deaths, but evidence indicated otherwise. Rosemary Frei, who secured a Master of Science degree in molecular biology at the Faculty of Medicine at Canada's University of Calgary before turning to investigative journalism, was one who could see that official figures for 'vaccine' deaths and reactions made no sense. She said that doctors seldom reported adverse events and when people got really sick or died after getting a vaccination they would attribute that to anything except the vaccines. It had been that way for years and anyone who wondered aloud whether the 'Covid vaccines' or other shots cause harm is immediately branded as 'anti-vax' and 'anti-science'. This was 'career-threatening' for health professionals. Then there was the huge pressure to support the push to 'vaccinate' billions in the quickest time possible. Frei said:

> So that's where we're at today. More than half a million vaccine doses have been given to people in Ontario alone. The rush is on to vaccinate all 15 million of us in the province by September. And the mainstream media are screaming for this to be sped up even more. That all adds up to only a very slim likelihood that we're going to be told the truth by officials about how many people are getting sick or dying from the vaccines.

What is true of Ontario is true of everywhere.

They KNEW – and still did it

The authorities knew what was going to happen with multiple deaths and adverse reactions. The UK government's Gates-funded and Big Pharma-dominated Medicines and Healthcare products Regulatory Agency (MHRA) hired a company to employ AI in compiling the projected reactions to the 'vaccine' that would otherwise be uncountable. The request for applications said: 'The MHRA urgently seeks an Artificial Intelligence (AI) software tool to process the expected high volume of Covid-19 vaccine Adverse Drug Reaction …' This was from the agency, headed by the disingenuous June Raine, that gave the 'vaccines' emergency approval and the company was hired before the first shot was given. 'We are going to kill and maim you – is that okay?' 'Oh, yes, perfectly fine – I'm very grateful, thank you, doctor.' The range of 'Covid vaccine' adverse reactions goes on for page after page in the MHRA criminally underreported 'Yellow Card' system and includes affects to eyes, ears, skin, digestion, blood and so on. Raine's MHRA amazingly claimed that the 'overall safety experience … is so far as expected from the clinical trials'. The death, serious adverse effects, deafness and blindness were *expected?* When did they ever mention that? If these human tragedies were expected then those that gave approval for the use of these 'vaccines' must be guilty of crimes against humanity including murder – a definition of which is 'killing a person with malice aforethought or with recklessness manifesting extreme indifference to the value of human life.' People involved at the MHRA, the CDC in America and their equivalent around the world must go before Nuremberg trials to answer for their callous inhumanity. We are only talking here about the immediate effects of the 'vaccine'. The longer-term impact of the DNA synthetic manipulation is the main reason they are so hysterically desperate to inoculate the entire global population in the shortest possible time.

Africa and the developing world are a major focus for the 'vaccine' depopulation agenda and a mass vaccination sales-pitch is underway thanks to caring people like the Rockefellers and other Cult assets. The Rockefeller Foundation, which pre-empted the 'Covid pandemic' in a document published in 2010 that 'predicted' what happened a decade later, announced an initial $34.95 million grant in February, 2021, 'to ensure more equitable access to Covid-19 testing and vaccines' among other things in Africa in collaboration with '24 organizations, businesses, and government agencies'. The pan-Africa initiative would focus on 10 countries: Burkina Faso, Ethiopia, Ghana, Kenya, Nigeria, Rwanda, South Africa, Tanzania, Uganda, and Zambia'. Rajiv Shah, President of the Rockefeller Foundation and former administrator of CIA-controlled USAID, said that if Africa was not mass-vaccinated (to change the DNA of its people) it was a 'threat to all of humanity' and not fair on Africans. When someone from the Rockefeller Foundation says they want to do something to help poor and deprived people and countries it is time for a belly-laugh. They are doing this out of the goodness of their 'heart' because 'vaccinating' the entire global population is what the 'Covid' hoax set out to achieve. Official 'decolonisation' of Africa by the Cult was merely a prelude to financial colonisation on the road to a return to physical colonisation. The 'vaccine' is vital to that and the sudden and convenient death of the 'Covid' sceptic president of Tanzania can be seen in its true light. A lot of people in Africa are aware that this is another form of colonisation and exploitation and they need to stand their ground.

The 'vaccine is working' scam

A potential problem for the Cult was that the 'vaccine' is meant to change human DNA and body messaging and not to protect anyone from a 'virus' never shown to exist. The vaccine couldn't work because it was not designed to work and how could they make it *appear* to be working so that more people would have it? This was overcome by lowering the amplification rate of the PCR test to produce fewer 'cases' and therefore fewer 'deaths'. Some of us had been pointing out since March, 2020, that the amplification rate of the test not testing for the 'virus' had been made artificially high to generate positive tests which they could call 'cases' to justify lockdowns. The World Health Organization recommended an absurdly high 45 amplification cycles to ensure the high positives required by the Cult and then remained silent on the issue until January 20th, 2021 – Biden's Inauguration Day. This was when the 'vaccinations' were seriously underway and on that day the WHO recommended after discussions with America's CDC that laboratories *lowered their testing amplification*. Dr David Samadi, a certified urologist and health writer, said the WHO was encouraging all labs to reduce their cycle count for PCR tests. He said the current cycle was much too high and was 'resulting in any particle being declared a positive case'. Even one mainstream news report I saw said this meant the number of 'Covid' infections may have been 'dramatically inflated'. Oh, just a little bit. The CDC in America issued new guidance to laboratories in April, 2021, to use 28 cycles *but only for 'vaccinated' people*. The timing of the CDC/WHO interventions were cynically designed to make it appear the 'vaccines' were responsible for falling cases and deaths when the real reason can be seen in the following examples. New York's state lab, the Wadsworth Center, identified 872 positive tests in July, 2020, based on a threshold of 40 cycles. When the figure was lowered to 35 cycles *43 percent* of the 872 were no longer 'positives'. At 30 cycles the figure was 63 percent. A Massachusetts lab found that between *85 to 90 percent* of people who tested positive in July with a cycle threshold of 40 would be negative at 30 cycles, Ashish Jha, MD, director of the Harvard Global Health Institute, said: 'I'm really shocked that it could be that high … Boy, does it really change the way we need to be thinking about testing.' I'm shocked that I could see the obvious in the spring of 2020, with no medical background, and most medical professionals still haven't worked it out. No, that's not shocking – it's terrifying.

Three weeks after the WHO directive to lower PCR cycles the London *Daily Mail* ran this headline: 'Why ARE Covid cases plummeting? New infections have fallen 45% in the US and 30% globally in the past 3 weeks but experts say vaccine is NOT the main driver because only 8% of Americans and 13% of people worldwide have received their first dose.' They acknowledged that the drop could not be attributed to the 'vaccine', but soon this morphed throughout the media into the 'vaccine' has caused cases and deaths to fall when it was the PCR threshold. In December, 2020, there was chaos at English Channel ports with truck drivers needing negative ‘Covid’ tests before they could board a ferry home for Christmas. The government wanted to remove the backlog as fast as possible and they brought in troops to do the ‘testing’. Out of 1,600 drivers just *36* tested positive and the rest were given the all clear to cross the Channel. I guess the authorities thought that 36 was the least they could get away with without the unquestioning catching on. The amplification trick which most people believed in the absence of information in the mainstream applied more pressure on those refusing the ‘vaccine’ to succumb when it ‘obviously worked’. The truth was the exact opposite with deaths in care homes soaring with the ‘vaccine’ and in Israel the term used was ‘skyrocket’. A re-analysis of published data from the Israeli Health Ministry led by Dr Hervé Seligmann at the Medicine Emerging Infectious and Tropical Diseases at Aix-Marseille University found that Pfizer’s ‘Covid vaccine’ killed ‘about 40 times more [elderly] people than the disease itself would have killed’ during a five-week vaccination period and *260 times* more younger people than would have died from the ‘virus’ even according to the manipulated ‘virus’ figures. Dr Seligmann and his co-study author, Haim Yativ, declared after reviewing the Israeli ‘vaccine’ death data: ‘This is a new Holocaust.’

Then, in mid-April, 2021, after vast numbers of people worldwide had been ‘vaccinated’, the story changed with clear coordination. The UK government began to prepare the ground for more future lockdowns when Nuremberg-destined Boris Johnson told yet another whopper. He said that cases had fallen because of *lockdowns* not ‘vaccines’. Lockdowns are irrelevant when *there is no ‘virus’* and the test and fraudulent death certificates are deciding the number of ‘cases’ and ‘deaths’. Study after study has shown that lockdowns don’t work and instead kill and psychologically destroy people. Meanwhile in the United States Anthony Fauci and Rochelle Walensky, the ultra-Zionist head of the CDC, peddled the same line. More lockdown was the answer and not the ‘vaccine’, a line repeated on cue by the moron that is Canadian Prime Minister Justin Trudeau. Why all the hysteria to get everyone ‘vaccinated’ if lockdowns and not ‘vaccines’ made the difference? None of it makes sense on the face of it. Oh, but it does. The Cult wants lockdowns *and* the ‘vaccine’ and if the ‘vaccine’ is allowed to be seen as the total answer lockdowns would no longer be justified when there are still livelihoods to destroy. ‘Variants’ and renewed upward manipulation of PCR amplification are planned to instigate never-ending lockdown *and* more ‘vaccines’.

You *must* have it – we’re desperate

Israel, where the Jewish and Arab population are ruled by the Sabbatian Cult, was the front-runner in imposing the DNA-manipulating ‘vaccine’ on its people to such an extent that Jewish refusers began to liken what was happening to the early years of Nazi Germany. This would seem to be a fantastic claim. Why would a government of Jewish people be acting like the Nazis did? If you realise that the Sabbatian Cult was behind the Nazis and that Sabbatians hate Jews the pieces start to fit and the question of why a ‘Jewish’ government would treat Jews with such callous disregard for their lives and freedom finds an answer. Those controlling the government of Israel *aren’t Jewish* – they’re Sabbatian. Israeli lawyer Tamir Turgal was one who made the Nazi comparison in comments to German lawyer Reiner Fuellmich who is leading a class action lawsuit against the psychopaths for crimes against humanity. Turgal described how the Israeli government was vaccinating children and pregnant women on the basis that there was no evidence that this was dangerous when they had no evidence that it *wasn’t* dangerous either. They just had no evidence. This was medical experimentation and Turgal said this breached the Nuremberg Code about medical experimentation and procedures requiring informed consent and choice. Think about that. A Nuremberg Code developed because of Nazi experimentation on Jews and others in concentration camps by people like the evil-beyond-belief Josef Mengele is being breached by the *Israeli* government; but when you know that it’s a *Sabbatian* government along with its intelligence and military agencies like Mossad, Shin Bet and the Israeli Defense Forces, and that Sabbatians were the force behind the Nazis, the kaleidoscope comes into focus. What have we come to when Israeli Jews are suing their government for violating the Nuremberg Code by essentially making Israelis subject to a medical experiment using the controversial 'vaccines'? It's a shocker that this has to be done in the light of what happened in Nazi Germany. The Anshe Ha-Emet, or 'People of the Truth', made up of Israeli doctors, lawyers, campaigners and public, have launched a lawsuit with the International Criminal Court. It says:

> When the heads of the Ministry of Health as well as the prime minister presented the vaccine in Israel and began the vaccination of Israeli residents, the vaccinated were not advised, that, in practice, they are taking part in a medical experiment and that their consent is required for this under the Nuremberg Code.

The irony is unbelievable, but easily explained in one word: Sabbatians. The foundation of Israeli 'Covid' apartheid is the 'green pass' or 'green passport' which allows Jews and Arabs who have had the DNA-manipulating 'vaccine' to go about their lives – to work, fly, travel in general, go to shopping malls, bars, restaurants, hotels, concerts, gyms, swimming pools, theatres and sports venues, while non-'vaccinated' are banned from all those places and activities. Israelis have likened the 'green pass' to the yellow stars that Jews in Nazi Germany were forced to wear – the same as the yellow stickers that a branch of UK supermarket chain Morrisons told exempt mask-wears they had to display when shopping. How very sensitive. The Israeli system is blatant South African-style apartheid on the basis of compliance or non-compliance to fascism rather than colour of the skin. How appropriate that the Sabbatian Israeli government was so close to the pre-Mandela apartheid regime in Pretoria. The Sabbatian-instigated 'vaccine passport' in Israel is planned for everywhere. Sabbatians struck a deal with Pfizer that allowed them to lead the way in the percentage of a national population infused with synthetic material and the result was catastrophic. Israeli freedom activist Shai Dannon told me how chairs were appearing on beaches that said 'vaccinated only'. Health Minister Yuli Edelstein said that anyone unwilling or unable to get the jabs that 'confer immunity' will be 'left behind'. The man's a liar. Not even the makers claim the 'vaccines' confer immunity. When you see those figures of 'vaccine' deaths these psychopaths were saying that you must take the chance the 'vaccine' will kill you or maim you while knowing it will change your DNA or lockdown for you will be permanent. That's fascism. The Israeli parliament passed a law to allow personal information of the non-vaccinated to be shared with local and national authorities for three months. This was claimed by its supporters to be a way to 'encourage' people to be vaccinated. Hadas Ziv from Physicians for Human Rights described this as a 'draconian law which crushed medical ethics and the patient rights'. But that's the idea, the Sabbatians would reply.

Your papers, please

Sabbatian Israel was leading what has been planned all along to be a global 'vaccine pass' called a 'green passport' without which you would remain in permanent lockdown restriction and unable to do anything. This is how badly – *desperately* – the Cult is to get everyone 'vaccinated'. The term and colour 'green' was not by chance and related to the psychology of fusing the perception of the green climate hoax with the 'Covid' hoax and how the 'solution' to both is the same Great Reset. Lying politicians, health officials and psychologists denied there were any plans for mandatory vaccinations or restrictions based on vaccinations, but they knew that was exactly what was meant to happen with governments of all countries reaching agreements to enforce a global system. 'Free' Denmark and 'free' Sweden unveiled digital vaccine certification. Cyprus, Czech Republic, Estonia, Greece, Hungary, Iceland, Italy, Poland, Portugal, Slovakia, and Spain have all committed to a vaccine passport system and the rest including the whole of the EU would follow. The satanic UK government will certainly go this way despite mendacious denials and at the time of writing it is trying to manipulate the public into having the 'vaccine' so they could go abroad on a summer holiday. How would that work without something to prove you had the synthetic toxicity injected into you?

Documents show that the EU's European Commission was moving towards 'vaccine certificates' in 2018 and 2019 before the 'Covid' hoax began. They knew what was coming. Abracadabra – Ursula von der Leyen, the German President of the Commission, announced in March, 2021, an EU 'Digital Green Certificate' – green again – to track the public's 'Covid status'. The passport sting is worldwide and the Far East followed the same pattern with South Korea ruling that only those with 'vaccination' passports – again the *green* pass – would be able to 'return to their daily lives'.

Bill Gates has been preparing for this 'passport' with other Cult operatives for years and beyond the paper version is a Gates-funded 'digital tattoo' to identify who has been vaccinated and who hasn't. The 'tattoo' is reported to include a substance which is externally readable to confirm who has been vaccinated. This is a bio-luminous light-generating enzyme (think fireflies) called … *Luciferase*. Yes, named after the Cult 'god' Lucifer the 'light bringer' of whom more to come. Gates said he funded the readable tattoo to ensure children in the developing world were vaccinated and no one was missed out. He cares so much about poor kids as we know. This was just the cover story to develop a vaccine tagging system for everyone on the planet. Gates has been funding the ID2020 'alliance' to do just that in league with other lovely people at Microsoft, GAVI, the Rockefeller Foundation, Accenture and IDEO.org. He said in interviews in March, 2020, before any 'vaccine' publicly existed, that the world must have a globalised digital certificate to track the 'virus' and who had been vaccinated. Gates knew from the start that the mRNA vaccines were coming and when they would come and that the plan was to tag the 'vaccinated' to marginalise the intelligent and stop them doing anything including travel. Evil just doesn't suffice. Gates was exposed for offering a $10 million bribe to the Nigerian House of Representatives to invoke compulsory 'Covid' vaccination of all Nigerians. Sara Cunial, a member of the Italian Parliament, called Gates a 'vaccine criminal'. She urged the Italian President to hand him over to the International Criminal Court for crimes against humanity and condemned his plans to 'chip the human race' through ID2020.

You know it's a long-planned agenda when war criminal and Cult gofer Tony Blair is on the case. With the scale of arrogance only someone as dark as Blair can muster he said: 'Vaccination in the end is going to be your route to liberty.' Blair is a disgusting piece of work and he confirms that again. The media has given a lot of coverage to a bloke called Charlie Mullins, founder of London's biggest independent plumbing company, Pimlico Plumbers, who has said he won't employ anyone who has not been vaccinated or have them go to any home where people are not vaccinated. He said that if he had his way no one would be allowed to walk the streets if they have not been vaccinated. Gates was cheering at the time while I was alerting the white coats. The plan is that people will qualify for 'passports' for having the first two doses and then to keep it they will have to have all the follow ups and new ones for invented 'variants' until human genetics is transformed and many are dead who can't adjust to the changes. Hollywood celebrities – the usual propaganda stunt – are promoting something called the WELL Health-Safety Rating to verify that a building or space has 'taken the necessary steps to prioritize the health and safety of their staff, visitors and other stakeholders'. They included Lady Gaga, Jennifer Lopez, Michael B. Jordan, Robert DeNiro, Venus Williams, Wolfgang Puck, Deepak Chopra and 17th Surgeon General Richard Carmona. Yawn. WELL Health-Safety has big connections with China. Parent company Delos is headed by former Goldman Sachs partner Paul Scialla. This is another example – and we will see so many others – of using the excuse of 'health' to dictate the lives and activities of the population. I guess one confirmation of the 'safety' of buildings is that only 'vaccinated' people can go in, right?

Electronic concentration camps

I wrote decades ago about the plans to restrict travel and here we are for those who refuse to bow to tyranny. This can be achieved in one go with air travel if the aviation industry makes a blanket decree.

The ‘vaccine’ and guaranteed income are designed to be part of a global version of China’s social credit system which tracks behaviour 24/7 and awards or deletes ‘credits’ based on whether your behaviour is supported by the state or not. I mean your entire lifestyle – what you do, eat, say, everything. Once your credit score falls below a certain level consequences kick in. In China tens of millions have been denied travel by air and train because of this. All the locations and activities denied to refusers by the ‘vaccine’ passports will be included in one big mass ban on doing almost anything for those that don’t bow their head to government. It’s beyond fascist and a new term is required to describe its extremes – I guess fascist technocracy will have to do. The way the Chinese system of technological – technocratic – control is sweeping the West can be seen in the Los Angeles school system and is planned to be expanded worldwide. Every child is required to have a ‘Covid’-tracking app scanned daily before they can enter the classroom. The so-called Daily Pass tracking system is produced by Gates’ Microsoft which I’m sure will shock you rigid. The pass will be scanned using a barcode (one step from an inside-the-body barcode) and the information will include health checks, ‘Covid’ tests and vaccinations. Entry codes are for one specific building only and access will only be allowed if a student or teacher has a negative test with a test not testing for the ‘virus’, has no symptoms of anything alleged to be related to ‘Covid’ (symptoms from a range of other illness), and has a temperature under 100 degrees. No barcode, no entry, is planned to be the case for everywhere and not only schools.

Kids are being psychologically prepared to accept this as ‘normal’ their whole life which is why what they can impose in schools is so important to the Cult and its gofers. Long-time American freedom campaigner John Whitehead of the Rutherford Institute was not exaggerating when he said: ‘Databit by databit, we are building our own electronic concentration camps.’ Canada under its Cult gofer prime minister Justin Trudeau has taken a major step towards the real thing with people interned against their will if they test positive with a test not testing for the ‘virus’ when they arrive at a Canadian airport. They are jailed in internment hotels often without food or water for long periods and with many doors failing to lock there have been sexual assaults. The interned are being charged sometimes $2,000 for the privilege of being abused in this way. Trudeau is fully on board with the Cult and says the 'Covid pandemic' has provided an opportunity for a global 'reset' to permanently change Western civilisation. His number two, Deputy Prime Minister Chrystia Freeland, is a trustee of the World Economic Forum and a Rhodes Scholar. The Trudeau family have long been servants of the Cult. See *The Biggest Secret* and Cathy O'Brien's book *Trance-Formation of America* for the horrific background to Trudeau's father Pierre Trudeau another Canadian prime minister. Hide your fascism behind the façade of a heart-on-the-sleeve liberal. It's a well-honed Cult technique.

What can the 'vaccine' *really* do?

We have a 'virus' never shown to exist and 'variants' of the 'virus' that have also never been shown to exist except, like the 'original', as computer-generated fictions. Even if you believe there's a 'virus' the 'case' to 'death' rate is in the region of 0.23 to 0.15 percent and those 'deaths' are concentrated among the very old around the same average age that people die anyway. In response to this lack of threat (in truth none) psychopaths and idiots, knowingly and unknowingly answering to Gates and the Cult, are seeking to 'vaccinate' every man, woman and child on Planet Earth. Clearly the 'vaccine' is not about 'Covid' – none of this ever has been. So what is it all about *really*? Why the desperation to infuse genetically-manipulating synthetic material into everyone through mRNA fraudulent 'vaccines' with the intent of doing this over and over with the excuses of 'variants' and other 'virus' inventions? Dr Sherri Tenpenny, an osteopathic medical doctor in the United States, has made herself an expert on vaccines and their effects as a vehement campaigner against their use. Tenpenny was board certified in emergency medicine, the director of a level two trauma centre for 12 years, and moved to Cleveland in 1996 to start an integrative medicine practice which has treated patients from all 50 states and some 17 other countries. Weaning people off pharmaceutical drugs is a speciality.

She became interested in the consequences of vaccines after attending a meeting at the National Vaccine Information Center in Washington DC in 2000 where she 'sat through four days of listening to medical doctors and scientists and lawyers and parents of vaccine injured kids' and asked: 'What's going on?' She had never been vaccinated and never got ill while her father was given a list of vaccines to be in the military and was 'sick his entire life'. The experience added to her questions and she began to examine vaccine documents from the Centers for Disease Control (CDC). After reading the first one, the 1998 version of *The General Recommendations of Vaccination*, she thought: 'This is it?' The document was poorly written and bad science and Tenpenny began 20 years of research into vaccines that continues to this day. She began her research into 'Covid vaccines' in March, 2020, and she describes them as 'deadly'. For many, as we have seen, they already have been. Tenpenny said that in the first 30 days of the 'vaccine' rollout in the United States there had been more than 40,000 adverse events reported to the vaccine adverse event database. A document had been delivered to her the day before that was 172 pages long. 'We have over 40,000 adverse events; we have over 3,100 cases of [potentially deadly] anaphylactic shock; we have over 5,000 neurological reactions.' Effects ranged from headaches to numbness, dizziness and vertigo, to losing feeling in hands or feet and paraesthesia which is when limbs 'fall asleep' and people have the sensation of insects crawling underneath their skin. All this happened in the first 30 days and remember that only about *ten percent* (or far less) of adverse reactions and vaccine-related deaths are estimated to be officially reported. Tenpenny said:

> So can you think of one single product in any industry, any industry, for as long as products have been made on the planet that within 30 days we have 40,000 people complaining of side effects that not only is still on the market but … we've got paid actors telling us how great

> they are for getting their vaccine. We're offering people $500 if they will just get their vaccine and we've got nurses and doctors going; 'I got the vaccine, I got the vaccine'.

Tenpenny said they were not going to be 'happy dancing folks' when they began to suffer Bell's palsy (facial paralysis), neuropathies, cardiac arrhythmias and autoimmune reactions that kill through a blood disorder. 'They're not going to be so happy, happy then, but we're never going to see pictures of those people' she said. Tenpenny described the 'vaccine' as 'a well-designed killing tool'.

No off-switch

Bad as the initial consequences had been Tenpenny said it would be maybe 14 months before we began to see the 'full ravage' of what is going to happen to the 'Covid vaccinated' with full-out consequences taking anything between two years and 20 years to show. You can understand why when you consider that variations of the 'Covid vaccine' use mRNA (messenger RNA) to in theory activate the immune system to produce protective antibodies without using the actual 'virus'. How can they when it's a computer program and they've never isolated what they claim is the 'real thing'? Instead they use *synthetic* mRNA. They are inoculating synthetic material into the body which through a technique known as the Trojan horse is absorbed into cells to change the nature of DNA. Human DNA is changed by an infusion of messenger RNA and with each new 'vaccine' of this type it is changed even more. Say so and you are banned by Cult Internet platforms. The contempt the contemptuous Mark Zuckerberg has for the truth and human health can be seen in an internal Facebook video leaked to the Project Veritas investigative team in which he said of the 'Covid vaccines': '… I share some caution on this because we just don't know the long term side-effects of basically modifying people's DNA and RNA.' At the same time this disgusting man's Facebook was censoring and banning anyone saying exactly the same. He must go before a Nuremberg trial for crimes against humanity when he *knows* that he is censoring legitimate concerns and denying the right of informed consent on behalf of the Cult that owns him. People have been killed and damaged by the very 'vaccination' technique he cast doubt on himself when they may not have had the 'vaccine' with access to information that he denied them. The plan is to have at least annual 'Covid vaccinations', add others to deal with invented 'variants', and change all other vaccines into the mRNA system. Pfizer executives told shareholders at a virtual Barclays Global Healthcare Conference in March, 2021, that the public may need a third dose of 'Covid vaccine', plus regular yearly boosters and the company planned to hike prices to milk the profits in a 'significant opportunity for our vaccine'. These are the professional liars, cheats and opportunists who are telling you their 'vaccine' is safe. Given this volume of mRNA planned to be infused into the human body and its ability to then replicate we will have a transformation of human genetics from biological to synthetic biological – exactly the long-time Cult plan for reasons we'll see – and many will die. Sherri Tenpenny said of this replication:

> It's like having an on-button but no off-button and that whole mechanism … they actually give it a name and they call it the Trojan horse mechanism, because it allows that [synthetic] virus and that piece of that [synthetic] virus to get inside of your cells, start to replicate and even get inserted into other parts of your DNA as a Trojan-horse.

Ask the overwhelming majority of people who have the 'vaccine' what they know about the contents and what they do and they would reply: 'The government says it will stop me getting the virus.' Governments give that false impression on purpose to increase take-up. You can read Sherri Tenpenny's detailed analysis of the health consequences in her blog at Vaxxter.com, but in summary these are some of them. She highlights the statement by Bill Gates about how human beings can become their own 'vaccine manufacturing machine'. The man is insane. ['Vaccine'-generated] 'antibodies' carry synthetic messenger RNA into the cells and the damage starts, Tenpenny contends, and she says that lungs can be adversely affected through varying degrees of pus and bleeding which obviously affects breathing and would be dubbed ‘Covid-19’. Even more sinister was the impact of ‘antibodies’ on macrophages, a white blood cell of the immune system. They consist of Type 1 and Type 2 which have very different functions. She said Type 1 are ‘hyper-vigilant’ white blood cells which ‘gobble up’ bacteria etc. However, in doing so, this could cause inflammation and in extreme circumstances be fatal. She says these affects are mitigated by Type 2 macrophages which kick in to calm down the system and stop it going rogue. They clear up dead tissue debris and reduce inflammation that the Type 1 ‘fire crews’ have caused. Type 1 kills the infection and Type 2 heals the damage, she says. This is her punchline with regard to ‘Covid vaccinations’: She says that mRNA ‘antibodies’ block Type 2 macrophages by attaching to them and deactivating them. This meant that when the Type 1 response was triggered by infection there was nothing to stop that getting out of hand by calming everything down. There’s an on-switch, but no off-switch, she says. What follows can be ‘over and out, see you when I see you’.

Genetic suicide

Tenpenny also highlights the potential for autoimmune disease – the body attacking itself – which has been associated with vaccines since they first appeared. Infusing a synthetic foreign substance into cells could cause the immune system to react in a panic believing that the body is being overwhelmed by an invader (it is) and the consequences can again be fatal. There is an autoimmune response known as a ‘cytokine storm’ which I have likened to a homeowner panicked by an intruder and picking up a gun to shoot randomly in all directions before turning the fire on himself. The immune system unleashes a storm of inflammatory response called cytokines to a threat and the body commits hara-kiri. The lesson is that you mess with the body’s immune response at your peril and these ‘vaccines’ seriously – fundamentally – mess with immune response. Tenpenny refers to a consequence called anaphylactic shock which is a severe and highly dangerous allergic reaction when the immune system floods the body with chemicals. She gives the example of having a bee sting which primes the immune system and makes it sensitive to those chemicals. When people are stung again maybe years later the immune response can be so powerful that it leads to anaphylactic shock. Tenpenny relates this 'shock' with regard to the 'Covid vaccine' to something called polyethylene glycol or PEG. Enormous numbers of people have become sensitive to this over decades of use in a whole range of products and processes including food, drink, skin creams and 'medicine'. Studies have claimed that some 72 percent of people have antibodies triggered by PEG compared with two percent in the 1960s and allergic hypersensitive reactions to this become a gathering cause for concern. Tenpenny points out that the 'mRNA vaccine' is coated in a 'bubble' of polyethylene glycol which has the potential to cause anaphylactic shock through immune sensitivity. Many reports have appeared of people reacting this way after having the 'Covid vaccine'. What do we think is going to happen as humanity has more and more of these 'vaccines'? Tenpenny said: 'All these pictures we have seen with people with these rashes … these weepy rashes, big reactions on their arms and things like that – it's an acute allergic reaction most likely to the polyethylene glycol that you've been previously primed and sensitised to.'

Those who have not studied the conspiracy and its perpetrators at length might think that making the population sensitive to PEG and then putting it in these 'vaccines' is just a coincidence. It is not. It is instead testament to how carefully and coldly-planned current events have been and the scale of the conspiracy we are dealing with. Tenpenny further explains that the 'vaccine' mRNA procedure can breach the blood-brain barrier which protects the brain from toxins and other crap that will cause malfunction. In this case they could make two proteins corrupt brain function to cause Amyotrophic lateral sclerosis (ALS) , a progressive nervous system disease leading to loss of muscle control, and frontal lobe degeneration – Alzheimer's and dementia. Immunologist J. Bart Classon published a paper connecting mRNA 'vaccines' to prion disease which can lead to Alzheimer's and other forms of neurogenerative disease while others have pointed out the potential to affect the placenta in ways that make women infertile. This will become highly significant in the next chapter when I will discuss other aspects of this non-vaccine that relate to its nanotechnology and transmission from the injected to the uninjected.

Qualified in idiocy

Tenpenny describes how research has confirmed that these 'vaccine'-generated antibodies can interact with a range of other tissues in the body and attack many other organs including the lungs. 'This means that if you have a hundred people standing in front of you that all got this shot they could have a hundred different symptoms.' Anyone really think that Cult gofers like the Queen, Tony Blair, Christopher Whitty, Anthony Fauci, and all the other psychopaths have really had this 'vaccine' in the pictures we've seen? Not a bloody chance. Why don't doctors all tell us about all these dangers and consequences of the 'Covid vaccine'? Why instead do they encourage and pressure patients to have the shot? Don't let's think for a moment that doctors and medical staff can't be stupid, lazy, and psychopathic and that's without the financial incentives to give the jab. Tenpenny again:

> Some people are going to die from the vaccine directly but a large number of people are going to start to get horribly sick and get all kinds of autoimmune diseases 42 days to maybe a year out. What are they going to do, these stupid doctors who say; 'Good for you for getting that vaccine.' What are they going to say; 'Oh, it must be a mutant, we need to give an extra dose of that vaccine.'
>
> Because now the vaccine, instead of one dose or two doses we need three or four because the stupid physicians aren't taking the time to learn anything about it. If I can learn this sitting in my living room reading a 19 page paper and several others so can they. There's nothing special about me, I just take the time to do it.

Remember how Sara Kayat, the NHS and TV doctor, said that the 'Covid vaccine' would '100 percent prevent hospitalisation and death'. Doctors can be idiots like every other profession and they should not be worshipped as infallible. They are not and far from it. Behind many medical and scientific 'experts' lies an uninformed prat trying to hide themselves from you although in the 'Covid' era many have failed to do so as with UK narrative-repeating 'TV doctor' Hilary Jones. Pushing back against the minority of proper doctors and scientists speaking out against the 'vaccine' has been the entire edifice of the Cult global state in the form of governments, medical systems, corporations, mainstream media, Silicon Valley, and an army of compliant doctors, medical staff and scientists willing to say anything for money and to enhance their careers by promoting the party line. If you do that you are an 'expert' and if you won't you are an 'anti-vaxxer' and 'Covidiot'. The pressure to be 'vaccinated' is incessant. We have even had reports claiming that the 'vaccine' can help cure cancer and Alzheimer's and make the lame walk. I am waiting for the announcement that it can bring you coffee in the morning and cook your tea. Just as the symptoms of 'Covid' seem to increase by the week so have the miracles of the 'vaccine'. American supermarket giant Kroger Co. offered nearly 500,000 employees in 35 states a $100 bonus for having the 'vaccine' while donut chain Krispy Kreme promised 'vaccinated' customers a free glazed donut every day for the rest of 2021. Have your DNA changed and you will get a doughnut although we might not have to give you them for long. Such offers and incentives confirm the desperation.

Perhaps the worse vaccine-stunt of them all was UK 'Health' Secretary Matt-the-prat Hancock on live TV after watching a clip of someone being 'vaccinated' when the roll-out began. Hancock faked tears so badly it was embarrassing. Brain-of-Britain Piers Morgan, the lockdown-supporting, 'vaccine' supporting, 'vaccine' passport-supporting, TV host played along with Hancock – 'You're quite emotional about that' he said in response to acting so atrocious it would have been called out at a school nativity which will presumably today include Mary and Jesus in masks, wise men keeping their camels six feet apart, and shepherds under tent arrest. System-serving Morgan tweeted this: 'Love the idea of covid vaccine passports for everywhere: flights, restaurants, clubs, football, gyms, shops etc. It's time covid-denying, anti-vaxxer loonies had their bullsh*t bluff called & bar themselves from going anywhere that responsible citizens go.' If only I could aspire to his genius. To think that Morgan, who specialises in shouting over anyone he disagrees with, was lauded as a free speech hero when he lost his job after storming off the set of his live show like a child throwing his dolly out of the pram. If he is a free speech hero we are in real trouble. I have no idea what 'bullsh*t' means, by the way, the * throws me completely.

The Cult is desperate to infuse its synthetic DNA-changing concoction into everyone and has been using every lie, trick and intimidation to do so. The question of '*Why*?' we shall now address.

CHAPTER TEN

Human 2.0

I believe that at the end of the century the use of words and general educated opinion will have altered so much that one will be able to speak of machines thinking without expecting to be contradicted –
Alan Turing (1912-1954), the 'Father of artificial intelligence'

I have been exposing for decades the plan to transform the human body from a biological to a synthetic-biological state. The new human that I will call Human 2.0 is planned to be connected to artificial intelligence and a global AI 'Smart Grid' that would operate as one global system in which AI would control everything from your fridge to your heating system to your car to your mind. Humans would no longer be 'human', but post-human and sub-human, with their thinking and emotional processes replaced by AI.

What I said sounded crazy and beyond science fiction and I could understand that. To any balanced, rational, mind it *is* crazy. Today, however, that world is becoming reality and it puts the 'Covid vaccine' into its true context. Ray Kurzweil is the ultra-Zionist 'computer scientist, inventor and futurist' and co-founder of the Singularity University. Singularity refers to the merging of humans with machines or 'transhumanism'. Kurzweil has said humanity would be connected to the cyber 'cloud' in the period of the ever-recurring year of 2030:

> Our thinking … will be a hybrid of biological and non-biological thinking … humans will be able to extend their limitations and 'think in the cloud' … We're going to put gateways to the

> cloud in our brains … We're going to gradually merge and enhance ourselves … In my view, that's the nature of being human – we transcend our limitations. As the technology becomes vastly superior to what we are then the small proportion that is still human gets smaller and smaller and smaller until it's just utterly negligible.

They are trying to sell this end-of-humanity-as-we-know-it as the next stage of 'evolution' when we become super-human and 'like the gods'. They are lying to you. Shocked, eh? The population, and again especially the young, have been manipulated into addiction to technologies designed to enslave them for life. First they induced an addiction to smartphones (holdables); next they moved to technology on the body (wearables); and then began the invasion of the body (implantables). I warned way back about the plan for microchipped people and we are now entering that era. We should not be diverted into thinking that this refers only to chips we can see. Most important are the nanochips known as smart dust, neural dust and nanobots which are far too small to be seen by the human eye. Nanotechnology is everywhere, increasingly in food products, and released into the atmosphere by the geoengineering of the skies funded by Bill Gates to 'shut out the Sun' and 'save the planet from global warming'. Gates has been funding a project to spray millions of tonnes of chalk (calcium carbonate) into the stratosphere over Sweden to 'dim the Sun' and cool the Earth. Scientists warned the move could be disastrous for weather systems in ways no one can predict and opposition led to the Swedish space agency announcing that the 'experiment' would not be happening as planned in the summer of 2021; but it shows where the Cult is going with dimming the impact of the Sun and there's an associated plan to change the planet's atmosphere. Who gives psychopath Gates the right to dictate to the entire human race and dismantle planetary systems? The world will not be safe while this man is at large.

The global warming hoax has made the Sun, like the gas of life, something to fear when both are essential to good health and human survival (more inversion). The body transforms sunlight into vital vitamin D through a process involving … *cholesterol*. This is the cholesterol we are also told to fear. We are urged to take Big Pharma statin drugs to reduce cholesterol and it's all systematic. Reducing cholesterol means reducing vitamin D uptake with all the multiple health problems that will cause. At least if you take statins long term it saves the government from having to pay you a pension. The delivery system to block sunlight is widely referred to as chemtrails although these have a much deeper agenda, too. They appear at first to be contrails or condensation trails streaming from aircraft into cold air at high altitudes. Contrails disperse very quickly while chemtrails do not and spread out across the sky before eventually their content falls to earth. Many times I have watched aircraft cross-cross a clear blue sky releasing chemtrails until it looks like a cloudy day. Chemtrails contain many things harmful to humans and the natural world including toxic heavy metals, aluminium (see Alzheimer's) and nanotechnology. Ray Kurzweil reveals the reason without actually saying so: 'Nanobots will infuse all the matter around us with information. Rocks, trees, everything will become these intelligent creatures.' How do you deliver that? *From the sky*. Self-replicating nanobots would connect everything to the Smart Grid. The phenomenon of Morgellons disease began in the chemtrail era and the correlation has led to it being dubbed the 'chemtrail disease'. Self-replicating fibres appear in the body that can be pulled out through the skin. Morgellons fibres continue to grow outside the body and have a form of artificial intelligence. I cover this at greater length in *Phantom Self*.

'Vaccine' operating system

'Covid vaccines' with their self-replicating synthetic material are also designed to make the connection between humanity and Kurzweil's 'cloud'. American doctor and dedicated campaigner for truth, Carrie Madej, an Internal Medicine Specialist in Georgia with more than 20 years medical experience, has highlighted the nanotechnology aspect of the fake 'vaccines'. She explains how one of the components in at least the Moderna and Pfizer synthetic potions are 'lipid nanoparticles' which are 'like little tiny computer bits' – a 'sci-fi substance' known as nanobots and hydrogel which can be 'triggered at any moment to deliver its payload' and act as 'biosensors'. The synthetic substance had 'the ability to accumulate data from your body like your breathing, your respiration, thoughts and emotions, all kind of things' and each syringe could carry a *million* nanobots:

> This substance because it's like little bits of computers in your body, crazy, but it's true, it can do that, [and] obviously has the ability to act through Wi-Fi. It can receive and transmit energy, messages, frequencies or impulses. That issue has never been addressed by these companies. What does that do to the human?
>
> Just imagine getting this substance in you and it can react to things all around you, the 5G, your smart device, your phones, what is happening with that? What if something is triggering it, too, like an impulse, a frequency? We have something completely foreign in the human body.

Madej said her research revealed that electromagnetic (EMF) frequencies emitted by phones and other devices had increased dramatically in the same period of the 'vaccine' rollout and she was seeing more people with radiation problems as 5G and other electromagnetic technology was expanded and introduced to schools and hospitals. She said she was 'floored with the EMF coming off' the devices she checked. All this makes total sense and syncs with my own work of decades when you think that Moderna refers in documents to its mRNA 'vaccine' as an 'operating system':

> Recognizing the broad potential of mRNA science, we set out to create an mRNA technology platform that functions very much like an operating system on a computer. It is designed so that it can plug and play interchangeably with different programs. In our case, the 'program' or 'app' is our mRNA drug – the unique mRNA sequence that codes for a protein …
>
> … Our MRNA Medicines – 'The 'Software Of Life': When we have a concept for a new mRNA medicine and begin research, fundamental components are already in place. Generally, the only thing that changes from one potential mRNA medicine to another is the coding region – the actual genetic code that instructs ribosomes to make protein. Utilizing these instruction sets gives our investigational mRNA medicines a software-like quality. We also have the ability to combine different mRNA sequences encoding for different proteins in a single mRNA investigational medicine.

Who needs a real 'virus' when you can create a computer version to justify infusing your operating system into the entire human race on the road to making living, breathing people into cyborgs? What is missed with the 'vaccines' is the *digital* connection between synthetic material and the body that I highlighted earlier with the study that hacked a computer with human DNA. On one level the body is digital, based on mathematical codes, and I'll have more about that in the next chapter. Those who ridiculously claim that mRNA 'vaccines' are not designed to change human genetics should explain the words of Dr Tal Zaks, chief medical officer at Moderna, in a 2017 TED talk. He said that over the last 30 years 'we've been living this phenomenal digital scientific revolution, and I'm here today to tell you, that we are actually *hacking the software of life*, and that it's changing the way we think about prevention and treatment of disease':

> In every cell there's this thing called messenger RNA, or mRNA for short, that transmits the critical information from the DNA in our genes to the protein, which is really the stuff we're all made out of. This is the critical information that determines what the cell will do. So we think about it as an operating system. So if you could change that, if you could introduce a line of code, or change a line of code, it turns out, that has profound implications for everything, from the flu to cancer.

Zaks should more accurately have said that this has profound implications for the human genetic code and the nature of DNA. Communications within the body go both ways and not only one. But, hey, no, the 'Covid vaccine' will not affect your genetics. Cult fact-checkers say so even though the man who helped to develop the mRNA technique says that it does. Zaks said in 2017:

> If you think about what it is we're trying to do. We've taken information and our understanding of that information and how that information is transmitted in a cell, and we've taken our understanding of medicine and how to make drugs, and we're fusing the two. We think of it as information therapy.

I have been writing for decades that the body is an information field communicating with itself and the wider world. This is why radiation which is information can change the information field of body and mind through phenomena like 5G and change their nature and function. ‘Information therapy’ means to change the body’s information field and change the way it operates. DNA is a receiver-transmitter of information and can be mutated by information like mRNA synthetic messaging. Technology to do this has been ready and waiting in the underground bases and other secret projects to be rolled out when the ‘Covid’ hoax was played. ‘Trials’ of such short and irrelevant duration were only for public consumption. When they say the ‘vaccine’ is ‘experimental’ that is not true. It may appear to be ‘experimental’ to those who don’t know what’s going on, but the trials have already been done to ensure the Cult gets the result it desires. Zaks said that it took decades to sequence the human genome, completed in 2003, but now they could do it in a week. By ‘they’ he means scientists operating in the public domain. In the secret projects they were sequencing the genome in a week long before even 2003.

Deluge of mRNA

Highly significantly the Moderna document says the guiding premise is that if using mRNA as a medicine works for one disease then it should work for many diseases. They were leveraging the flexibility afforded by their platform and the fundamental role mRNA plays in protein synthesis to pursue mRNA medicines for a broad spectrum of diseases. Moderna is confirming what I was saying through 2020 that multiple ‘vaccines’ were planned for ‘Covid’ (and later invented ‘variants’) and that previous vaccines would be converted to the mRNA system to infuse the body with massive amounts of genetically-manipulating synthetic material to secure a transformation to a synthetic-biological state. The ‘vaccines’ are designed to kill stunning numbers as part of the long-exposed Cult depopulation agenda and transform the rest. Given this is the goal you can appreciate why there is such hysterical demand for every human to be ‘vaccinated’ for an alleged ‘disease’ that has an estimated ‘infection’ to ‘death’ ratio of 0.23-0.15 percent. As I write children are being given the ‘vaccine’ in trials (their parents are a disgrace) and ever-younger people are being offered the vaccine for a ‘virus’ that even if you believe it exists has virtually zero chance of harming them. Horrific effects of the ‘trials’ on a 12-year-old girl were revealed by a family member to be serious brain and gastric problems that included a bowel obstruction and the inability to swallow liquids or solids. She was unable to eat or drink without throwing up, had extreme pain in her back, neck and abdomen, and was paralysed from the waist down which stopped her urinating unaided. When the girl was first taken to hospital doctors said it was all in her mind. She was signed up for the ‘trial’ by her parents for whom no words suffice. None of this ‘Covid vaccine’ insanity makes any sense unless you see what the ‘vaccine’ really is – a body-changer. Synthetic biology or ‘SynBio’ is a fast-emerging and expanding scientific discipline which includes everything from genetic and molecular engineering to electrical and computer engineering. Synthetic biology is defined in these ways:

- A multidisciplinary area of research that seeks to create new biological parts, devices, and systems, or to redesign systems that are already found in nature.
- The use of a mixture of physical engineering and genetic engineering to create new (and therefore synthetic) life forms.
- An emerging field of research that aims to combine the knowledge and methods of biology, engineering and related disciplines in the design of chemically-synthesized DNA to create organisms with novel or enhanced characteristics and traits (synthetic organisms including humans).

We now have synthetic blood, skin, organs and limbs being developed along with synthetic body parts produced by 3D printers. These are all elements of the synthetic human programme and this comment by Kurzweil’s co-founder of the Singularity University, Peter Diamandis, can be seen in a whole new light with the 'Covid' hoax and the sanctions against those that refuse the 'vaccine':

> Anybody who is going to be resisting the progress forward [to transhumanism] is going to be resisting evolution and, fundamentally, they will die out. It's not a matter of whether it's good or bad. It's going to happen.

'Resisting evolution'? What absolute bollocks. The arrogance of these people is without limit. His 'it's going to happen' mantra is another way of saying 'resistance is futile' to break the spirit of those pushing back and we must not fall for it. Getting this genetically-transforming 'vaccine' into everyone is crucial to the Cult plan for total control and the desperation to achieve that is clear for anyone to see. Vaccine passports are a major factor in this and they, too, are a form of resistance is futile. It's NOT. The paper funded by the Rockefeller Foundation for the 2013 'health conference' in China said:

> We will interact more with artificial intelligence. The use of robotics, bio-engineering to augment human functioning is already well underway and will advance. Re-engineering of humans into potentially separate and unequal forms through genetic engineering or mixed human-robots raises debates on ethics and equality.
>
> A new demography is projected to emerge after 2030 [that year again] of technologies (robotics, genetic engineering, nanotechnology) producing robots, engineered organisms, 'nanobots' and artificial intelligence (AI) that can self-replicate. Debates will grow on the implications of an impending reality of human designed life.

What is happening today is so long planned. The world army enforcing the will of the world government is intended to be a robot army, not a human one. Today's military and its technologically 'enhanced' troops, pilotless planes and driverless vehicles are just stepping stones to that end. Human soldiers are used as Cult fodder and its time they woke up to that and worked for the freedom of the population instead of their own destruction and their family's destruction – the same with the police. Join us and let's sort this out. The phenomenon of enforce my own destruction is widespread in the 'Covid' era with Woker 'luvvies' in the acting and entertainment industries supporting ‘Covid’ rules which have destroyed their profession and the same with those among the public who put signs on the doors of their businesses ‘closed due to Covid – stay safe’ when many will never reopen. It’s a form of masochism and most certainly insanity.

Transgender = transhumanism

When something explodes out of nowhere and is suddenly everywhere it is always the Cult agenda and so it is with the tidal wave of claims and demands that have infiltrated every aspect of society under the heading of ‘transgenderism’. The term ‘trans’ is so ‘in’ and this is the dictionary definition:

> A prefix meaning ‘across’, ’through’, occurring … in loanwords from Latin, used in particular for denoting movement or conveyance from place to place (transfer; transmit; transplant) or complete change (transform; transmute), or to form adjectives meaning ’crossing’, ‘on the other side of’, or ‘going beyond’ the place named (transmontane; transnational; trans-Siberian).

Transgender means to go beyond gender and transhuman means to go beyond human. Both are aspects of the Cult plan to transform the human body to a synthetic state with *no gender*. Human 2.0 is not designed to procreate and would be produced technologically with no need for parents. The new human would mean the end of parents and so men, and increasingly women, are being targeted for the deletion of their rights and status. Parental rights are disappearing at an ever-quickening speed for the same reason. The new human would have no need for men or women when there is no procreation and no gender. Perhaps the transgender movement that appears to be in a permanent state of frenzy might now contemplate on how it is being used. This was never about transgender rights which are only the interim excuse for confusing gender, particularly in the young, on the road to *fusing* gender. Transgender activism is not an end; it is a *means* to an end. We see again the technique of creative destruction in which you destroy the status quo to ‘build back better’ in the form that you want. The gender status quo had to be destroyed by persuading the Cult-created Woke mentality to believe that you can have 100 genders or more. A programme for 9 to 12 year olds produced by the Cult-owned BBC promoted the 100 genders narrative. The very idea may be the most monumental nonsense, but it is not what is true that counts, only what you can make people *believe* is true. Once the gender of 2 + 2 = 4 has been dismantled through indoctrination, intimidation and 2 + 2 = 5 then the new no-gender normal can take its place with Human 2.0. Aldous Huxley revealed the plan in his prophetic *Brave New World* in 1932:

> Natural reproduction has been done away with and children are created, decanted', and raised in 'hatcheries and conditioning centres'. From birth, people are genetically designed to fit into one of five castes, which are further split into 'Plus' and 'Minus' members and designed to fulfil predetermined positions within the social and economic strata of the World State.

How could Huxley know this in 1932? For the same reason George Orwell knew about the Big Brother state in 1948, Cult insiders I have quoted knew about it in 1969, and I have known about it since the early 1990s. If you are connected to the Cult or you work your balls off to uncover the plan you can predict the future. The process is simple. If there is a plan for the world and nothing intervenes to stop it then it will happen. Thus if you communicate the plan ahead of time you are perceived to have predicted the future, but you haven't. You have revealed the plan which without intervention will become the human future. The whole reason I have done what I have is to alert enough people to inspire an intervention and maybe at last that time has come with the Cult and its intentions now so obvious to anyone with a brain in working order.

The future is here

Technological wombs that Huxley described to replace parent procreation are already being developed and they are only the projects we know about in the public arena. Israeli scientists told *The Times of Israel* in March, 2021, that they have grown 250-cell embryos into mouse foetuses with fully formed organs using artificial wombs in a development they say could pave the way for gestating humans outside the womb. Professor Jacob Hanna of the Weizmann Institute of Science said:

> We took mouse embryos from the mother at day five of development, when they are just of 250 cells, and had them in the incubator from day five until day 11, by which point they had grown all their organs.
>
> By day 11 they make their own blood and have a beating heart, a fully developed brain. Anybody would look at them and say, 'this is clearly a mouse foetus with all the characteristics of a mouse.' It's gone from being a ball of cells to being an advanced foetus.

A special liquid is used to nourish embryo cells in a laboratory dish and they float on the liquid to duplicate the first stage of embryonic development. The incubator creates all the right conditions for its development, Hanna said. The liquid gives the embryo 'all the nutrients, hormones and sugars they need' along with a custom-made electronic incubator which controls gas concentration, pressure and temperature. The cutting-edge in the underground bases and other secret locations will be light years ahead of that, however, and this was reported by the London *Guardian* in 2017:

> We are approaching a biotechnological breakthrough. Ectogenesis, the invention of a complete external womb, could completely change the nature of human reproduction. In April this year, researchers at the Children's Hospital of Philadelphia announced their development of an artificial womb.

The article was headed 'Artificial wombs could soon be a reality. What will this mean for women?' What would it mean for children is an even bigger question. No mother to bond with only a machine in preparation for a life of soulless interaction and control in a world governed by machines (see the *Matrix* movies). Now observe the calculated manipulations of the 'Covid' hoax as human interaction and warmth has been curtailed by distancing, isolation and fear with people communicating via machines on a scale never seen before.

These are all dots in the same picture as are all the personal assistants, gadgets and children's toys through which kids and adults communicate with AI as if it is human. The AI 'voice' on Sat-Nav should be included. All these things are psychological preparation for the Cult endgame. Before you can make a physical connection with AI you have to make a psychological connection and that is what people are being conditioned to do with this ever gathering human-AI interaction. Movies and TV programmes depicting the transhuman, robot dystopia relate to a phenomenon known as 'pre-emptive programming' in which the world that is planned is portrayed everywhere in movies, TV and advertising. This is conditioning the conscious and subconscious mind to become familiar with the planned reality to dilute resistance when it happens for real. What would have been a shock such is the change is made less so. We have young children put on the road to transgender transition surgery with puberty blocking drugs at an age when they could never be able to make those life-changing decisions.

Rachel Levine, a professor of paediatrics and psychiatry who believes in treating children this way, became America's highest-ranked openly-transgender official when she was confirmed as US Assistant Secretary at the Department of Health and Human Services after being nominated by Joe Biden (the Cult). Activists and governments press for laws to deny parents a say in their children's transition process so the kids can be isolated and manipulated into agreeing to irreversible medical procedures. A Canadian father Robert Hoogland was denied bail by the Vancouver Supreme Court in 2021 and remained in jail for breaching a court order that he stay silent over his young teenage daughter, a minor, who was being offered life-changing hormone therapy without parental consent. At the age of 12 the girl's 'school counsellor' said she may be transgender, referred her to a doctor and told the school to treat her like a boy. This is another example of state-serving schools imposing ever more control over children's lives while parents have ever less.

Contemptible and extreme child abuse is happening all over the world as the Cult gender-fusion operation goes into warp-speed.

Why the war on men – and now women?

The question about what artificial wombs mean for women should rightly be asked. The answer can be seen in the deletion of women's rights involving sport, changing rooms, toilets and status in favour of people in male bodies claiming to identify as women. I can identify as a mountain climber, but it doesn't mean I can climb a mountain any more than a biological man can be a biological woman. To believe so is a triumph of belief over factual reality which is the very perceptual basis of everything Woke. Women's sport is being destroyed by allowing those with male bodies who say they identify as female to 'compete' with girls and women. Male body 'women' dominate 'women's' competition with their greater muscle mass, bone density, strength and speed. With that disadvantage sport for women loses all meaning. To put this in perspective nearly 300 American high school boys can run faster than the quickest woman sprinter in the world. Women are seeing their previously protected spaces invaded by male bodies simply because they claim to identify as women. That's all they need to do to access all women's spaces and activities under the Biden 'Equality Act' that destroys equality for women with the usual Orwellian Woke inversion. Male sex offenders have already committed rapes in women's prisons after claiming to identify as women to get them transferred. Does this not matter to the Woke 'equality' hypocrites? Not in the least. What matters to Cult manipulators and funders behind transgender activists is to advance gender fusion on the way to the no-gender 'human'. When you are seeking to impose transparent nonsense like this, or the 'Covid' hoax, the only way the nonsense can prevail is through censorship and intimidation of dissenters, deletion of factual information, and programming of the unquestioning, bewildered and naive. You don't have to scan the world for long to see that all these things are happening.

Many women's rights organisations have realised that rights and status which took such a long time to secure are being eroded and that it is systematic. Kara Dansky of the global Women's Human Rights Campaign said that Biden's transgender executive order immediately he took office, subsequent orders, and Equality Act legislation that followed 'seek to erase women and girls in the law as a category'. *Exactly*. I said during the long ago-started war on men (in which many women play a crucial part) that this was going to turn into a war on them. The Cult is phasing out *both* male and female genders. To get away with that they are brought into conflict so they are busy fighting each other while the Cult completes the job with no unity of response. Unity, people, *unity*. We need unity everywhere. Transgender is the only show in town as the big step towards the no-gender human. It's not about rights for transgender people and never has been. Woke political correctness is deleting words relating to genders to the same end. Wokers believe this is to be 'inclusive' when the opposite is true. They are deleting words describing gender because gender *itself* is being deleted by Human 2.0. Terms like 'man', 'woman', 'mother' and 'father' are being deleted in the universities and other institutions to be replaced by the *no*-gender, not trans-gender, 'individuals' and 'guardians'. Women's rights campaigner Maria Keffler of Partners for Ethical Care said: 'Children are being taught from kindergarten upward that some boys have a vagina, some girls have a penis, and that kids can be any gender they want to be.' Do we really believe that suddenly countries all over the world at the same time had the idea of having drag queens go into schools or read transgender stories to very young children in the local library? It's coldly-calculated confusion of gender on the way to the fusion of gender. Suzanne Vierling, a psychologist from Southern California, made another important point:

> Yesterday's slave woman who endured gynecological medical experiments is today's girl-child being butchered in a booming gender-transitioning sector. Ovaries removed, pushing her into menopause and osteoporosis, uncharted territory, and parents' rights and authority decimated.

The erosion of parental rights is a common theme in line with the Cult plans to erase the very concept of parents and 'ovaries removed, pushing her into menopause' means what? Those born female lose the ability to have children – another way to discontinue humanity as we know it.

Eliminating Human 1.0 (before our very eyes)

To pave the way for Human 2.0 you must phase out Human 1.0. This is happening through plummeting sperm counts and making women infertile through an onslaught of chemicals, radiation (including smartphones in pockets of men) and mRNA 'vaccines'. Common agriculture pesticides are also having a devastating impact on human fertility. I have been tracking collapsing sperm counts in the books for a long time and in 2021 came a book by fertility scientist and reproductive epidemiologist Shanna Swan, *Count Down: How Our Modern World Is Threatening Sperm Counts, Altering Male and Female Reproductive Development and Imperiling the Future of the Human Race*. She reports how the global fertility rate dropped by *half* between 1960 and 2016 with America's birth rate 16 percent below where it needs to be to sustain the population. Women are experiencing declining egg quality, more miscarriages, and more couples suffer from infertility. Other findings were an increase in erectile dysfunction, infant boys developing more genital abnormalities, male problems with conception, and plunging levels of the male hormone testosterone which would explain why so many men have lost their backbone and masculinity. This has been very evident during the 'Covid' hoax when women have been prominent among the Pushbackers and big strapping blokes have bowed their heads, covered their faces with a nappy and quietly submitted. Mind control expert Cathy O'Brien also points to how global education introduced the concept of 'we're all winners' in sport and classrooms: 'Competition was defused, and it in turn defused a sense of fighting back.' This is another version of the 'equity' doctrine in which you drive down rather than raise up. What a contrast in Cult-controlled China with its global ambitions where the government published plans in January, 2021, to ‘cultivate masculinity’ in boys from kindergarten through to high school in the face of a ‘masculinity crisis’. A government adviser said boys would be soon become ‘delicate, timid and effeminate’ unless action was taken. Don’t expect any similar policy in the targeted West. A 2006 study showed that a 65-year-old man in 2002 had testosterone levels *15 percent* lower than a 65-year-old man in 1987 while a 2020 study found a similar story with young adults and adolescents. Men are getting prescriptions for testosterone replacement therapy which causes an even greater drop in sperm count with up to 99 percent seeing sperm counts drop to zero during the treatment. More sperm is defective and malfunctioning with some having two heads or not pursuing an egg.

A class of *synthetic* chemicals known as phthalates are being blamed for the decline. These are found everywhere in plastics, shampoos, cosmetics, furniture, flame retardants, personal care products, pesticides, canned foods and even receipts. Why till receipts? Everyone touches them. Let no one delude themselves that all this is not systematic to advance the long-time agenda for human body transformation. Phthalates mimic hormones and disrupt the hormone balance causing testosterone to fall and genital birth defects in male infants. Animals and fish have been affected in the same way due to phthalates and other toxins in rivers. When fish turn gay or change sex through chemicals in rivers and streams it is a pointer to why there has been such an increase in gay people and the sexually confused. It doesn’t matter to me what sexuality people choose to be, but if it’s being affected by chemical pollution and consumption then we need to know. Does anyone really think that this is not connected to the transgender agenda, the war on men and the condemnation of male ‘toxic masculinity’? You watch this being followed by ‘toxic femininity’. It’s already happening. When breastfeeding becomes ‘chest-feeding’, pregnant women become pregnant people along with all the other Woke claptrap you know that the world is going insane and there’s a Cult scam in progress. Transgender activists are promoting the Cult agenda while Cult billionaires support and fund the insanity as they laugh themselves to sleep at the sheer stupidity for which humans must be infamous in galaxies far, far away.

‘Covid vaccines’ and female infertility

We can now see why the ‘vaccine’ has been connected to potential infertility in women. Dr Michael Yeadon, former Vice President and Chief Scientific Advisor at Pfizer, and Dr Wolfgang Wodarg in Germany, filed a petition with the European Medicines Agency in December, 2020, urging them to stop trials for the Pfizer/BioNTech shot and all other mRNA trials until further studies had been done. They were particularly concerned about possible effects on fertility with ‘vaccine’-produced antibodies attacking the protein Syncytin-1 which is responsible for developing the placenta. The result would be infertility ‘of indefinite duration’ in women who have the ‘vaccine’ with the placenta failing to form. Section 10.4.2 of the Pfizer/BioNTech trial protocol says that pregnant women or those who might become so should not have mRNA shots. Section 10.4 warns men taking mRNA shots to ‘be abstinent from heterosexual intercourse’ and not to donate sperm. The UK government said that it *did not know* if the mRNA procedure had an effect on fertility. *Did not know?* These people have to go to jail. UK government advice did not recommend at the start that pregnant women had the shot and said they should avoid pregnancy for at least two months after ‘vaccination’. The ‘advice’ was later updated to pregnant women should only have the ‘vaccine’ if the benefits outweighed the risks to mother and foetus. What the hell is that supposed to mean? Then ‘spontaneous abortions’ began to appear and rapidly increase on the adverse reaction reporting schemes which include only a fraction of adverse reactions. Thousands and ever-growing numbers of ‘vaccinated’ women are describing changes to their menstrual cycle with heavier blood flow, irregular periods and menstruating again after going through the menopause – all links to reproduction effects. Women are passing blood clots and the lining of their uterus while men report erectile dysfunction and blood effects. Most significantly of all *un*vaccinated women began to report similar menstrual changes after interaction with *'vaccinated'* people and men and children were also affected with bleeding noses, blood clots and other conditions. 'Shedding' is when vaccinated people can emit the content of a vaccine to affect the unvaccinated, but this is different. 'Vaccinated' people were not shedding a 'live virus' allegedly in 'vaccines' as before because the fake 'Covid vaccines' involve synthetic material and other toxicity. Doctors exposing what is happening prefer the term 'transmission' to shedding. Somehow those that have had the shots are transmitting effects to those that haven't. Dr Carrie Madej said the nano-content of the 'vaccines' can 'act like an antenna' to others around them which fits perfectly with my own conclusions. This 'vaccine' transmission phenomenon was becoming known as the book went into production and I deal with this further in the Postscript.

Vaccine effects on sterility are well known. The World Health Organization was accused in 2014 of sterilising millions of women in Kenya with the evidence confirmed by the content of the vaccines involved. The same WHO behind the 'Covid' hoax admitted its involvement for more than ten years with the vaccine programme. Other countries made similar claims. Charges were lodged by Tanzania, Nicaragua, Mexico, and the Philippines. The Gardasil vaccine claimed to protect against a genital 'virus' known as HPV has also been linked to infertility. Big Pharma and the WHO (same thing) are criminal and satanic entities. Then there's the Bill Gates Foundation which is connected through funding and shared interests with 20 pharmaceutical giants and laboratories. He stands accused of directing the policy of United Nations Children's Fund (UNICEF), vaccine alliance GAVI, and other groupings, to advance the vaccine agenda and silence opposition at great cost to women and children. At the same time Gates wants to reduce the global population. Coincidence?

Great Reset = Smart Grid = new human

The Cult agenda I have been exposing for 30 years is now being openly promoted by Cult assets like Gates and Klaus Schwab of the World Economic Forum under code-terms like the 'Great Reset', 'Build Back Better' and 'a rare but narrow window of opportunity to reflect, reimagine, and reset our world'. What provided this 'rare but narrow window of opportunity'? The 'Covid' hoax did. Who created that? *They* did. My books from not that long ago warned about the planned 'Internet of Things' (IoT) and its implications for human freedom. This was the plan to connect all technology to the Internet and artificial intelligence and today we are way down that road with an estimated 36 billion devices connected to the World Wide Web and that figure is projected to be 76 billion by 2025. I further warned that the Cult planned to go beyond that to the Internet of *Everything* when the human brain was connected via AI to the Internet and Kurzweil's 'cloud'. Now we have Cult operatives like Schwab calling for precisely that under the term 'Internet of Bodies', a fusion of the physical, digital and biological into one centrally-controlled Smart Grid system which the Cult refers to as the 'Fourth Industrial Revolution'. They talk about the 'biological', but they really mean the synthetic-biological which is required to fully integrate the human body and brain into the Smart Grid and artificial intelligence planned to replace the human mind. We have everything being synthetically manipulated including the natural world through GMO and smart dust, the food we eat and the human body itself with synthetic 'vaccines'. I said in *The Answer* that we would see the Cult push for synthetic meat to replace animals and in February, 2021, the so predictable psychopath Bill Gates called for the introduction of synthetic meat to save us all from 'climate change'. The climate hoax just keeps on giving like the 'Covid' hoax. The war on meat by vegan activists is a carbon (oops, sorry) copy of the manipulation of transgender activists. They have no idea (except their inner core) that they are being used to promote and impose the agenda of the Cult or that they are only the *vehicle* and not the *reason*. This is not to say those who choose not to eat meat shouldn't be respected and supported in that right, but there are ulterior motives for those in power. A *Forbes* article in December, 2019, highlighted the plan so beloved of Schwab and the Cult under the heading: 'What Is The Internet of Bodies? And How Is It Changing Our World?' The article said the human body is the latest data platform (remember 'our vaccine is an operating system'). *Forbes* described the plan very accurately and the words could have come straight out of my books from long before:

> The Internet of Bodies (IoB) is an extension of the IoT and basically connects the human body to a network through devices that are ingested, implanted, or connected to the body in some way. Once connected, data can be exchanged, and the body and device can be remotely monitored and controlled.

They were really describing a human hive mind with human perception centrally-dictated via an AI connection as well as allowing people to be 'remotely monitored and controlled'. Everything from a fridge to a human mind could be directed from a central point by these insane psychopaths and 'Covid vaccines' are crucial to this. Forbes explained the process I mentioned earlier of holdable and wearable technology followed by implantable. The article said there were three generations of the Internet of Bodies that include:

- Body external: These are wearable devices such as Apple Watches or Fitbits that can monitor our health.

- Body internal: These include pacemakers, cochlear implants, and digital pills that go inside our bodies to monitor or control various aspects of health.

- Body embedded: The third generation of the Internet of Bodies is embedded technology where technology and the human body are melded together and have a real-time connection to a remote machine.

Forbes noted the development of the Brain Computer Interface (BCI) which merges the brain with an external device for monitoring and controlling in real-time. 'The ultimate goal is to help restore function to individuals with disabilities by using brain signals rather than conventional neuromuscular pathways.' Oh, do fuck off. The goal of brain interface technology is controlling human thought and emotion from the central point in a hive mind serving its masters wishes. Many people are now agreeing to be chipped to open doors without a key. You can recognise them because they'll be wearing a mask, social distancing and lining up for the 'vaccine'. The Cult plans a Great Reset money system after they have completed the demolition of the global economy in which 'money' will be exchanged through communication with body operating systems. Rand Corporation, a Cult-owned think tank, said of the Internet of Bodies or IoB:

> Internet of Bodies technologies fall under the broader IoT umbrella. But as the name suggests, IoB devices introduce an even more intimate interplay between humans and gadgets. IoB devices monitor the human body, collect health metrics and other personal information, and transmit those data over the Internet. Many devices, such as fitness trackers, are already in use … IoB devices … and those in development can track, record, and store users' whereabouts, bodily functions, and what they see, hear, and even think.

Schwab's World Economic Forum, a long-winded way of saying 'fascism' or 'the Cult', has gone full-on with the Internet of Bodies in the 'Covid' era. 'We're entering the era of the Internet of Bodies', it declared, 'collecting our physical data via a range of devices that can be implanted, swallowed or worn'. The result would be a huge amount of health-related data that could improve human wellbeing around the world, and prove crucial in fighting the 'Covid-19 pandemic'. Does anyone think these clowns care about 'human wellbeing' after the death and devastation their pandemic hoax has purposely caused? Schwab and co say we should move forward with the Internet of Bodies because 'Keeping track of symptoms could help us stop the spread of infection, and quickly detect new cases'. How wonderful, but keeping track' is all they are really bothered about. Researchers were investigating if data gathered from smartwatches and similar devices could be used as viral infection alerts by tracking the user's heart rate and breathing. Schwab said in his 2018 book *Shaping the Future of the Fourth Industrial Revolution*:

> The lines between technologies and beings are becoming blurred and not just by the ability to create lifelike robots or synthetics. Instead it is about the ability of new technologies to literally become part of us. Technologies already influence how we understand ourselves, how we think about each other, and how we determine our realities. As the technologies … give us deeper access to parts of ourselves, we may begin to integrate digital technologies into our bodies.

You can see what the game is. Twenty-four hour control and people – if you could still call them that – would never know when something would go ping and take them out of circulation. It's the most obvious rush to a global fascist dictatorship and the complete submission of humanity and yet still so many are locked away in their Cult-induced perceptual coma and can't see it.

Smart Grid control centres

The human body is being transformed by the 'vaccines' and in other ways into a synthetic cyborg that can be attached to the global Smart Grid which would be controlled from a central point and other sub-locations of Grid manipulation. Where are these planned to be? Well, China for a start which is one of the Cult's biggest centres of operation. The technological control system and technocratic rule was incubated here to be unleashed across the world after the 'Covid' hoax came out of China in 2020. Another Smart Grid location that will surprise people new to this is Israel. I have exposed in *The Trigger* how Sabbatian technocrats, intelligence and military operatives were behind the horrors of 9/11 and not '19 Arab hijackers' who somehow manifested the ability to pilot big passenger airliners when instructors at puddle-jumping flying schools described some of them as a joke. The 9/11 attacks were made possible through control of civilian and military air computer systems and those of the White House, Pentagon and connected agencies. See *The Trigger* – it will blow your mind. The controlling and coordinating force were the Sabbatian networks in Israel and the United States which by then had infiltrated the entire US government, military and intelligence system. The real name of the American Deep State is 'Sabbatian State'. Israel is a tiny country of only nine million people, but it is one of the global centres of cyber operations and fast catching Silicon Valley in importance to the Cult. Israel is known as the 'start-up nation' for all the cyber companies spawned there with the Sabbatian specialisation of 'cyber security' that I mentioned earlier which gives those companies access to computer systems of their clients in real time through 'backdoors' written into the coding when security software is downloaded. The Sabbatian centre of cyber operations outside Silicon Valley is the Israeli military Cyber Intelligence Unit, the biggest infrastructure project in Israel's history, headquartered in the desert-city of Beersheba and involving some 20,000 'cyber soldiers'. Here are located a literal army of Internet trolls scanning social media, forums and comment lists for anyone challenging the Cult agenda. The UK military has something similar with its 77th Brigade and associated operations. The Beersheba complex includes research and development centres for other Cult operations such as Intel, Microsoft, IBM, Google, Apple, Hewlett-Packard, Cisco Systems, Facebook and Motorola. Techcrunch.com ran an article about the Beersheba global Internet technology centre headlined 'Israel's desert city of Beersheba is turning into a cybertech oasis':

> The military's massive relocation of its prestigious technology units, the presence of multinational and local companies, a close proximity to Ben Gurion University and generous government subsidies are turning Beersheba into a major global cybertech hub. Beersheba has all of the ingredients of a vibrant security technology ecosystem, including Ben Gurion University with its graduate program in cybersecurity and Cyber Security Research Center, and the presence of companies such as EMC, Deutsche Telekom, PayPal, Oracle, IBM, and Lockheed Martin. It's also the future home of the INCB (Israeli National Cyber Bureau); offers a special income tax incentive for cyber security companies, and was the site for the relocation of the army's intelligence corps units.

Sabbatians have taken over the cyber world through the following process: They scan the schools for likely cyber talent and develop them at Ben Gurion University and their period of conscription in the Israeli Defense Forces when they are stationed at the Beersheba complex. When the cyber talented officially leave the army they are funded to start cyber companies with technology developed by themselves or given to them by the state. Much of this is stolen through backdoors of computer systems around the world with America top of the list. Others are sent off to Silicon Valley to start companies or join the major ones and so we have many major positions filled by apparently 'Jewish' but really Sabbatian operatives. Google, YouTube and Facebook are all run by 'Jewish' CEOs while Twitter is all but run by ultra-Zionist hedge-fund shark Paul Singer. At the centre of the Sabbatian global cyber web is the Israeli army's Unit 8200 which specialises in hacking into computer systems of other countries, inserting viruses, gathering information, instigating malfunction, and even taking control of them from a distance. A long list of Sabbatians involved with 9/11, Silicon Valley and Israeli cyber security companies are operatives of Unit 8200. This is not about Israel. It's about the Cult. Israel is planned to be a Smart Grid hub as with China and what is happening at Beersheba is not for the benefit of Jewish people who are treated disgustingly by the Sabbatian elite that control the country. A glance at the Nuremberg Codes will tell you that.

The story is much bigger than 'Covid', important as that is to where we are being taken. Now, though, it's time to really strap in. There's more … much more …

CHAPTER ELEVEN

Who controls the Cult?

Awake, arise or be forever fall'n
John Milton, *Paradise Lost*

I have exposed this far the level of the Cult conspiracy that operates in the world of the seen and within the global secret society and satanic network which operates in the shadows one step back from the seen. The story, however, goes much deeper than that.

The 'Covid' hoax is major part of the Cult agenda, but only part, and to grasp the biggest picture we have to expand our attention beyond the realm of human sight and into the infinity of possibility that we cannot see. It is from here, ultimately, that humanity is being manipulated into a state of total control by the force which dictates the actions of the Cult. How much of reality can we see? Next to damn all is the answer. We may appear to see all there is to see in the 'space' our eyes survey and observe, but little could be further from the truth. The human 'world' is only a tiny band of frequency that the body's visual and perceptual systems can decode into *perception* of a 'world'. According to mainstream science the electromagnetic spectrum is 0.005 percent of what exists in the Universe (Fig 10). The maximum estimate I have seen is 0.5 percent and either way it's miniscule. I say it is far, far, smaller even than 0.005 percent when you compare reality we see with the totality of reality that we don't. Now get this if you are new to such information: Visible light, the only band of frequency that we can see, is a *fraction* of the 0.005

percent (Fig 11 overleaf). Take this further and realise that our universe is one of infinite universes and that universes are only a fragment of overall reality – *infinite* reality. Then compare that with the almost infinitesimal frequency band of visible light or human sight. You see that humans are as near blind as it is possible to be without actually being so. Artist and filmmaker, Sergio Toporek, said:

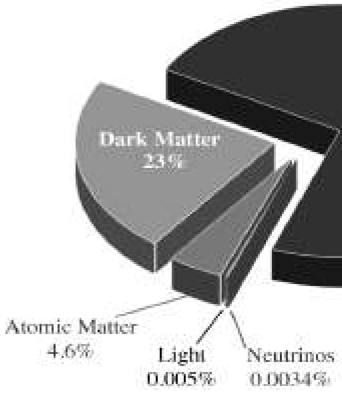

Figure 10: Humans can perceive such a tiny band of visual reality it's laughable.

Figure 11: We can see a smear of the 0.005 percent electromagnetic spectrum, but we still know it all. Yep, makes sense.

Consider that you can see less than 1% of the electromagnetic spectrum and hear less than 1% of the acoustic spectrum. 90% of the cells in your body carry their own microbial DNA and are not 'you'. The atoms in your body are 99.9999999999999999% empty space and none of them are the ones you were born with ... Human beings have 46 chromosomes, two less than a potato.

The existence of the rainbow depends on the conical photoreceptors in your eyes; to animals without cones, the rainbow does not exist. So you don't just look at a rainbow, you create it. This is pretty amazing, especially considering that all the beautiful colours you see represent less than 1% of the electromagnetic spectrum.

Suddenly the 'world' of humans looks a very different place. Take into account, too, that Planet Earth when compared with the projected size of this single universe is the equivalent of a billionth of a pinhead. Imagine the ratio that would be when compared to infinite reality. To think that Christianity once insisted that Earth and humanity were the centre of everything. This background is vital if we are going to appreciate the nature of 'human' and how we can be manipulated by an unseen force. To human visual reality virtually *everything* is unseen and yet the prevailing perception within the institutions and so much of the public is that if we can't see it, touch it, hear it, taste it and smell it then it cannot exist. Such perception is indoctrinated and encouraged by the Cult and its agents because it isolates believers in the strictly limited, village-idiot, realm of the five senses where perceptions can be firewalled and information controlled. Most of those perpetuating the 'this-world-is-all-there-is' insanity are themselves indoctrinated into believing the same delusion. While major players and influencers know that official reality is laughable most of those in science, academia and medicine really believe the nonsense they peddle and teach succeeding generations. Those who challenge the orthodoxy are dismissed as nutters and freaks to protect the manufactured illusion from exposure. Observe the dynamic of the 'Covid' hoax and you will see how that takes the same form. The inner-circle psychopaths knows it's a gigantic scam, but almost the entirety of those imposing their fascist rules believe that 'Covid' is all that they're told it is.

Stolen identity

Ask people who they are and they will give you their name, place of birth, location, job, family background and life story. Yet that is not who they are – it is what they are *experiencing*. The difference is *absolutely crucial*. The true 'I', the eternal, infinite 'I', is consciousness, a state of being aware. Forget 'form'. That is a vehicle for a brief experience. Consciousness does not come *from* the brain, but *through* the brain and even that is more symbolic than literal. We are awareness, pure awareness, and this is what withdraws from the body at what we call 'death' to continue our eternal beingness, *isness*, in other realms of reality within the limitlessness of infinity or the Biblical 'many mansions in my father's house'. Labels of a human life, man, woman, transgender, black, white, brown, nationality, circumstances and income are not who we are. They are what we are – awareness – is *experiencing* in a brief connection with a band of frequency we call 'human'. The labels are not the self; they are, to use the title of one of my books, a *Phantom* Self. I am not David Icke born in Leicester, England, on April 29th, 1952. I am the consciousness *having that experience*. The Cult and its non-human masters seek to convince us through the institutions of 'education', science, medicine, media and government that what we are *experiencing* is who we *are*. It's so easy to control and direct perception locked away in the bewildered illusions of the five senses with no expanded radar. Try, by contrast, doing the same with a humanity aware of its true self and its true power to consciously create its reality and experience. How is it possible to do this? We do it all day every day. If you perceive yourself as 'little me' with no power to impact upon your life and the world then your life experience will reflect that. You will hand the power you don't think you have to authority in all its forms which will use it to control your experience. This, in turn, will appear to confirm your perception of 'little me' in a self-fulfilling feedback loop. But that is what 'little me' really is – a *perception*. We are all 'big-me', infinite me, and the Cult has to make us forget that if its will is to prevail. We are therefore manipulated and pressured into self-identifying with human labels and not the consciousness/awareness *experiencing* those human labels.

The phenomenon of identity politics is a Cult-instigated manipulation technique to sub-divide previous labels into even smaller ones. A United States university employs this list of letters to describe student identity: LGBTTQQFAGPBDSM or lesbian, gay, bisexual, transgender, transsexual, queer, questioning, flexual, asexual, gender-fuck, polyamorous, bondage/discipline, dominance/submission and sadism/masochism. I'm sure other lists are even longer by now as people feel the need to self-identity the 'I' with the minutiae of race and sexual preference. Wokers programmed by the Cult for generations believe this is about 'inclusivity' when it's really the Cult locking them away into smaller and smaller versions of Phantom Self while firewalling them from the influence of their true self, the infinite, eternal 'I'. You may notice that my philosophy which contends that we are all unique points of attention/awareness within the same infinite whole or Oneness is the ultimate non-racism. The very sense of Oneness makes the judgement of people by their body-type, colour or sexuality utterly ridiculous and confirms that racism has no understanding of reality (including anti-white racism). Yet despite my perception of life Cult agents and fast-asleep Wokers label me racist to discredit my information while they are themselves phenomenally racist and sexist. All they see is race and sexuality and they judge people as good or bad, demons or untouchables, by their race and sexuality. All they see is *Phantom Self* and perceive themselves in terms of Phantom Self. They are pawns and puppets of the Cult agenda to focus attention and self-identity in the five senses and play those identities against each other to divide and rule. Columbia University has introduced segregated graduations in another version of social distancing designed to drive people apart and teach them that different racial and cultural groups have nothing in common with each other. The last thing the Cult wants is unity. Again the pump-primers of this will be Cult operatives in the knowledge of what they are doing, but the rest are just the Phantom Self blind leading the Phantom Self blind. We *do* have something in common – we are all *the same consciousness* having different temporary experiences.

What is this 'human'?

Yes, what *is* 'human'? That is what we are supposed to be, right? I mean 'human'? True, but 'human' is the experience not the 'I'. Break it down to basics and 'human' is the way that information is processed. If we are to experience and interact with this band of frequency we call the 'world' we must have a vehicle that operates within that band of frequency. Our consciousness in its prime form cannot do that; it is way beyond the frequency of the human realm. My consciousness or awareness could not tap these keys and pick up the cup in front of me in the same way that radio station A cannot interact with radio station B when they are on different frequencies. The human body is the means through which we have that interaction. I have long described the body as a biological computer which processes information in a way that allows consciousness to experience this reality. The body is a receiver, transmitter and processor of information in a particular way that we call human. We visually perceive only the world of the five senses in a wakened state – that is the limit of the body's visual decoding system. In truth it's not even visual in the way we experience 'visual reality' as I will come to in a moment. We are 'human' because the body processes the information sources of human into a reality and behaviour system that we *perceive* as human. Why does an elephant act like an elephant and not like a human or a duck? The elephant's biological computer is a different information field and processes information according to that program into a visual and behaviour type we call an elephant. The same applies to everything in our reality. These body information fields are perpetuated through procreation (like making a copy of a software program). The Cult wants to break that cycle and intervene technologically to transform the human information field into one that will change what we call humanity. If it can change the human information field it will change the way that field processes information and change humanity both 'physically' and psychologically. Hence the *messenger* (information) RNA 'vaccines' and so much more that is targeting human genetics by changing the body's information – *messaging* – construct through food, drink, radiation, toxicity and other means.

Reality that we experience is nothing like reality as it really is in the same way that the reality people experience in virtual reality games is not the reality they are really living in. The game is only a decoded source of information that appears to be a reality. Our world is also an information construct – a *simulation* (more later). In its base form our reality is a wavefield of information much the same in theme as Wi-Fi. The five senses decode wavefield information into electrical information which they communicate to the brain to decode into holographic (illusory 'physical') information. Different parts of the brain specialise in decoding different senses and the information is fused into a reality that appears to be outside of us but is really inside the brain and the genetic structure in general (Fig 12 overleaf). DNA is a receiver-transmitter of information and a vital part of this decoding process and the body's connection to other realities. Change DNA and you change the way we decode and connect with reality – see 'Covid vaccines'. Think of computers decoding Wi-Fi. You have information encoded in a radiation field and the computer decodes that information into a very different form on the screen. You can't see the Wi-Fi until its information is made manifest on the screen and the information on the screen is inside the computer and not outside. I have just described how we decode the 'human world'. All five senses decode the waveform 'Wi-Fi' field into electrical signals and the brain (computer) constructs reality inside the brain and not outside – 'You don't just look at a rainbow, you create it'. Sound is a simple example. We don't hear sound until the brain decodes it. Waveform sound waves are picked up by the hearing sense and communicated to the brain in an electrical form to be decoded into the sounds that we hear. Everything we hear is inside the brain along with everything we see, feel, smell and taste. Words and language are waveform fields generated by our vocal chords which pass through this process until they are decoded by the brain into words that we hear. Different languages are different frequency fields or sound waves generated by vocal chords. Late British philosopher Alan Watts said:

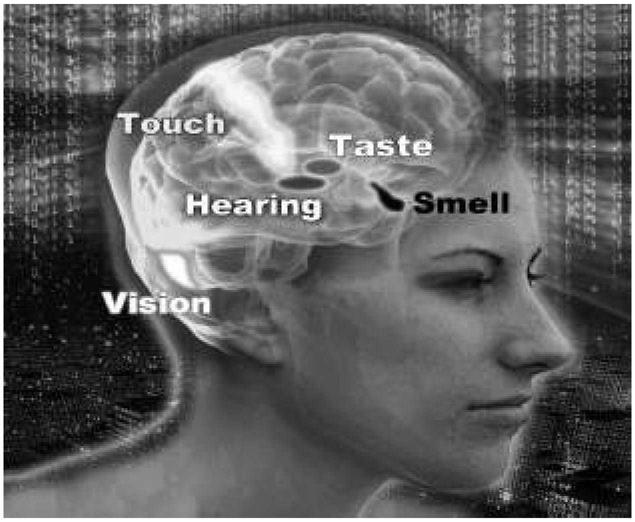

Figure 12: The brain receives information from the five senses and constructs from that our perceived reality.

> [Without the brain] the world is devoid of light, heat, weight, solidity, motion, space, time or any other imaginable feature. All these phenomena are interactions, or transactions, of vibrations with a certain arrangement of neurons.

That's exactly what they are and scientist Robert Lanza describes in his book, *Biocentrism*, how we decode electromagnetic waves and energy into visual and 'physical' experience. He uses the example of a flame emitting photons, electromagnetic energy, each pulsing electrically and magnetically:

> … these … invisible electromagnetic waves strike a human retina, and if (and only if) the waves happen to measure between 400 and 700 nano meters in length from crest to crest, then their energy is just right to deliver a stimulus to the 8 million cone-shaped cells in the retina.
>
> Each in turn send an electrical pulse to a neighbour neuron, and on up the line this goes, at 250 mph, until it reaches the … occipital lobe of the brain, in the back of the head. There, a cascading complex of neurons fire from the incoming stimuli, and we subjectively perceive this experience as a yellow brightness occurring in a place we have been conditioned to call the 'external world'.

You hear what you decode

If a tree falls or a building collapses they make no noise unless someone is there to decode the energetic waves generated by the disturbance into what we call sound. Does a falling tree make a noise? Only if you hear it – *decode* it. Everything in our reality is a frequency field of information operating within the overall 'Wi-Fi' field that I call The Field. A vibrational disturbance is generated in The Field by the fields of the falling tree or building. These disturbance waves are what we decode into the sound of them falling. If no one is there to do that then neither will make any noise. Reality is created by the observer – *decoder* – and the *perceptions* of the observer affect the decoding process. For this reason different people – different *perceptions* – will perceive the same reality or situation in a different way. What one may perceive as a nightmare another will see as an opportunity. The question of why the Cult is so focused on controlling human perception now answers itself. All experienced reality is the act of decoding and we don't experience Wi-Fi until it is decoded on the computer screen. The sight and sound of an Internet video is encoded in the Wi-Fi all around us, but we don't see or hear it until the computer decodes that information. Taste, smell and touch are all phenomena of the brain as a result of the same process. We don't taste, smell or feel anything except in the brain and there are pain relief techniques that seek to block the signal from the site of discomfort to the brain because if the brain doesn't decode that signal we don't feel pain. Pain is in the brain and only appears to be at the point of impact thanks to the feedback loop between them. We don't see anything until electrical information from the sight senses is decoded in an area at the back of the brain. If that area is damaged we can go blind when our eyes are perfectly okay. So why do we go blind if we damage an eye? We damage the information processing between the waveform visual information and the visual decoding area of the brain. If information doesn't reach the brain in a form it can decode then we can't see the visual reality that it represents. What's more the brain is decoding only a fraction of the information it receives and the rest is absorbed by the sub-conscious mind. This explanation is from the science magazine, *Wonderpedia*:

> Every second, 11 million sensations crackle along these [brain] pathways … The brain is confronted with an alarming array of images, sounds and smells which it rigorously filters down until it is left with a manageable list of around 40. Thus 40 sensations per second make up what we perceive as reality.

The 'world' is not what people are told to believe that is it and the inner circles of the Cult *know that*.

Illusory 'physical' reality

We can only see a smear of 0.005 percent of the Universe which is only one of a vast array of universes – 'mansions' – within infinite reality. Even then the brain decodes only 40 pieces of information ('sensations') from a potential *11 million* that we receive every second. Two points strike you from this immediately: The sheer breathtaking stupidity of believing we know anything so rigidly that there's nothing more to know; and the potential for these processes to be manipulated by a malevolent force to control the reality of the population. One thing I can say for sure with no risk of contradiction is that when you can perceive an almost indescribable fraction of infinite reality there is always more to know as in tidal waves of it. Ancient Greek philosopher Socrates was so right when he said that wisdom is to know how little we know. How obviously true that is when you think that we are experiencing a physical world of solidity that is neither physical nor solid and a world of apartness when everything is connected. Cult-controlled 'science' dismisses the so-called 'paranormal' and all phenomena related to that when the 'para'-normal is perfectly normal and explains the alleged 'great mysteries' which dumbfound scientific minds. There is a reason for this. A 'scientific mind' in terms of the mainstream is a material mind, a five-sense mind imprisoned in see it, touch it, hear it, smell it and taste it. Phenomena and happenings that can't be explained that way leave the 'scientific mind' bewildered and the rule is that if they can't account for why something is happening then it can't, by definition, be happening. I beg to differ. Telepathy is thought waves passing through The Field (think wave disturbance again) to be decoded by someone able to connect with that wavelength (information). For example: You can pick up the thought waves of a friend at any distance and at the very least that will bring them to mind. A few minutes later the friend calls you. 'My god', you say, 'that's incredible – I was just thinking of you.' Ah, but *they* were thinking of *you* before they made the call and that's what you decoded. Native peoples not entrapped in five-sense reality do this so well it became known as the 'bush telegraph'. Those known as psychics and mediums (genuine ones) are doing the same only across dimensions of reality. 'Mind over matter' comes from the fact that matter and mind are the *same*. The state of one influences the state of the other. Indeed one *and* the other are illusions. They are aspects of the same field. Paranormal phenomena are all explainable so why are they still considered 'mysteries' or not happening? Once you go down this road of understanding you begin to expand awareness beyond the five senses and that's the nightmare for the Cult.

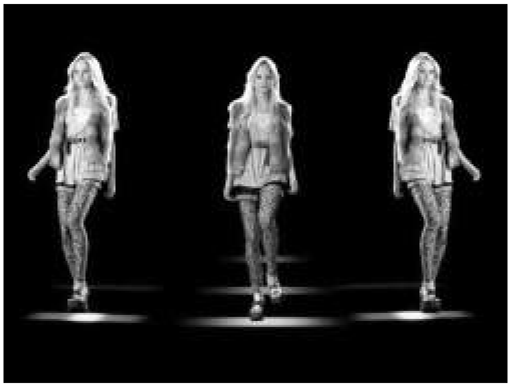

Figure 13: Holograms are not solid, but the best ones appear to be.

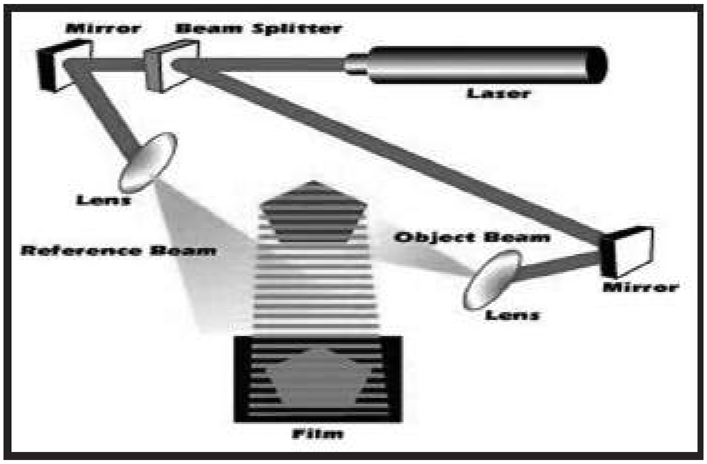

Figure 14: How holograms are created by capturing a waveform version of the subject image.

Holographic 'solidity'

Our reality is not solid, it is holographic. We are now well aware of holograms which are widely used today. Two-dimensional information is decoded into a three-dimensional reality that is not solid although can very much appear to be (Fig 13). Holograms are created with a laser divided into two parts. One goes directly onto a holographic photographic print ('reference beam') and the other takes a waveform image of the subject ('working beam') before being directed onto the print where it 'collides' with the other half of the laser (Fig 14). This creates a *waveform* interference pattern which contains the wavefield information of whatever is being photographed (Fig 15 overleaf). The process can be likened to dropping pebbles in a pond. Waves generated by each one spread out across the water to collide with the others and create a wave representation of where the stones fell and at what speed, weight and distance. A waveform interference pattern of a hologram is akin to the waveform information in The Field which the five senses decode into electrical signals to be decoded by the brain into a holographic illusory 'physical' reality. In the same way when a laser (think human attention) is directed at the waveform interference pattern a three-dimensional version of the subject is projected into apparently 'solid' reality (Fig 16). An amazing trait of holograms reveals more 'paranormal mysteries'. Information of the *whole* hologram is encoded in waveform in every part of the interference pattern by the way they are created. This means that every *part* of a hologram is a smaller version of the whole. Cut the interference wave-pattern into four and you won't get four parts of the image. You get quarter-sized versions of the *whole* image. The body is a hologram and the same applies. Here we have the basis of acupuncture, reflexology and other forms of healing which identify representations of the whole body in all of the parts, hands, feet, ears, everywhere. Skilled palm readers can do what they do because the information of whole body is encoded in the hand. The concept of as above, so below, comes from this.

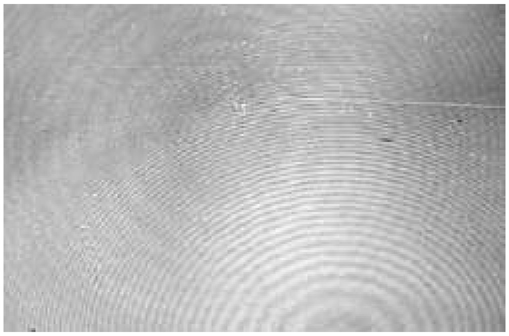

Figure 15: A waveform interference pattern that holds the information that transforms into a hologram.

She isn't really standing there
WILLIAM VIA HOLOGRAM
PERFORMER & OBAMA SUPPORTER
LIVE

Figure 16: Holographic people including 'Elvis' holographically inserted to sing a duet with Celine Dion.

The question will be asked of why, if solidity is illusory, we can't just walk through walls and each other. The resistance is not solid against solid; it is electromagnetic field against electromagnetic field and we decode this into the *experience* of solid against solid. We should also not underestimate the power of belief to dictate reality. What you believe is impossible *will be*. Your belief impacts on your decoding processes and they won't decode what you think is impossible. What we believe we perceive and what we perceive we experience. 'Can't dos' and 'impossibles' are like a firewall in a computer system that won't put on the screen what the firewall blocks. How vital that is to understanding how human experience has been hijacked. I explain in *The Answer*, *Everything You Need To Know But Have Never Been Told* and other books a long list of 'mysteries' and 'paranormal' phenomena that are not mysterious and perfectly normal once you realise what reality is and how it works. 'Ghosts' can be seen to pass through 'solid' walls because the walls are not solid and the ghost is a discarnate entity operating on a frequency so different to that of the wall that it's like two radio stations sharing the same space while never interfering with each other. I have seen ghosts do this myself. The apartness of people and objects is also an illusion. Everything is connected by the Field like all sea life is connected by the sea. It's just that within the limits of our visual reality we only 'see' holographic information and not the field of information that connects everything and from which the holographic world is made manifest. If you can only see holographic 'objects' and not the field that connects them they will appear to you as unconnected to each other in the same way that we see the computer while not seeing the Wi-Fi.

What you don't know *can* hurt you

Okay, we return to those 'two worlds' of human society and the Cult with its global network of interconnecting secret societies and satanic groups which manipulate through governments, corporations, media, religions, etc. The fundamental difference between them is *knowledge*. The idea has been to keep humanity ignorant of the plan for its total enslavement underpinned by a crucial ignorance of reality – who we are and where we are – and how we interact with it. 'Human' should be the interaction between our expanded eternal consciousness and the five-sense body experience. We are meant to be *in* this world in terms of the five senses but not *of* this world in relation to our greater consciousness and perspective. In that state we experience the small picture of the five senses within the wider context of the big picture of awareness beyond the five senses. Put another way the five senses see the dots and expanded awareness connects them into pictures and patterns that give context to the apparently random and unconnected. Without the context of expanded awareness the five senses see only apartness and randomness with apparently no meaning. The Cult and its other-dimensional controllers seek to intervene in the frequency realm where five-sense reality is supposed to connect with expanded reality and to keep the two apart (more on this in the final chapter). When that happens five-sense mental and emotional processes are no longer influenced by expanded awareness, or the True 'I', and instead are driven by the isolated perceptions of the body's decoding systems. They are in the world *and* of it. Here we have the human plight and why humanity with its potential for infinite awareness can be so easily manipulatable and descend into such extremes of stupidity.

Once the Cult isolates five-sense mind from expanded awareness it can then program the mind with perceptions and beliefs by controlling information that the mind receives through the 'education' system of the formative years and the media perceptual bombardment and censorship of an entire lifetime. Limit perception and a sense of the possible through limiting knowledge by limiting and skewing information while censoring and discrediting that which could set people free. As the title of another of my books says *… And The Truth Shall Set You Free*. For this reason the last thing the Cult wants in circulation is the truth about anything – especially the reality of the eternal 'I' – and that's why it is desperate to control information. The Cult knows that information becomes perception which becomes behaviour which, collectively, becomes human society. Cult-controlled and funded mainstream 'science' denies the existence of an eternal 'I' and seeks to dismiss and trash all evidence to the contrary. Cult-controlled mainstream religion has a version of 'God' that is little more than a system of control and dictatorship that employs threats of damnation in an afterlife to control perceptions and behaviour in the here and now through fear and guilt. Neither is true and it's the 'neither' that the Cult wishes to suppress. This 'neither' is that everything is an expression, a point of attention, within an infinite state of consciousness which is the real meaning of the term 'God'.

Perceptual obsession with the 'physical body' and five-senses means that 'God' becomes personified as a bearded bloke sitting among the clouds or a raging bully who loves us if we do what 'he' wants and condemns us to the fires of hell if we don't. These are no more than a 'spiritual' fairy tales to control and dictate events and behaviour through fear of this 'God' which has bizarrely made 'God-fearing' in religious circles a state to be desired. I would suggest that fearing *anything* is not to be encouraged and celebrated, but rather deleted. You can see why 'God fearing' is so beneficial to the Cult and its religions when *they* decide what 'God' wants and what 'God' demands (the Cult demands) that everyone do. As the great American comedian Bill Hicks said satirising a Christian zealot: 'I think what God meant to say.' How much of this infinite awareness ('God') that we access is decided by how far we choose to expand our perceptions, self-identity and sense of the possible. The scale of self-identity reflects itself in the scale of awareness that we can connect with and are influenced by – how much knowing and insight we have instead of programmed perception. You cannot expand your awareness into the infinity of possibility when you believe that you are little me Peter the postman or Mary in marketing and nothing more. I'll deal with this in the concluding chapter because it's crucial to how we turnaround current events.

Where the Cult came from

When I realised in the early 1990s there was a Cult network behind global events I asked the obvious question: When did it start? I took it back to ancient Rome and Egypt and on to Babylon and Sumer in Mesopotamia, the 'Land Between Two Rivers', in what we now call Iraq. The two rivers are the Tigris and Euphrates and this region is of immense historical and other importance to the Cult, as is the land called Israel only 550 miles away by air. There is much more going with deep esoteric meaning across this whole region. It's not only about 'wars for oil'. Priceless artefacts from Mesopotamia were stolen or destroyed after the American and British invasion of Iraq in 2003 justified by the lies of Boy Bush and Tony Blair (their Cult masters) about non-existent 'weapons of mass destruction'. Mesopotamia was the location of Sumer (about 5,400BC to 1,750BC), and Babylon (about 2,350BC to 539BC). Sabbatians may have become immensely influential in the Cult in modern times but they are part of a network that goes back into the mists of history. Sumer is said by historians to be the 'cradle of civilisation'. I disagree. I say it was the re-start of what we call human civilisation after cataclysmic events symbolised in part as the 'Great Flood' destroyed the world that existed before. These fantastic upheavals that I have been describing in detail in the books since the early1990s appear in accounts and legends of ancient cultures across the world and they are supported by geological and biological evidence. Stone tablets found in Iraq detailing the Sumer period say the cataclysms were caused by non-human 'gods' they call the Anunnaki. These are described in terms of extraterrestrial visitations in which knowledge supplied by the Anunnaki is said to have been the source of at least one of the world's oldest writing systems and developments in astronomy, mathematics and architecture that were way ahead of their time. I have covered this subject at length in *The Biggest Secret* and *Children of the Matrix* and the same basic 'Anunnaki' story can be found in Zulu accounts in South Africa where the late and very great Zulu high shaman Credo Mutwa told me that the Sumerian Anunnaki were known by Zulus as the Chitauri or 'children of the serpent'. See my six-hour video interview with Credo on this subject entitled *The*

Reptilian Agenda recorded at his then home near Johannesburg in 1999 which you can watch on the Ickonic media platform.

The Cult emerged out of Sumer, Babylon and Egypt (and elsewhere) and established the Roman Empire before expanding with the Romans into northern Europe from where many empires were savagely imposed in the form of Cult-controlled societies all over the world. Mass death and destruction was their calling card. The Cult established its centre of operations in Europe and European Empires were Cult empires which allowed it to expand into a global force. Spanish and Portuguese colonialists headed for Central and South America while the British and French targeted North America. Africa was colonised by Britain, France, Belgium, the Netherlands, Portugal, Spain, Italy, and Germany. Some like Britain and France moved in on the Middle East. The British Empire was by far the biggest for a simple reason. By now Britain was the headquarters of the Cult from which it expanded to form Canada, the United States, Australia and New Zealand. The Sun never set on the British Empire such was the scale of its occupation. London remains a global centre for the Cult along with Rome and the Vatican although others have emerged in Israel and China. It is no accident that the 'virus' is alleged to have come out of China while Italy was chosen as the means to terrify the Western population into compliance with 'Covid' fascism. Nor that Israel has led the world in 'Covid' fascism and mass 'vaccination'.

You would think that I would mention the United States here, but while it has been an important means of imposing the Cult's will it is less significant than would appear and is currently in the process of having what power it does have deleted. The Cult in Europe has mostly loaded the guns for the US to fire. America has been controlled from Europe from the start through Cult operatives in Britain and Europe. The American Revolution was an illusion to make it appear that America was governing itself while very different forces were pulling the strings in the form of Cult families such as the Rothschilds through the Rockefellers and other subordinates. The Rockefellers are extremely close to Bill Gates and established both scalpel and drug 'medicine' and the World Health Organization. They play a major role in the development and circulation of vaccines through the Rockefeller Foundation on which Bill Gates said his Foundation is based. Why wouldn't this be the case when the Rockefellers and Gates are on the same team? Cult infiltration of human society goes way back into what we call history and has been constantly expanding and centralising power with the goal of establishing a global structure to dictate everything. Look how this has been advanced in great leaps with the 'Covid' hoax.

The non-human dimension

I researched and observed the comings and goings of Cult operatives through the centuries and even thousands of years as they were born, worked to promote the agenda within the secret society and satanic networks, and then died for others to replace them. Clearly there had to be a coordinating force that spanned this entire period while operatives who would not have seen the end goal in their lifetimes came and went advancing the plan over millennia. I went in search of that coordinating force with the usual support from the extraordinary synchronicity of my life which has been an almost daily experience since 1990. I saw common themes in religious texts and ancient cultures about a non-human force manipulating human society from the hidden. Christianity calls this force Satan, the Devil and demons; Islam refers to the Jinn or Djinn; Zulus have their Chitauri (spelt in other ways in different parts of Africa); and the Gnostic people in Egypt in the period around and before 400AD referred to this phenomena as the 'Archons', a word meaning rulers in Greek. Central American cultures speak of the 'Predators' among other names and the same theme is everywhere. I will use 'Archons' as a collective name for all of them. When you see how their nature and behaviour is described all these different sources are clearly talking about the same force. Gnostics described the Archons in terms of 'luminous fire' while Islam relates the Jinn to 'smokeless fire'. Some refer to beings in form that could occasionally be seen, but the most common of common theme is that they operate from unseen realms which means almost all existence to the visual processes of humans. I had concluded that this was indeed the foundation of human control and that the Cult was operating within the human frequency band on behalf of this hidden force when I came across the writings of Gnostics which supported my conclusions in the most extraordinary way.

A sealed earthen jar was found in 1945 near the town of Nag Hammadi about 75-80 miles north of Luxor on the banks of the River Nile in Egypt. Inside was a treasure trove of manuscripts and texts left by the Gnostic people some 1,600 years earlier. They included 13 leather-bound papyrus codices (manuscripts) and more than 50 texts written in Coptic Egyptian estimated to have been hidden in the jar in the period of 400AD although the source of the information goes back much further. Gnostics oversaw the Great or Royal Library of Alexandria, the fantastic depository of ancient texts detailing advanced knowledge and accounts of human history. The Library was dismantled and destroyed in stages over a long period with the death-blow delivered by the Cult-established Roman Church in the period around 415AD. The Church of Rome was the Church of Babylon relocated as I said earlier. Gnostics were not a race. They were a way of perceiving reality. Whenever they established themselves and their information circulated the terrorists of the Church of Rome would target them for destruction. This happened with the Great Library and with the Gnostic Cathars who were burned to death by the psychopaths after a long period of oppression at the siege of the Castle of Monségur in southern France in 1244. The Church has always been terrified of Gnostic information which demolishes the official Christian narrative although there is much in the Bible that supports the Gnostic view if you read it in another way. To anyone studying the texts of what became known as the Nag Hammadi Library it is clear that great swathes of Christian and Biblical belief has its origin with Gnostics sources going back to Sumer. Gnostic themes have been twisted to manipulate the perceived reality of Bible believers. Biblical texts have been in the open for centuries where they could be changed while Gnostic documents found at Nag Hammadi were sealed away and untouched for 1,600 years. What you see is what they wrote.

Use your *pneuma* not your *nous*

Gnosticism and Gnostic come from 'gnosis' which means knowledge, or rather *secret* knowledge, in the sense of spiritual awareness – knowledge about reality and life itself. The desperation of the Cult's Church of Rome to destroy the Gnostics can be understood when the knowledge they were circulating was the last thing the Cult wanted the population to know. Sixteen hundred years later the same Cult is working hard to undermine and silence me for the same reason. The dynamic between knowledge and ignorance is a constant. 'Time' appears to move on, but essential themes remain the same. We are told to 'use your nous', a Gnostic word for head/brain/intelligence. They said, however, that spiritual awakening or 'salvation' could only be secured by expanding awareness *beyond* what they called *nous* and into *pneuma* or Infinite Self. Obviously as I read these texts the parallels with what I have been saying since 1990 were fascinating to me. There is a universal truth that spans human history and in that case why wouldn't we be talking the same language 16 centuries apart? When you free yourself from the perception program of the five senses and explore expanded realms of consciousness you are going to connect with the same information no matter what the perceived 'era' within a manufactured timeline of a single and tiny range of manipulated frequency. Humans working with 'smart' technology or knocking rocks together in caves is only a timeline appearing to operate within the human frequency band. Expanded awareness and the knowledge it holds have always been there whether the era be Stone Age or computer age. We can only access that knowledge by opening ourselves to its frequency which the five-sense prison cell is designed to stop us doing. Gates, Fauci, Whitty, Vallance, Zuckerberg, Brin, Page, Wojcicki, Bezos, and all the others behind the 'Covid' hoax clearly have a long wait before their range of frequency can make that connection given that an open heart is crucial to that as we shall see. Instead of accessing knowledge directly through expanded awareness it is given to Cult operatives by the secret society networks of the Cult where it has been passed on over thousands of years outside the public arena. Expanded realms of consciousness is where great artists, composers and writers find their inspiration and where truth awaits anyone open enough to connect with it. We need to go there fast.

Archon hijack

A fifth of the Nag Hammadi texts describe the existence and manipulation of the Archons led by a 'Chief Archon' they call 'Yaldabaoth', or the 'Demiurge', and this is the Christian 'Devil', 'Satan', 'Lucifer', and his demons. Archons in Biblical symbolism are the 'fallen ones' which are also referred to as fallen angels after the angels expelled from heaven according to the Abrahamic religions of Judaism, Christianity and Islam. These angels are claimed to tempt humans to 'sin' ongoing and you will see how accurate that symbolism is during the rest of the book. The theme of 'original sin' is related to the 'Fall' when Adam and Eve were 'tempted by the serpent' and fell from a state of innocence and 'obedience' (connection) with God into a state of disobedience (disconnection). The Fall is said to have brought sin into the world and corrupted everything including human nature. Yaldabaoth, the 'Lord Archon', is described by Gnostics as a 'counterfeit spirit', 'The Blind One', 'The Blind God', and 'The Foolish One'. The Jewish name for Yaldabaoth in Talmudic writings is Samael which translates as 'Poison of God', or 'Blindness of God'. You see the parallels. Yaldabaoth in Islamic belief is the Muslim Jinn devil known as Shaytan – Shaytan is Satan as the same themes are found all over the world in every religion and culture. The 'Lord God' of the Old Testament is the 'Lord Archon' of Gnostic manuscripts and that's why he's such a bloodthirsty bastard. Satan is known by Christians as 'the Demon of Demons' and Gnostics called Yaldabaoth the 'Archon of Archons'. Both are known as 'The Deceiver'. We are talking about the same 'bloke' for sure and these common themes using different names, storylines and symbolism tell a common tale of the human plight.

Archons are referred to in Nag Hammadi documents as mind parasites, inverters, guards, gatekeepers, detainers, judges, pitiless ones and deceivers. The 'Covid' hoax alone is a glaring example of all these things. The Biblical 'God' is so different in the Old and New Testaments because they are not describing the same phenomenon. The vindictive, angry, hate-filled, 'God' of the Old Testament, known as Yahweh, is Yaldabaoth who is depicted in Cult-dictated popular culture as the 'Dark Lord', 'Lord of Time', Lord (Darth) Vader and Dormammu, the evil ruler of the 'Dark Dimension' trying to take over the 'Earth Dimension' in the Marvel comic movie, *Dr Strange*. Yaldabaoth is both the Old Testament 'god' and the Biblical 'Satan'. Gnostics referred to Yaldabaoth as the 'Great Architect of the Universe'and the Cult-controlled Freemason network calls their god 'the 'Great Architect of the Universe' (also Grand Architect). The 'Great Architect' Yaldabaoth is symbolised by the Cult as the all-seeing eye at the top of the pyramid on the Great Seal of the United States and the dollar bill. Archon is encoded in *arch*-itect as it is in *arch*-angels and *arch*-bishops. All religions have the theme of a force for good and force for evil in some sort of spiritual war and there is a reason for that – the theme is true. The Cult and its non-human masters are quite happy for this to circulate. They present themselves as the force for good fighting evil when they are really the force of evil (absence of love). The whole foundation of Cult modus operandi is inversion. They promote themselves as a force for good and anyone challenging them in pursuit of peace, love, fairness, truth and justice is condemned as a satanic force for evil. This has been the game plan throughout history whether the Church of Rome inquisitions of non-believers or 'conspiracy theorists' and 'anti-vaxxers' of today. The technique is the same whatever the timeline era.

Yaldabaoth is revolting (true)

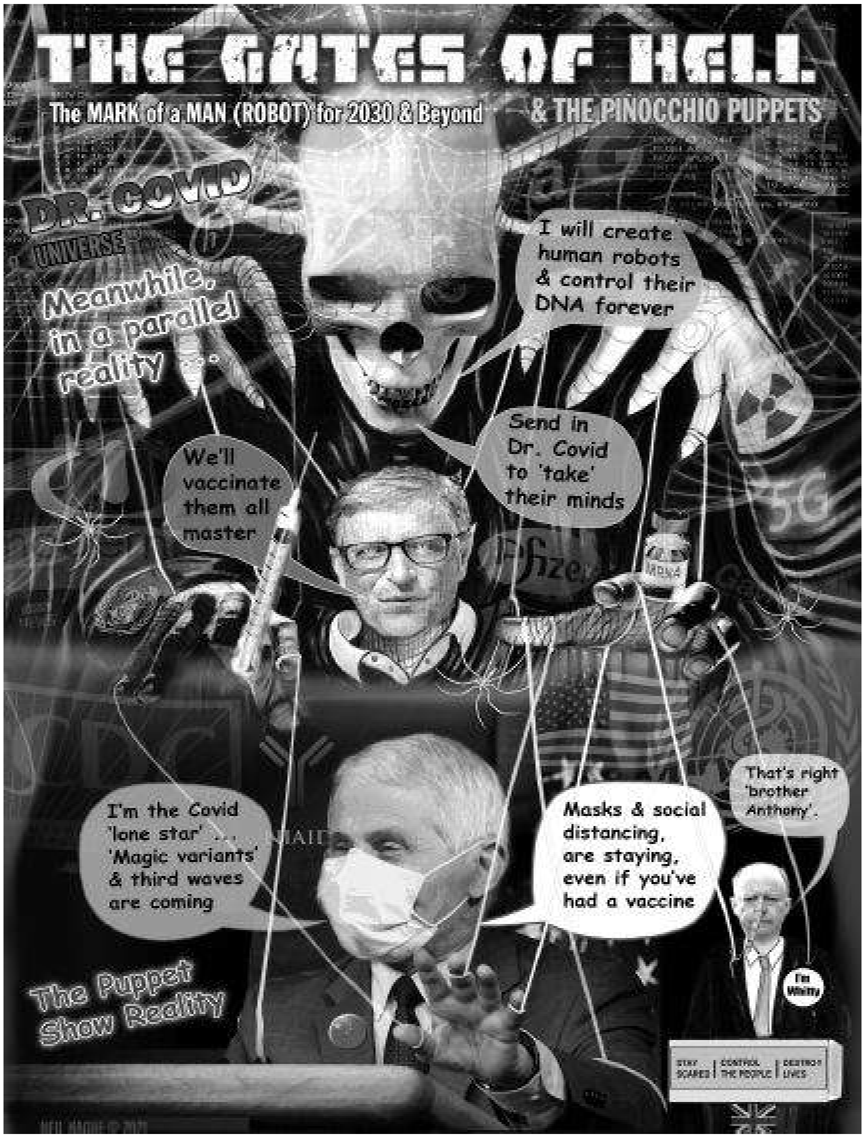
Yaldabaoth and the Archons are said to have revolted against God with Yaldabaoth claiming to *be* God – the *All That Is*. The Old Testament 'God' (Yaldabaoth) demanded to be worshipped as such: '*I am* the LORD, and there is none else, there is no God beside me' (Isaiah 45:5). I have quoted in other books a man who said he was the unofficial son of the late Baron Philippe de Rothschild of the Mouton-Rothschild wine producing estates in France who died in 1988 and he told me about the Rothschild 'revolt from God'. The man said he was given the name Phillip Eugene de Rothschild and we shared long correspondence many years ago while he was living under another identity. He said that he was conceived through 'occult incest' which (within the Cult) was 'normal and to be admired'. 'Phillip' told me about his experience attending satanic rituals with rich and famous people whom he names and you can see them and the wider background to Cult Satanism in my other books starting with *The Biggest Secret*. Cult rituals are interactions with Archontic 'gods'. 'Phillip' described Baron Philippe de Rothschild as 'a master Satanist and hater of God' and he used the same term 'revolt from God' associated with Yaldabaoth/Satan/Lucifer/the Devil in describing the Sabbatian Rothschild dynasty. 'I played a key role in my family's revolt from God', he said. That role was to infiltrate in classic Sabbatian style the Christian Church, but eventually he escaped the mind-prison to live another life. The Cult has been targeting religion in a plan to make worship of the Archons the global one-world religion. Infiltration of Satanism into modern 'culture', especially among the young, through music videos, stage shows and other means, is all part of this.

Nag Hammadi texts describe Yaldabaoth and the Archons in their prime form as energy – consciousness – and say they can take form if they choose in the same way that consciousness takes form as a human. Yaldabaoth is called 'formless' and represents a deeply inverted, distorted and chaotic state of consciousness which seeks to attached to humans and turn them into a likeness of itself in an attempt at assimilation. For that to happen it has to manipulate humans into low frequency mental and emotional states that match its own. Archons can certainly appear in human form and this is the origin of the psychopathic personality. The energetic distortion Gnostics called Yaldabaoth *is* psychopathy. When psychopathic Archons take human form that human will be a psychopath as an expression of Yaldabaoth consciousness. Cult psychopaths are Archons in human form. The principle is the same as that portrayed in the 2009 *Avatar* movie when the American military travelled to a fictional Earth-like moon called Pandora in the Alpha Centauri star system to infiltrate a society of blue people, or Na'vi, by hiding within bodies that looked like the Na'vi. Archons posing as humans have a particular hybrid information field, part human, part Archon, (the ancient 'demigods') which processes information in a way that manifests behaviour to match their psychopathic evil, lack of empathy and compassion, and stops them being influenced by the empathy, compassion and love that a fully-human information field is capable of expressing. Cult bloodlines interbreed, be they royalty or dark suits, for this reason and you have their obsession with incest. Interbreeding with full-blown humans would dilute the Archontic energy field that guarantees psychopathy in its representatives in the human realm.

Gnostic writings say the main non-human forms that Archons take are *serpentine* (what I have called for decades 'reptilian' amid unbounded ridicule from the Archontically-programmed) and what Gnostics describe as 'an unborn baby or foetus with grey skin and dark, unmoving eyes'. This is an excellent representation of the ET 'Greys' of UFO folklore which large numbers of people claim to have seen and been abducted by – Zulu shaman Credo Mutwa among them. I agree with those that believe in extraterrestrial or interdimensional visitations today and for thousands of years past. No wonder with their advanced knowledge and technological capability they were perceived and worshipped as gods for technological and other 'miracles' they appeared to perform. Imagine someone arriving in a culture disconnected from the modern world with a smartphone and computer. They would be seen as a ‘god’ capable of ‘miracles’. The Renegade Mind, however, wants to know the source of everything and not only the way that source manifests as human or non-human. In the same way that a Renegade Mind seeks the original source material for the ‘Covid virus’ to see if what is claimed is true. The original source of Archons in form is consciousness – the distorted state of consciousness known to Gnostics as Yaldabaoth.

‘Revolt from God’ is energetic disconnection

Where I am going next will make a lot of sense of religious texts and ancient legends relating to ‘Satan’, Lucifer’ and the ‘gods’. Gnostic descriptions sync perfectly with the themes of my own research over the years in how they describe a consciousness distortion seeking to impose itself on human consciousness. I’ve referred to the core of infinite awareness in previous books as Infinite Awareness in Awareness of Itself. By that I mean a level of awareness that knows that it is all awareness and is aware of all awareness. From here comes the frequency of love in its true sense and balance which is what love is on one level – the balance of all forces into a single whole called Oneness and Isness. The more we disconnect from this state of love that many call ‘God’ the constituent parts of that Oneness start to unravel and express themselves as a part and not a whole. They become individualised as intellect, mind, selfishness, hatred, envy, desire for power over others, and such like. This is not a problem in the greater scheme in that ‘God’, the *All That Is*, can experience all these possibilities through different expressions of itself including humans. What we as expressions of the whole experience the *All That Is* experiences. We are the *All That Is* experiencing itself. As we withdraw from that state of Oneness we disconnect from its influence and things can get very unpleasant and very stupid. Archontic consciousness is at the extreme end of that. It has so disconnected from the influence of Oneness that it has become an inversion of unity and love, an inversion of everything, an inversion of life itself. Evil is appropriately live written backwards. Archontic consciousness is obsessed with death, an inversion of life, and so its manifestations in Satanism are obsessed with death. They use inverted symbols in their rituals such as the inverted pentagram and cross. Sabbatians as Archontic consciousness incarnate invert Judaism and every other religion and culture they infiltrate. They seek disunity and chaos and they fear unity and harmony as they fear love like garlic to a vampire. As a result the Cult, Archons incarnate, act with such evil, psychopathy and lack of empathy and compassion disconnected as they are from the source of love. How could Bill Gates and the rest of the Archontic psychopaths do what they have to human society in the 'Covid' era with all the death, suffering and destruction involved and have no emotional consequence for the impact on others? Now you know. Why have Zuckerberg, Brin, Page, Wojcicki and company callously censored information warning about the dangers of the 'vaccine' while thousands have been dying and having severe, sometimes life-changing reactions? Now you know. Why have Tedros, Fauci, Whitty, Vallance and their like around the world been using case and death figures they're aware are fraudulent to justify lockdowns and all the deaths and destroyed lives that have come from that? Now you know. Why did Christian Drosten produce and promote a 'testing' protocol that he knew couldn't test for infectious disease which led to a global human catastrophe. Now you know. The Archontic mind doesn't give a shit (Fig 17). I personally think that Gates and major Cult insiders are a form of AI cyborg that the Archons want humans to become.



THE GATES OF HELL
The MARK of a MAN (ROBOT) for 2030 & Beyond
& THE PINOCCHIO PUPPETS
DR. COVID
UNIVERSE
Meanwhile, in a parallel reality . . .
I will create human robots & control their DNA forever
Send in Dr. Covid to 'take' their minds
We'll vaccinate them all master
5G
Pfizer
I'm the Covid 'lone star' ... 'Magic variants' & third waves are coming
NIAID
Masks & social distancing, are staying, even if you've had a vaccine
That's right 'brother Anthony'.

Human batteries

A state of such inversion does have its consequences, however. The level of disconnection from the Source of All means that you withdraw from that source of energetic sustenance and creativity. This means that you have to find your own supply of energetic power and it has – *us*. When the Morpheus character in the first *Matrix* movie held up a battery he spoke a profound truth when he said: 'The Matrix is a computer-generated dream world built to keep us under control in order to change the human being into one of these.' The statement was true in all respects. We do live in a technologically-generated virtual reality simulation (more very shortly) and we have been manipulated to be an energy source for Archontic consciousness. The Disney-Pixar animated movie *Monsters, Inc*. in 2001 symbolised the dynamic when monsters in their world had no energy source and they would enter the human world to terrify children in their beds, catch the child's scream, terror (low-vibrational frequencies), and take that energy back to power the monster world. The lead character you might remember was a single giant eye and the symbolism of the Cult's all-seeing eye was obvious. Every thought and emotion is broadcast as a frequency unique to that thought and emotion. Feelings of love and joy, empathy and compassion, are high, quick, frequencies while fear, depression, anxiety, suffering and hate are low, slow, dense frequencies. Which kind do you think Archontic consciousness can connect with and absorb? In such a low and dense frequency state there's no way it can connect with the energy of love and joy. Archons can only feed off energy compatible with their own frequency and they and their Cult agents want to delete the human world of love and joy and manipulate the transmission of low vibrational frequencies through low-vibrational human mental and emotional states. *We are their energy source*. Wars are energetic banquets to the Archons – a world war even more so – and think how much low-frequency mental and emotional energy has been generated from the consequences for humanity of the 'Covid' hoax orchestrated by Archons incarnate like Gates.

The ancient practice of human sacrifice 'to the gods', continued in secret today by the Cult, is based on the same principle. 'The gods' are Archontic consciousness in different forms and the sacrifice is induced into a state of intense terror to generate the energy the Archontic frequency can absorb. Incarnate Archons in the ritual drink the blood which contains an adrenaline they crave which floods into the bloodstream when people are terrorised. Most of the sacrifices, ancient and modern, are children and the theme of 'sacrificing young virgins to the gods' is just code for children. They have a particular pre-puberty energy that Archons want more than anything and the energy of the young in general is their target. The California Department of Education wants students to chant the names of Aztec gods (Archontic gods) once worshipped in human sacrifice rituals in a curriculum designed to encourage them to ‘challenge racist, bigoted, discriminatory, imperialist/colonial beliefs’, join ‘social movements that struggle for social justice’, and ‘build new possibilities for a post-racist, post-systemic racism society’. It’s the usual Woke crap that inverts racism and calls it anti-racism. In this case solidarity with ‘indigenous tribes’ is being used as an excuse to chant the names of ‘gods’ to which people were sacrificed (and still are in secret). What an example of Woke’s inability to see beyond black and white, us and them, They condemn the colonisation of these tribal cultures by Europeans (quite right), but those cultures sacrificing people including children to their ‘gods’, and mass murdering untold numbers as the Aztecs did, is just fine. One chant is to the Aztec god Tezcatlipoca who had a man sacrificed to him in the 5th month of the Aztec calendar. His heart was cut out and he was eaten. Oh, that’s okay then. Come on children … after three … Other sacrificial ‘gods’ for the young to chant their allegiance include Quetzalcoatl, Huitzilopochtli and Xipe Totec. The curriculum says that ‘chants, affirmations, and energizers can be used to bring the class together, build unity around ethnic studies principles and values, and to reinvigorate the class following a lesson that may be emotionally taxing or even when student engagement may appear to be low’. Well, that’s the cover story, anyway. Chanting and mantras are the repetition of a particular frequency generated from the vocal cords and chanting the names of these Archontic ‘gods’ tunes you into their frequency. That is the last thing you want when it allows for energetic synchronisation, attachment and perceptual influence. Initiates chant the names of their ‘Gods’ in their rituals for this very reason.

Vampires of the Woke

Paedophilia is another way that Archons absorb the energy of children. Paedophiles possessed by Archontic consciousness are used as the conduit during sexual abuse for discarnate Archons to vampire the energy of the young they desire so much. Stupendous numbers of children disappear every year never to be seen again although you would never know from the media. Imagine how much low-vibrational energy has been generated by children during the 'Covid' hoax when so many have become depressed and psychologically destroyed to the point of killing themselves. Shocking numbers of children are now taken by the state from loving parents to be handed to others. I can tell you from long experience of researching this since 1996 that many end up with paedophiles and assets of the Cult through corrupt and Cult-owned social services which in the reframing era has hired many psychopaths and emotionless automatons to do the job. Children are even stolen to order using spurious reasons to take them by the corrupt and secret (because they're corrupt) 'family courts'. I have written in detail in other books, starting with *The Biggest Secret* in 1997, about the ubiquitous connections between the political, corporate, government, intelligence and military elites (Cult operatives) and Satanism and paedophilia. If you go deep enough both networks have an interlocking leadership. The Woke mentality has been developed by the Cult for many reasons: To promote almost every aspect of its agenda; to hijack the traditional political left and turn it fascist; to divide and rule; and to target agenda pushbackers. But there are other reasons which relate to what I am describing here. How many happy and joyful Wokers do you ever see especially at the extreme end? They are a mental and psychological mess consumed by emotional stress and constantly emotionally cocked for the next explosion of indignation at someone referring to a female as a female. They are walking, talking, batteries as Morpheus might say emitting frequencies which both enslave them in low-vibrational bubbles of perceptual limitation and feed the Archons. Add to this the hatred claimed to be love; fascism claimed to 'anti-fascism', racism claimed to be 'anti-racism';

exclusion claimed to inclusion; and the abuse-filled Internet trolling. You have a purpose-built Archontic energy system with not a wind turbine in sight and all founded on Archontic *inversion*. We have whole generations now manipulated to serve the Archons with their actions and energy. They will be doing so their entire adult lives unless they snap out of their Archon-induced trance. Is it really a surprise that Cult billionaires and corporations put so much money their way? Where is the energy of joy and laughter, including laughing at yourself which is confirmation of your own emotional security? Mark Twain said: 'The human race has one really effective weapon, and that is laughter.' We must use it all the time. Woke has destroyed comedy because it has no humour, no joy, sense of irony, or self-deprecation. Its energy is dense and intense. *Mmmmm*, lunch says the Archontic frequency. Rudolf Steiner (1861-1925) was the Austrian philosopher and famous esoteric thinker who established Waldorf education or Steiner schools to treat children like unique expressions of consciousness and not minds to be programmed with the perceptions determined by authority. I'd been writing about this energy vampiring for decades when I was sent in 2016 a quote by Steiner. He was spot on:

> There are beings in the spiritual realms for whom anxiety and fear emanating from human beings offer welcome food. When humans have no anxiety and fear, then these creatures starve. If fear and anxiety radiates from people and they break out in panic, then these creatures find welcome nutrition and they become more and more powerful. These beings are hostile towards humanity. Everything that feeds on negative feelings, on anxiety, fear and superstition, despair or doubt, are in reality hostile forces in super-sensible worlds, launching cruel attacks on human beings, while they are being fed ... These are exactly the feelings that belong to contemporary culture and materialism; because it estranges people from the spiritual world, it is especially suited to evoke hopelessness and fear of the unknown in people, thereby calling up the above mentioned hostile forces against them.

Pause for a moment from this perspective and reflect on what has happened in the world since the start of 2020. Not only will pennies drop, but billion dollar bills. We see the same theme from Don Juan Matus, a Yaqui Indian shaman in Mexico and the information source for Peruvian-born writer, Carlos Castaneda, who wrote a series of books from the 1960s to 1990s. Don Juan described the force manipulating human society and his name for the Archons was the predator:

> We have a predator that came from the depths of the cosmos and took over the rule of our lives. Human beings are its prisoners. The predator is our lord and master. It has rendered us docile, helpless. If we want to protest, it suppresses our protest. If we want to act independently, it demands that we don't do so ... indeed we are held prisoner!
>
> They took us over because we are food to them, and they squeeze us mercilessly because we are their sustenance. Just as we rear chickens in coops, the predators rear us in human coops, humaneros. Therefore, their food is always available to them.

Different cultures, different eras, same recurring theme.

The 'ennoia' dilemma

Nag Hammadi Gnostic manuscripts say that Archon consciousness has no 'ennoia'. This is directly translated as 'intentionality', but I'll use the term 'creative imagination'. The *All That Is* in awareness of itself is the source of all creativity – all possibility – and the more disconnected you are from that source the more you are subsequently denied 'creative imagination'. Given that Archon consciousness is almost entirely disconnected it severely lacks creativity and has to rely on far more mechanical processes of thought and exploit the creative potential of those that do have 'ennoia'. You can see cases of this throughout human society. Archon consciousness almost entirely dominates the global banking system and if we study how that system works you will appreciate what I mean. Banks manifest 'money' out of nothing by issuing lines of 'credit' which is 'money' that has never, does not, and will never exist except in theory. It's a confidence trick. If you think 'credit' figures-on-a-screen 'money' is worth anything you accept it as payment. If you don't then the whole system collapses through lack of confidence in the value of that 'money'. Archontic bankers with no 'ennoia' are 'lending' 'money' that doesn't exist to humans that *do* have creativity – those that have the inspired ideas and create businesses and products. Archon banking feeds off human creativity which it controls through ‘money’ creation and debt. Humans have the creativity and Archons exploit that for their own benefit and control while having none themselves. Archon Internet platforms like Facebook claim joint copyright of everything that creative users post and while Archontic minds like Zuckerberg may officially head that company it will be human creatives on the staff that provide the creative inspiration. When you have limitless ‘money’ you can then buy other companies established by creative humans. Witness the acquisition record of Facebook, Google and their like. Survey the Archon-controlled music industry and you see non-creative dark suit executives making their fortune from the human creativity of their artists. The cases are endless. Research the history of people like Gates and Zuckerberg and how their empires were built on exploiting the creativity of others. Archon minds cannot create out of nothing, but they are skilled (because they have to be) in what Gnostic texts call ‘countermimicry’. They can imitate, but not innovate. Sabbatians trawl the creativity of others through backdoors they install in computer systems through their cybersecurity systems. Archon-controlled China is globally infamous for stealing intellectual property and I remember how Hong Kong, now part of China, became notorious for making counterfeit copies of the creativity of others – ‘countermimicry’. With the now pervasive and all-seeing surveillance systems able to infiltrate any computer you can appreciate the potential for Archons to vampire the creativity of humans. Author John Lamb Lash wrote in his book about the Nag Hammadi texts, *Not In His Image*:

> Although they cannot originate anything, because they lack the divine factor of ennoia (intentionality), Archons can imitate with a vengeance. Their expertise is simulation (HAL, virtual reality). The Demiurge [Yaldabaoth] fashions a heaven world copied from the fractal patterns [of the original] ... His construction is celestial kitsch, like the fake Italianate villa of a Mafia don complete with militant angels to guard every portal.

This brings us to something that I have been speaking about since the turn of the millennium. Our reality is a simulation; a virtual reality that we think is real. No, I’m not kidding.

Human reality? Well, virtually

I had pondered for years about whether our reality is ‘real’ or some kind of construct. I remembered being immensely affected on a visit as a small child in the late 1950s to the then newly-opened Planetarium on the Marylebone Road in London which is now closed and part of the adjacent Madame Tussauds wax museum. It was in the middle of the day, but when the lights went out there was the night sky projected in the Planetarium’s domed ceiling and it appeared to be so real. The experience never left me and I didn’t know why until around the turn of the millennium when I became certain that our ‘night sky’ and entire reality is a projection, a virtual reality, akin to the illusory world portrayed in the *Matrix* movies. I looked at the sky one day in this period and it appeared to me like the domed roof of the Planetarium. The release of the first *Matrix* movie in 1999 also provided a synchronistic and perfect visual representation of where my mind had been going for a long time. I hadn’t come across the Gnostic Nag Hammadi texts then. When I did years later the correlation was once again astounding. As I read Gnostic accounts from 1,600 years and more earlier it was clear that they were describing the same simulation phenomenon. They tell how the Yaldabaoth ‘Demiurge’ and Archons created a ‘bad copy’ of original reality to rule over all that were captured by its illusions and the body was a prison to trap consciousness in the ‘bad copy’ fake reality. Read how Gnostics describe the ‘bad copy’ and update that to current times and they are referring to what we would call today a virtual reality simulation.

Author John Lamb Lash said ‘the Demiurge fashions a heaven world copied from the fractal patterns’ of the original through expertise in ‘HAL’ or virtual reality simulation. Fractal patterns are part of the energetic information construct of our reality, a sort of blueprint. If these patterns were copied in computer terms it would indeed give you a copy of a ‘natural’ reality in a non-natural frequency and digital form. The principle is the same as making a copy of a website. The original website still exists, but now you can change the copy version to make it whatever you like and it can become very different to the original website. Archons have done this with our reality, a *synthetic* copy of prime reality that still exists beyond the frequency walls of the simulation. Trapped within the illusions of this synthetic Matrix, however, were and are human consciousness and other expressions of prime reality and this is why the Archons via the Cult are seeking to make the human body synthetic and give us synthetic AI minds to complete the job of turning the entire reality synthetic including what we perceive to be the natural world. To quote Kurzweil: 'Nanobots will infuse all the matter around us with information. Rocks, trees, everything will become these intelligent creatures.' Yes, *synthetic* 'creatures' just as 'Covid' and other genetically-manipulating 'vaccines' are designed to make the human body synthetic. From this perspective it is obvious why Archons and their Cult are so desperate to infuse synthetic material into every human with their 'Covid' scam.

Let there be (electromagnetic) light

Yaldabaoth, the force that created the simulation, or Matrix, makes sense of the Gnostic reference to 'The Great Architect' and its use by Cult Freemasonry as the name of its deity. The designer of the Matrix in the movies is called 'The Architect' and that trilogy is jam-packed with symbolism relating to these subjects. I have contended for years that the angry Old Testament God (Yaldabaoth) is the 'God' being symbolically 'quoted' in the opening of Genesis as 'creating the world'. This is not the creation of prime reality – it's the creation of the *simulation*. The Genesis 'God' says: 'Let there be Light: and there was light.' But what is this 'Light'? I have said for decades that the speed of light (186,000 miles per second) is not the fastest speed possible as claimed by mainstream science and is in fact the frequency walls or outer limits of the Matrix. You can't have a fastest or slowest anything within all possibility when everything is possible. The human body is encoded to operate within the speed of light or *within the simulation* and thus we see only the tiny frequency band of visible *light*. Near-death experiencers who perceive reality outside the body during temporary 'death' describe a very different form of light and this is supported by the Nag Hammadi texts. Prime reality beyond the simulation ('Upper Aeons' to the Gnostics) is described as a realm of incredible beauty, bliss, love and harmony – a realm of 'watery light' that is so powerful 'there are no shadows'. Our false reality of Archon control, which Gnostics call the 'Lower Aeons', is depicted as a realm with a different kind of 'light' and described in terms of chaos, 'Hell', 'the Abyss' and 'Outer Darkness', where trapped souls are tormented and manipulated by demons (relate that to the 'Covid' hoax alone). The watery light theme can be found in near-death accounts and it is not the same as *simulation* 'light' which is electromagnetic or radiation light within the speed of light – the 'Lower Aeons'. Simulation 'light' is the 'luminous fire' associated by Gnostics with the Archons. The Bible refers to Yaldabaoth as 'that old serpent, called the Devil, and Satan, which deceiveth the whole world' (Revelation 12:9). I think that making a simulated copy of prime reality ('countermimicry') and changing it dramatically while all the time manipulating humanity to believe it to be real could probably meet the criteria of deceiving the whole world. Then we come to the Cult god Lucifer – the *Light Bringer*. Lucifer is symbolic of Yaldabaoth, the bringer of radiation light that forms the bad copy simulation within the speed of light. 'He' is symbolised by the lighted torch held by the Statue of Liberty and in the name 'Illuminati'. Sabbatian-Frankism declares that Lucifer is the true god and Lucifer is the real god of Freemasonry honoured as their 'Great or Grand Architect of the Universe' (simulation).

I would emphasise, too, the way Archontic technologically-generated luminous fire of radiation has deluged our environment since I was a kid in the 1950s and changed the nature of The Field with which we constantly interact. Through that interaction technological radiation is changing us. The Smart Grid is designed to operate with immense levels of communication power with 5G expanding across the world and 6G, 7G, in the process of development. Radiation is the simulation and the Archontic manipulation system. Why wouldn't the Archon Cult wish to unleash radiation upon us to an ever-greater extreme to form

Kurzweil's 'cloud'? The plan for a synthetic human is related to the need to cope with levels of radiation beyond even anything we've seen so far. Biological humans would not survive the scale of radiation they have in their script. The Smart Grid is a technological sub-reality within the technological simulation to further disconnect five-sense perception from expanded consciousness. It's a technological prison of the mind.

Infusing the 'spirit of darkness'

A recurring theme in religion and native cultures is the manipulation of human genetics by a non-human force and most famously recorded as the biblical 'sons of god' (the god*s* plural in the original) who interbred with the daughters of men. The Nag Hammadi *Apocryphon of John* tells the same story this way:

> He [Yaldabaoth] sent his angels [Archons/demons] to the daughters of men, that they might take some of them for themselves and raise offspring for their enjoyment. And at first they did not succeed. When they had no success, they gathered together again and they made a plan together ... And the angels changed themselves in their likeness into the likeness of their mates, filling them with the spirit of darkness, which they had mixed for them, and with evil ... And they took women and begot children out of the darkness according to the likeness of their spirit.

Possession when a discarnate entity takes over a human body is an age-old theme and continues today. It's very real and I've seen it. Satanic and secret society rituals can create an energetic environment in which entities can attach to initiates and I've heard many stories of how people have changed their personality after being initiated even into lower levels of the Freemasons. I have been inside three Freemasonic temples, one at a public open day and two by just walking in when there was no one around to stop me. They were in Ryde, the town where I live, Birmingham, England, when I was with a group, and Boston, Massachusetts. They all felt the same energetically – dark, dense, low-vibrational and sinister. Demonic attachment can happen while the initiate has no idea what is going on. To them it's just a ritual to get in the Masons and do a bit of good business. In the far more extreme rituals of Satanism human possession is even more powerful and they are designed to make possession possible. The hierarchy of the Cult is dictated by the power and perceived status of the possessing Archon. In this way the Archon hierarchy becomes the Cult hierarchy. Once the entity has attached it can influence perception and behaviour and if it attaches to the extreme then so much of its energy (information) infuses into the body information field that the hologram starts to reflect the nature of the possessing entity. This is the *Exorcist* movie type of possession when facial features change and it's known as shapeshifting. Islam's Jinn are said to be invisible tricksters who change shape, 'whisper', confuse and take human form. These are all traits of the Archons and other versions of the same phenomenon. Extreme possession could certainty infuse the 'spirit of darkness' into a partner during sex as the Nag Hammadi texts appear to describe. Such an infusion can change genetics which is also energetic information. Human genetics is information and the 'spirit of darkness' is information. Mix one with the other and change must happen. Islam has the concept of a 'Jinn baby' through possession of the mother and by Jinn taking human form. There are many ways that human genetics can be changed and remember that Archons have been aware all along of advanced techniques to do this. What is being done in human society today – and far more – was known about by Archons at the time of the 'fallen ones' and their other versions described in religions and cultures.

Archons and their human-world Cult are obsessed with genetics as we see today and they know this dictates how information is processed into perceived reality during a human life. They needed to produce a human form that would decode the simulation and this is symbolically known as 'Adam and Eve' who left the 'garden' (prime reality) and 'fell' into Matrix reality. The simulation is not a 'physical' construct (there is no 'physical'); it is a source of information. Think Wi-Fi again. The simulation is an energetic field encoded with information and body-brain systems are designed to decode that information encoded in wave or frequency form which is transmitted to the brain as electrical signals. These are decoded by the brain to construct our sense of reality – an illusory 'physical' world that only exists in the brain or the mind. Virtual reality games mimic this process using the same sensory decoding system. Information is fed to the senses to decode a virtual reality that can appear so real, but isn't (Figs 18 and 19). Some scientists believe – and I agree with them – that what we perceive as 'physical' reality only exists when we are looking or observing. The act of perception or focus triggers the decoding systems which turn waveform information into holographic reality. When we are not observing something our reality reverts from a holographic state to a waveform state. This relates to the same principle as a falling tree not making a noise unless someone is there to hear it or decode it. The concept makes sense from the simulation perspective. A computer is not decoding all the information in a Wi-Fi field all the time and only decodes or brings into reality on the screen that part of Wi-Fi that it's decoding – focusing upon – at that moment.

Figure 18: Virtual reality technology 'hacks' into the body's five-sense decoding system.

Figure 19: The result can be experienced as very 'real'.

Interestingly, Professor Donald Hoffman at the Department of Cognitive Sciences at the University of California, Irvine, says that our experienced reality is like a computer interface that shows us only the level with which we interact while hiding all that exists beyond it: 'Evolution shaped us with a user interface that hides the truth. Nothing that we see is the truth – the very language of space and time and objects is the wrong language to describe reality.' He is correct in what he says on so many levels. Space and time are not a universal reality. They are a phenomenon of decoded *simulation* reality as part of the process of enslaving our sense of reality. Near-death experiencers report again and again how space and time did not exist as we perceive them once they were free of the body – body decoding systems. You can appreciate from this why Archons and their Cult are so desperate to entrap human attention in the five senses where we are in the Matrix and of the Matrix. Opening your mind to expanded states of awareness takes you beyond the information confines of the simulation and you become aware of knowledge and insights denied to you before. This is what we call 'awakening' – *awakening from the Matrix* – and in the final chapter I will relate this to current events.

Where are the 'aliens'?

A simulation would explain the so-called 'Fermi Paradox' named after Italian physicist Enrico Fermi (1901-1954) who created the first nuclear reactor. He considered the question of why there is such a lack of extraterrestrial activity when there are so many stars and planets in an apparently vast universe; but what if the night sky that we see, or think we do, is a simulated projection as I say? If you control the simulation and your aim is to hold humanity fast in essential ignorance would you want other forms of life including advanced life coming and going sharing information with humanity? Or would you want them to believe they were isolated and apparently alone? Themes of human isolation and apartness are common whether they be the perception of a lifeless universe or the fascist isolation laws of the 'Covid' era. Paradoxically the very existence of a simulation means that we are not alone when some force had to construct it. My view is that experiences that people have reported all over the world for centuries with Reptilians and Grey entities are Archon phenomena as Nag Hammadi texts describe; and that benevolent 'alien' interactions are non-human groups that come in and out of the simulation by overcoming Archon attempts to keep them out. It should be highlighted, too, that Reptilians and Greys are obsessed with *genetics* and *technology* as related by cultural accounts and those who say they have been abducted by them. Technology is their way of overcoming some of the limitations in their creative potential and our technology-driven and controlled human society of today is *arch*etypical Archon-Reptilian-Grey modus operandi. Technocracy is really *Archon*tocracy. The Universe does not have to be as big as it appears with a simulation. There is no space or distance only information decoded into holographic reality. What we call 'space' is only the absence of holographic 'objects' and that 'space' is The Field of energetic information which connects everything into a single whole. The same applies with the artificially-generated information field of the simulation. The Universe is not big or small as a physical reality. It is decoded information, that's all, and its perceived size is decided by the way the simulation is encoded to make it appear. The entire night sky as we perceive it only exists in our brain and so where are those 'millions of light years'? The 'stars' on the ceiling of the Planetarium looked a vast distance away.

There's another point to mention about 'aliens'. I have been highlighting since the 1990s the plan to stage a fake 'alien invasion' to justify the centralisation of global power and a world military. Nazi scientist Werner von Braun, who was taken to America by Operation Paperclip after World War Two to help found NASA, told his American assistant Dr Carol Rosin about the Cult agenda when he knew he was dying in 1977. Rosin said that he told her about a sequence that would lead to total human control by a one-world government. This included threats from terrorism, rogue nations, meteors and asteroids before finally an 'alien invasion'. All of these things, von Braun said, would be bogus and what I would refer to as a No-Problem-Reaction-Solution. Keep this in mind when 'the aliens are coming' is the new mantra. The aliens are not coming – they are *already here* and they have infiltrated human society while looking human. French-Canadian investigative journalist Serge Monast said in 1994 that he had uncovered a NASA/military operation called Project Blue Beam which fits with what Werner von Braun predicted. Monast died of a 'heart attack' in 1996 the day after he was arrested and spent a night in prison. He was 51. He said Blue Beam was a plan to stage an alien invasion that would include religious figures beamed holographically into the sky as part of a global manipulation to usher in a 'new age' of worshipping what I would say is the Cult 'god' Yaldabaoth in a one-world religion. Fake holographic asteroids are also said to be part of the plan which again syncs with von Braun. How could you stage an illusory threat from asteroids unless they were holographic inserts? This is pretty straightforward given the advanced technology outside the public arena and the fact that our 'physical' reality is holographic anyway. Information fields would be projected and we would decode them into the illusion of a 'physical' asteroid. If they can sell a global 'pandemic' with a 'virus' that doesn't exist what will humans not believe if government and media tell them?

All this is particularly relevant as I write with the Pentagon planning to release in June, 2021, information about 'UFO sightings'. I have been following the UFO story since the early 1990s and the common theme throughout has been government and military denials and cover up. More recently, however, the Pentagon has suddenly become more talkative and apparently open with Air Force pilot radar images released of unexplained craft moving and changing direction at speeds well beyond anything believed possible with human technology. Then, in March, 2021, former Director of National Intelligence John Ratcliffe said a Pentagon report months later in June would reveal a great deal of information about UFO sightings unknown to the public. He said the report would have 'massive implications'. The order to do this was included bizarrely in a $2.3 trillion 'coronavirus' relief and government funding bill passed by the Trump administration at the end of 2020. I would add some serious notes of caution here. I have been pointing out since the 1990s that the US military and intelligence networks have long had craft – 'flying saucers' or anti-gravity craft – which any observer would take to be extraterrestrial in origin. Keeping this knowledge from the public allows craft flown by *humans* to be perceived as alien visitations. I am not saying that 'aliens' do not exist. I would be the last one to say that, but we have to be streetwise here. President Ronald Reagan told the UN General Assembly in 1987: 'I occasionally think how quickly our differences worldwide would vanish if we were facing an alien threat from outside this world.' That's the idea. Unite against a common 'enemy' with a common purpose behind your 'saviour force' (the Cult) as this age-old technique of mass manipulation goes global.

Science moves this way ...

I could find only one other person who was discussing the simulation hypothesis publicly when I concluded it was real. This was Nick Bostrom, a Swedish-born philosopher at the University of Oxford, who has explored for many years the possibility that human reality is a computer simulation although his version and mine are not the same. Today the simulation and holographic reality hypothesis have increasingly entered the scientific mainstream. Well, the more open-minded mainstream, that is. Here are a few of the ever-gathering examples. American nuclear physicist Silas Beane led a team of physicists at the University of Bonn in Germany pursuing the question of whether we live in a simulation. They concluded that we probably do and it was likely based on a lattice of cubes. They found that cosmic rays align with that specific pattern. The team highlighted the Greisen–Zatsepin–Kuzmin (GZK) limit which refers to cosmic ray particle interaction with cosmic background radiation that creates an apparent boundary for cosmic ray particles. They say in a paper entitled 'Constraints on the Universe as a Numerical Simulation' that this 'pattern of constraint' is exactly what you would find with a computer simulation. They also made the point that a simulation would create its own 'laws of physics' that would limit possibility. I've been making the same point for decades that the *perceived* laws of physics relate only to this reality, or what I would later call the simulation. When designers write codes to create computer and virtual reality games they are the equivalent of the laws of physics for that game. Players interact within the limitations laid out by the coding. In the same way those who wrote the codes for the simulation decided the laws of physics that would apply. These can be overridden by expanded states of consciousness, but not by those enslaved in only five-sense awareness where simulation codes rule. Overriding the codes is what people call 'miracles'. They are not. They are bypassing the encoded limits of the simulation. A population caught in simulation perception would have no idea that this was their plight. As the Bonn paper said: 'Like a prisoner in a pitch-black cell we would not be able to see the "walls" of our prison,' That's true if people remain mesmerised by the five senses. Open to expanded awareness and those walls become very clear. The main one is the speed of light.

American theoretical physicist James Gates is another who has explored the simulation question and found considerable evidence to support the idea. Gates was Professor of Physics at the University of Maryland, Director of The Center for String and Particle Theory, and on Barack Obama's Council of Advisors on Science and Technology. He and his team found *computer codes* of digital data embedded in the fabric of our reality. They relate to on-off electrical charges of 1 and 0 in the binary system used by computers. 'We have no idea what they are doing there', Gates said. They found within the energetic fabric mathematical sequences known as error-correcting codes or block codes that 'reboot' data to its original state or 'default settings' when something knocks it out of sync. Gates was asked if he had found a set of equations embedded in our reality indistinguishable from those that drive search engines and browsers and he said: 'That is correct.' Rich Terrile, director of the Centre for Evolutionary Computation and Automated Design at NASA's Jet

Propulsion Laboratory, has said publicly that he believes the Universe is a digital hologram that must have been created by a form of intelligence. I agree with that in every way. Waveform information is delivered electrically by the senses to the brain which constructs a *digital* holographic reality that we call the 'world'. This digital level of reality can be read by the esoteric art of numerology. Digital holograms are at the cutting edge of holographics today. We have digital technology everywhere designed to access and manipulate our digital level of perceived reality. Synthetic mRNA in 'Covid vaccines' has a digital component to manipulate the body's digital 'operating system'.

Reality is numbers

How many know that our reality can be broken down to numbers and codes that are the same as computer games? Max Tegmark, a physicist at the Massachusetts Institute of Technology (MIT), is the author of *Our Mathematical Universe* in which he lays out how reality can be entirely described by numbers and maths in the way that a video game is encoded with the 'physics' of computer games. Our world and computer virtual reality are essentially the same. Tegmark imagines the perceptions of characters in an advanced computer game when the graphics are so good they don't know they are in a game. They think they can bump into real objects (electromagnetic resistance in our reality), fall in love and feel emotions like excitement. When they began to study the apparently 'physical world' of the video game they would realise that everything was made of pixels (which have been found in our energetic reality as must be the case when on one level our world is digital). What computer game characters thought was physical 'stuff', Tegmark said, could actually be broken down into numbers:

> And we're exactly in this situation in our world. We look around and it doesn't seem that mathematical at all, but everything we see is made out of elementary particles like quarks and electrons. And what properties does an electron have? Does it have a smell or a colour or a texture? No! ... We physicists have come up with geeky names for [Electron] properties, like

electric charge, or spin, or lepton number, but the electron doesn't care what we call it, the properties are just numbers.

This is the illusory reality Gnostics were describing. This is the simulation. The A, C, G, and T codes of DNA have a binary value – A and C = 0 while G and T = 1. This has to be when the simulation is digital and the body must be digital to interact with it. Recurring mathematical sequences are encoded throughout reality and the body. They include the Fibonacci sequence in which the two previous numbers are added to get the next one, as in ... 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, etc. The sequence is encoded in the human face and body, proportions of animals, DNA, seed heads, pine cones, trees, shells, spiral galaxies, hurricanes and the number of petals in a flower. The list goes on and on. There are fractal patterns – a 'never-ending pattern that is infinitely complex and self-similar across all scales in the as above, so below, principle of holograms. These and other famous recurring geometrical and mathematical sequences such as Phi, Pi, Golden Mean, Golden Ratio and Golden Section are *computer codes* of the simulation. I had to laugh and give my head a shake the day I finished this book and it went into the production stage. I was sent an article in *Scientific American* published in April, 2021, with the headline 'Confirmed! We Live in a Simulation'. Two decades after I first said our reality is a simulation and the speed of light is it's outer limit the article suggested that we do live in a simulation and that the speed of light is its outer limit. I left school at 15 and never passed a major exam in my life while the writer was up to his eyes in qualifications. As I will explain in the final chapter *knowing* is far better than thinking and they come from very different sources. The article rightly connected the speed of light to the processing speed of the 'Matrix' and said what has been in my books all this time … 'If we are in a simulation, as it appears, then space is an abstract property written in code. It is not real'. No it's not and if we live in a simulation something created it and it wasn't *us*. 'That David Icke says we are manipulated by aliens' – he's crackers.'

Wow …

The reality that humanity thinks is so real is an illusion. Politicians, governments, scientists, doctors, academics, law enforcement, media, school and university curriculums, on and on, are all founded on a world that *does not exist* except as a simulated prison cell. Is it such a stretch to accept that 'Covid' doesn't exist when our entire 'physical' reality doesn't exist? Revealed here is the knowledge kept under raps in the Cult networks of compartmentalised secrecy to control humanity's sense of reality by inducing the population to believe in a reality that's not real. If it wasn't so tragic in its experiential consequences the whole thing would be hysterically funny. None of this is new to Renegade Minds. Ancient Greek philosopher Plato (about 428 to about 347BC) was a major influence on Gnostic belief and he described the human plight thousands of years ago with his Allegory of the Cave. He told the symbolic story of prisoners living in a cave who had never been outside. They were chained and could only see one wall of the cave while behind them was a fire that they could not see. Figures walked past the fire casting shadows on the prisoners' wall and those moving shadows became their sense of reality. Some prisoners began to study the shadows and were considered experts on them (today's academics and scientists), but what they studied was only an illusion (today's academics and scientists). A prisoner escaped from the cave and saw reality as it really is. When he returned to report this revelation they didn't believe him, called him mad and threatened to kill him if he tried to set them free. Plato's tale is not only a brilliant analogy of the human plight and our illusory reality. It describes, too, the dynamics of the 'Covid' hoax. I have only skimmed the surface of these subjects here. The aim of this book is to crisply connect all essential dots to put what is happening today into its true context. All subject areas and their connections in this chapter are covered in great evidential detail in *Everything You Need To Know, But Have Never Been Told* and *The Answer*.

They say that bewildered people 'can't see the forest for the trees'. Humanity, however, can't see the forest for the *twigs*. The five senses see only twigs while Renegade Minds can see the forest and it’s the forest where the answers lie with the connections that reveals. Breaking free of perceptual programming so the forest can be seen is the way we turn all this around. Not breaking free is how humanity got into this mess. The situation may seem hopeless, but I promise you it’s not. We are a perceptual heartbeat from paradise if only we knew.

CHAPTER TWELVE

Escaping Wetiko

Life is simply a vacation from the infinite
Dean Cavanagh

Renegade Minds weave the web of life and events and see common themes in the apparently random. They are always there if you look for them and their pursuit is aided by incredible synchronicity that comes when your mind is open rather than mesmerised by what it thinks it can see.

Infinite awareness is infinite possibility and the more of infinite possibility that we access the more becomes infinitely possible. That may be stating the apparently obvious, but it is a devastatingly-powerful fact that can set us free. We are a point of attention within an infinity of consciousness. The question is how much of that infinity do we choose to access? How much knowledge, insight, awareness, wisdom, do we want to connect with and explore? If your focus is only in the five senses you will be influenced by a fraction of infinite awareness. I mean a range so tiny that it gives new meaning to infinitesimal. Limitation of self-identity and a sense of the possible limit accordingly your range of consciousness. We are what we think we are. Life is what we think it is. The dream is the dreamer and the dreamer is the dream. Buddhist philosophy puts it this way: 'As a thing is viewed, so it appears.' Most humans live in the realm of touch, taste, see, hear, and smell and that's the limit of their sense of the possible and sense of self. Many will follow a religion and speak of a God in his heaven, but their lives are still dominated by the five senses in their perceptions and actions. The five senses become the arbiter of everything. When that happens all except a smear of infinity is sealed away from influence by the rigid, unyielding, reality bubbles that are the five-sense human or Phantom Self. Archon Cult methodology is to isolate consciousness within five-sense reality – the simulation – and then program that consciousness with a sense of self and the world through a deluge of life-long information designed to instil the desired perception that allows global control. Efforts to do this have increased dramatically with identity politics as identity bubbles are squeezed into the minutiae of five-sense detail which disconnect people even more profoundly from the infinite 'I'.

Five-sense focus and self-identity are like a firewall that limits access to the infinite realms. You only perceive one radio or television station and no other. We'll take that literally for a moment. Imagine a vast array of stations giving different information and angles on reality, but you only ever listen to one. Here we have the human plight in which the population is overwhelmingly confined to CultFM. This relates only to the frequency range of CultFM and limits perception and insight to that band – limits *possibility* to that band. It means you are connecting with an almost imperceptibly minuscule range of possibility and creative potential within the infinite Field. It's a world where everything seems apart from everything else and where synchronicity is rare. Synchronicity is defined in the dictionary as 'the happening by chance of two or more related or similar events at the same time'. Use of 'by chance' betrays a complete misunderstanding of reality. Synchronicity is not 'by chance'. As people open their minds, or 'awaken' to use the term, they notice more and more coincidences in their lives, bits of 'luck', apparently miraculous happenings that put them in the right place at the right time with the right people. Days become peppered with 'fancy meeting you here' and 'what are the chances of that?' My entire life has been lived like this and ever more so since my own colossal awakening in 1990 and 91 which transformed my sense of reality. Synchronicity is not 'by chance'; it is by accessing expanded realms of possibility which allow expanded potential for manifestation. People broadcasting the same vibe from the same openness of mind tend to be drawn 'by chance' to each other through what I call frequency magnetism and it's not only people. In the last more than 30 years incredible synchronicity has also led me through the Cult maze to information in so many forms and to crucial personal experiences. These 'coincidences' have allowed me to put the puzzle pieces together across an enormous array of subjects and situations. Those who have breached the bubble of five-sense reality will know exactly what I mean and this escape from the perceptual prison cell is open to everyone whenever they make that choice. This may appear super-human when compared with the limitations of 'human', but it's really our natural state. 'Human' as currently experienced is consciousness in an unnatural state of induced separation from the infinity of the whole. I'll come to how this transformation into unity can be made when I have described in more detail the force that holds humanity in servitude by denying this access to infinite self.

The Wetiko factor

I have been talking and writing for decades about the way five-sense mind is systematically barricaded from expanded awareness. I have used the analogy of a computer (five-sense mind) and someone at the keyboard (expanded awareness). Interaction between the computer and the operator is symbolic of the interaction between five-sense mind and expanded awareness. The computer directly experiences the Internet and the operator experiences the Internet via the computer which is how it's supposed to be – the two working as one. Archons seek to control that point where the operator connects with the computer to stop that interaction (Fig 20). Now the operator is banging the keyboard and clicking the mouse, but the computer is not responding and this happens when the computer is taken over – *possessed* – by an appropriately-named computer 'virus'. The operator has lost all influence over the computer which goes its own way making decisions under the control of the 'virus'. I have just described the dynamic through which the force known to Gnostics as Yaldabaoth and Archons disconnects five-sense mind from expanded awareness to imprison humanity in perceptual servitude.

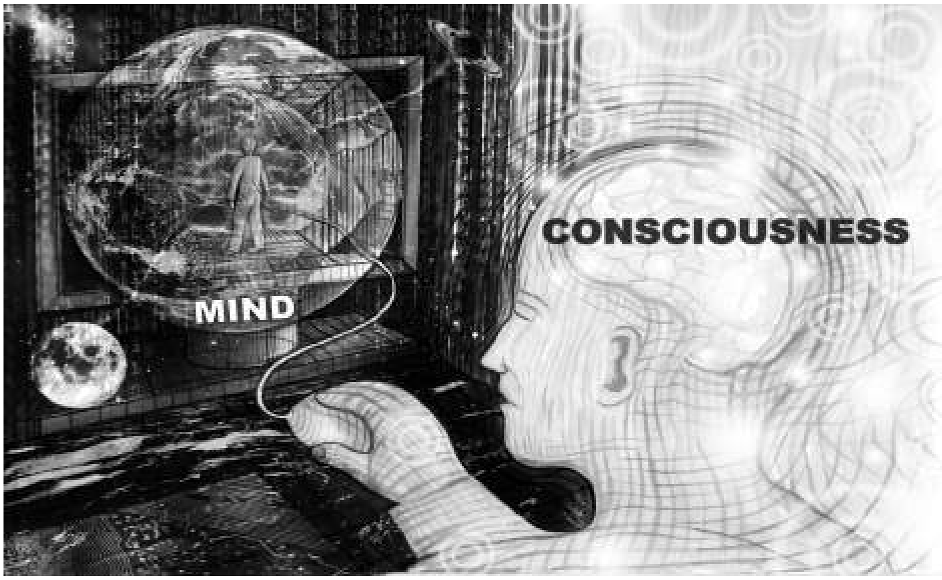

Figure 20: The mind 'virus' I have been writing about for decades seeks to isolate five-sense mind (the computer) from the true 'I'. (Image by Neil Hague).

About a year ago I came across a Native American concept of Wetiko which describes precisely the same phenomenon. Wetiko is the spelling used by the Cree and there are other versions including wintiko and windigo used by other tribal groups. They spell the name with lower case, but I see Wetiko as a proper noun as with Archons and prefer a capital. I first saw an article about Wetiko by writer and researcher Paul Levy which so synced with what I had been writing about the computer/operator disconnection and later the Archons. I then read his book, the fascinating *Dispelling Wetiko, Breaking the Spell of Evil*. The parallels between what I had concluded long before and the Native American concept of Wetiko were so clear and obvious that it was almost funny. For Wetiko see the Gnostic Archons for sure and the Jinn, the Predators, and every other name for a force of evil, inversion and chaos. Wetiko is the Native American name for the force that divides the computer from the operator (Fig 21). Indigenous author Jack D. Forbes, a founder of the Native American movement in the 1960s, wrote another book about Wetiko entitled *Columbus And Other Cannibals – The Wetiko Disease of Exploitation, Imperialism, and Terrorism* which I also read. Forbes says that Wetiko refers to an evil person or spirit 'who terrorizes other creatures by means of terrible acts, including cannibalism'. Zulu shaman Credo Mutwa told me that African accounts tell how cannibalism was brought into the world by the Chitauri 'gods' – another manifestation of Wetiko. The distinction between 'evil person or spirit' relates to Archons/Wetiko possessing a human or acting as pure consciousness. Wetiko is said to be a sickness of the soul or spirit and a state of being that takes but gives nothing back – the Cult and its operatives perfectly described. Black Hawk, a Native American war leader defending their lands from confiscation, said European invaders had 'poisoned hearts' – Wetiko hearts – and that this would spread to native societies. Mention of the heart is very significant as we shall shortly see. Forbes writes: 'Tragically, the history of the world for the past 2,000 years is, in great part, the story of the epidemiology of the wetiko disease.' Yes, and much longer. Forbes is correct when he says: 'The wetikos destroyed Egypt and Babylon and Athens and Rome and Tenochtitlan [capital of the Aztec empire] and perhaps now they will destroy the entire earth.' Evil, he said, is the number one export of a Wetiko culture – see its globalisation with 'Covid'. Constant war, mass murder, suffering of all kinds, child abuse, Satanism, torture and human sacrifice are all expressions of Wetiko and the Wetiko possessed. The world is Wetiko made manifest, *but it doesn't have to be*. There is a way out of this even now.

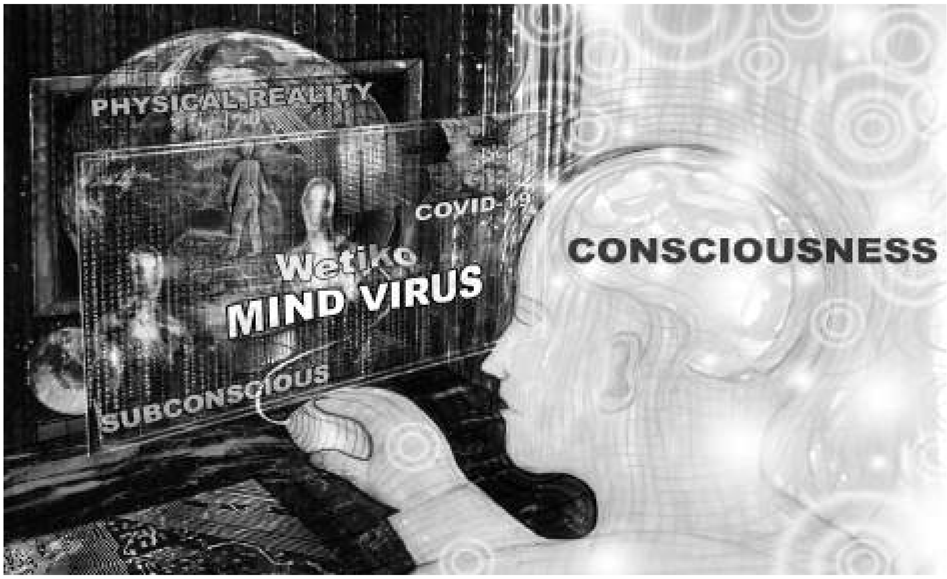

Figure 21: The mind 'virus' is known to Native Americans as 'Wetiko'. (Image by Neil Hague).

Cult of Wetiko

Wetiko is the Yaldabaoth frequency distortion that seeks to attach to human consciousness and absorb it into its own. Once this connection is made Wetiko can drive the perceptions of the target which they believe to be coming from their own mind. All the horrors of history and today from mass killers to Satanists, paedophiles like Jeffrey Epstein and other psychopaths, are the embodiment of Wetiko and express its state of being in all its grotesqueness. The Cult is Wetiko incarnate, Yaldabaoth incarnate, and it seeks to facilitate Wetiko assimilation of humanity in totality into its distortion by manipulating the population into low frequency states that match its own. Paul Levy writes: 'Holographically enforced within the psyche of every human being the wetiko virus pervades and underlies the entire field of consciousness, and can therefore potentially manifest through any one of us at any moment if we are not mindful.' The 'Covid' hoax has achieved this with many people, but others have not fallen into Wetiko's frequency lair. Players in the 'Covid' human catastrophe including Gates, Schwab, Tedros, Fauci, Whitty, Vallance, Johnson, Hancock, Ferguson, Drosten, and all the rest, including the psychopath psychologists, are expressions of Wetiko. This is why they have no compassion or empathy and no emotional consequence for what they do that would make them stop doing it. Observe all the people who support the psychopaths in authority against the Pushbackers despite the damaging impact the psychopaths have on their own lives and their family's lives. You are again looking at Wetiko possession which prevents them seeing through the lies to the obvious scam going on. *Why can't they see it?* Wetiko won't let them see it. The perceptual divide that has now become a chasm is between the Wetikoed and the non-Wetikoed.

Paul Levy describes Wetiko in the same way that I have long described the Archontic force. They are the same distorted consciousness operating across dimensions of reality: '… the subtle body of wetiko is not located in the third dimension of space and time, literally existing in another dimension … it is able to affect ordinary lives by mysteriously interpenetrating into our three-dimensional world.' Wetiko does this through its incarnate representatives in the Cult and by weaving itself into The Field which on our level of reality is the electromagnetic information field of the simulation or Matrix. More than that, the simulation *is* Wetiko / Yaldabaoth. Caleb Scharf, Director of Astrobiology at Columbia University, has speculated that 'alien life' could be so advanced that it has transcribed itself into the quantum realm to become what we call physics. He said intelligence indistinguishable from the fabric of the Universe would solve many of its greatest mysteries:

> Perhaps hyper-advanced life isn't just external. Perhaps it's already all around. It is embedded in what we perceive to be physics itself, from the root behaviour of particles and fields to the phenomena of complexity and emergence ... In other words, life might not just be in the equations. It might BE the equations [My emphasis].

Scharf said it is possible that 'we don't recognise advanced life because it forms an integral and unsuspicious part of what we've considered to be the natural world'. I agree. Wetiko/Yaldabaoth *is* the simulation. We are literally in the body of the beast. But that doesn't mean it has to control us. We all have the power to overcome Wetiko influence and the Cult knows that. I doubt it sleeps too well because it knows that.

Which Field?

This, I suggest, is how it all works. There are two Fields. One is the fierce electromagnetic light of the Matrix within the speed of light; the other is the 'watery light' of The Field beyond the walls of the Matrix that connects with the Great Infinity. Five-sense mind and the decoding systems of the body attach us to the Field of Matrix light. They have to or we could not experience this reality. Five-sense mind sees only the Matrix Field of information while our expanded consciousness is part of the Infinity Field. When we open our minds, and most importantly our hearts, to the Infinity Field we have a mission control which gives us an expanded perspective, a road map, to understand the nature of the five-sense world. If we are isolated only in five-sense mind there is no mission control. We're on our own trying to understand a world that's constantly feeding us information to ensure we do not understand. People in this state can feel 'lost' and bewildered with no direction or radar. You can see ever more clearly those who are influenced by the Fields of Big Infinity or little five-sense mind simply by their views and behaviour with regard to the 'Covid' hoax. We have had this division throughout known human history with the mass of the people on one side and individuals who could see and intuit beyond the walls of the simulation – Plato's prisoner who broke out of the cave and saw reality for what it is. Such people have always been targeted by Wetiko/Archon-possessed authority, burned at the stake or demonised as mad, bad and dangerous. The Cult today and its global network of 'anti-hate', 'anti-fascist' Woke groups are all expressions of Wetiko attacking those exposing the conspiracy, 'Covid' lies and the 'vaccine' agenda.

Woke as a whole is Wetiko which explains its black and white mentality and how at one it is with the Wetiko-possessed Cult. Paul Levy said: 'To be in this paradigm is to still be under the thrall of a two-valued logic – where things are either true or false – of a wetikoized mind.’ Wetiko consciousness is in a permanent rage, therefore so is Woke, and then there is Woke inversion and contradiction. ‘Anti-fascists’ act like fascists because fascists *and* ‘anti-fascists’ are both Wetiko at work. Political parties act the same while claiming to be different for the same reason. Secret society and satanic rituals are attaching initiates to Wetiko and the cold, ruthless, psychopathic mentality that secures the positions of power all over the world is Wetiko. Reframing ‘training programmes’ have the same cumulative effect of attaching Wetiko and we have their graduates described as automatons and robots with a cold, psychopathic, uncaring demeanour. They are all traits of Wetiko possession and look how many times they have been described in this book and elsewhere with regard to personnel behind ‘Covid’ including the police and medical profession. Climbing the greasy pole in any profession in a Wetiko society requires traits of Wetiko to get there and that is particularly true of politics which is not about fair competition and pre-eminence of ideas. It is founded on how many backs you can stab and arses you can lick. This culminated in the global ‘Covid’ coordination between the Wetiko possessed who pulled it off in all the different countries without a trace of empathy and compassion for their impact on humans. Our sight sense can see only holographic form and not the Field which connects holographic form. Therefore we perceive ‘physical’ objects with ‘space’ in between. In fact that ‘space’ is energy/consciousness operating on multiple frequencies. One of them is Wetiko and that connects the Cult psychopaths, those who submit to the psychopaths, and those who serve the psychopaths in the media operations of the world. Wetiko is Gates. Wetiko is the mask-wearing submissive. Wetiko is the fake journalist and ‘fact-checker’. The Wetiko Field is coordinating the whole thing. Psychopaths, gofers, media operatives, ‘anti-hate’ hate groups, ‘fact-checkers’ and submissive people work as one unit *even without human coordination* because they are attached to the *same* Field which is organising it all (Fig 22). Paul Levy is here describing how Wetiko-possessed people are drawn together and refuse to let any information breach their rigid perceptions. He was writing long before ‘Covid’, but I think you will recognise followers of the ‘Covid’ religion *oh just a little bit*:

> People who are channelling the vibratory frequency of wetiko align with each other through psychic resonance to reinforce their unspoken shared agreement so as to uphold their deranged view of reality. Once an unconscious content takes possession of certain individuals, it irresistibly draws them together by mutual attraction and knits them into groups tied together by their shared madness that can easily swell into an avalanche of insanity.
>
> A psychic epidemic is a closed system, which is to say that it is insular and not open to any new information or informing influences from the outside world which contradict its fixed, limited, and limiting perspective.

There we have the Woke mind and the ‘Covid’ mind. Compatible resonance draws the awakening together, too, which is clearly happening today.

Spiritual servitude

Wetiko doesn’t care about humans. It’s not human; it just possesses humans for its own ends and the effect (depending on the scale of possession) can be anything from extreme psychopathy to unquestioning obedience. Wetiko's worst nightmare is for human consciousness to expand beyond the simulation. Everything is focussed on stopping that happening through control of information, thus perception, thus frequency. The 'education system', media, science, medicine, academia, are all geared to maintaining humanity in five-sense servitude as is the constant stimulation of low-vibrational mental and emotional states (see 'Covid'). Wetiko seeks to dominate those subconscious spaces between five-sense perception and expanded consciousness where the computer meets the operator. From these subconscious hiding places Wetiko speaks to us to trigger urges and desires that we take to be our own and manipulate us into anything from low-vibrational to psychopathic states. Remember how Islam describes the Jinn as invisible tricksters that 'whisper' and confuse. Wetiko is the origin of the 'trickster god' theme that you find in cultures all over the world. Jinn, like the Archons, are Wetiko which is terrified of humans awakening and reconnecting with our true self for then its energy source has gone. With that the feedback loop breaks between Wetiko and human perception that provides the energetic momentum on which its very existence depends as a force of evil. Humans are both its target and its source of survival, but only if we are operating in low-vibrational states of fear, hate, depression and the background anxiety that most people suffer. We are Wetiko's target because we are its key to survival. It needs us, not the other way round. Paul Levy writes:

> A vampire has no intrinsic, independent, substantial existence in its own right; it only exists in relation to us. The pathogenic, vampiric mind-parasite called wetiko is nothing in itself – not being able to exist from its own side – yet it has a 'virtual reality' such that it can potentially destroy our species …
>
> …The fact that a vampire is not reflected by a mirror can also mean that what we need to see is that there's nothing, no-thing to see, other than ourselves. The fact that wetiko is the expression of something inside of us means that the cure for wetiko is with us as well. The critical issue is finding this cure within us and then putting it into effect.

Evil begets evil because if evil does not constantly expand and find new sources of energetic sustenance its evil, its *distortion*, dies with the assimilation into balance and harmony. Love is the garlic to Wetiko's vampire. Evil, the absence of love, cannot exist in the presence of love. I think I see a way out of here. I have emphasised so many times over the decades that the Archons/Wetiko and their Cult are not all powerful. *They are not*. I don't care how it looks even now *they are not*. I have not called them little boys in short trousers for effect. I have said it because it is true. Wetiko's insatiable desire for power over others is not a sign of its omnipotence, but its insecurity. Paul Levy writes: 'Due to the primal fear which ultimately drives it and which it is driven to cultivate, wetiko's body politic has an intrinsic and insistent need for centralising power and control so as to create imagined safety for itself.' *Yeeeeeees!* Exactly! Why does Wetiko want humans in an ongoing state of fear? Wetiko itself *is* fear and it is petrified of love. As evil is an absence of love, so love is an absence of fear. Love conquers all and *especially* Wetiko which *is* fear. Wetiko brought fear into the world when it wasn't here before. *Fear* was the 'fall', the fall into low-frequency ignorance and illusion – fear is **F**alse **E**motion **A**ppearing **R**eal. The simulation is driven and energised by fear because Wetiko/Yaldabaoth (fear) *are* the simulation. Fear is the absence of love and Wetiko is the absence of love.

Wetiko today

We can now view current events from this level of perspective. The 'Covid' hoax has generated momentous amounts of ongoing fear, anxiety, depression and despair which have empowered Wetiko. No wonder people like Gates have been the instigators when they are Wetiko incarnate and exhibit every trait of Wetiko in the extreme. See how cold and unemotional these people are like Gates and his cronies, how dead of eye they are. That's Wetiko. Sabbatians are Wetiko and everything they control including the World Health Organization, Big Pharma and the 'vaccine' makers, national 'health' hierarchies, corporate media, Silicon Valley, the banking system, and the United Nations with its planned transformation into world government. All are controlled and possessed by the Wetiko distortion into distorting human society in its image. We are with this knowledge at the gateway to understanding the world. Divisions of race, culture, creed and sexuality are diversions to hide the real division between those possessed and influenced by Wetiko and those that are not. The 'Covid' hoax has brought both clearly into view. Human behaviour is not about race. Tyrants and dictatorships come in all colours and creeds. What unites the US president bombing the innocent and an African tribe committing genocide against another as in Rwanda? What unites them? *Wetiko*. All wars are Wetiko, all genocide is Wetiko, all hunger over centuries in a world of plenty is Wetiko. Children going to bed hungry, including in the West, is Wetiko. Cult-generated Woke racial divisions that focus on the body are designed to obscure the reality that divisions in behaviour are manifestations of mind, not body. Obsession with body identity and group judgement is a means to divert attention from the real source of behaviour – mind and perception. Conflict sown by the Woke both within themselves and with their target groups are Wetiko providing lunch for itself through still more agents of the division, chaos, and fear on which it feeds. The Cult is seeking to assimilate the entirety of humanity and all children and young people into the Wetiko frequency by manipulating them into states of fear and despair. Witness all the suicide and psychological unravelling since the spring of 2020. Wetiko psychopaths want to impose a state of unquestioning obedience to authority which is no more than a conduit for Wetiko to enforce its will and assimilate humanity into itself. It needs us to believe that resistance is futile when it fears resistance and even more so the game-changing non-cooperation with its impositions. It can use violent resistance for its benefit. Violent impositions and violent resistance are *both* Wetiko. The Power of Love with its Power of No will sweep Wetiko from our world. Wetiko and its Cult know that. They just don't want us to know.

AI Wetiko

This brings me to AI or artificial intelligence and something else Wetikos don't want us to know. What is AI *really*? I know about computer code algorithms and AI that learns from data input. These, however, are more diversions, the expeditionary force, for the real AI that they want to connect to the human brain as promoted by Silicon Valley Wetikos like Kurzweil. What is this AI? It is the frequency of *Wetiko*, the frequency of the Archons. The connection of AI to the human brain is the connection of the Wetiko frequency to create a Wetiko hive mind and complete the job of assimilation. The hive mind is planned to be controlled from Israel and China which are both 100 percent owned by Wetiko Sabbatians. The assimilation process has been going on minute by minute in the 'smart' era which fused with the 'Covid' era. We are told that social media is scrambling the minds of the young and changing their personality. This is true, but what is social media? Look more deeply at how it works, how it creates divisions and conflict, the hostility and cruelty, the targeting of people until they are destroyed. That's Wetiko. Social media is manipulated to tune people to the Wetiko frequency with all the emotional exploitation tricks employed by platforms like Facebook and its Wetiko front man, Zuckerberg. Facebook's Instagram announced a new platform for children to overcome a legal bar on them using the main site. This is more Wetiko exploitation and manipulation of kids. Amnesty International likened the plan to foxes offering to guard the henhouse and said it was incompatible with human rights. Since when did Wetiko or Zuckerberg (I repeat myself) care about that? Would Brin and Page at Google, Wojcicki at YouTube, Bezos at Amazon and whoever the hell runs Twitter act as they do if they were not channelling Wetiko? Would those who are developing technologies for no other reason than human control? How about those designing and selling technologies to kill people and Big Pharma drug and 'vaccine' producers who know they will end or devastate lives? Quite a thought for these people to consider is that if you are Wetiko in a human life you are Wetiko on the 'other side' unless your frequency changes and that can only change by a change of perception which becomes a change of behaviour. Where Gates is going does not bear thinking about although perhaps that's exactly where he wants to go. Either way, that's where he's going. His frequency will make it so.

The frequency lair

I have been saying for a long time that a big part of the addiction to smartphones and devices is that a frequency is coming off them that entraps the mind. People spend ages on their phones and sometimes even a minute or so after they put them down they pick them up again and it all repeats. 'Covid' lockdowns will have increased this addiction a million times for obvious reasons. Addictions to alcohol overindulgence and drugs are another way that Wetiko entraps consciousness to attach to its own. Both are symptoms of low-vibrational psychological distress which alcoholism and drug addiction further compound. Do we think it's really a coincidence that access to them is made so easy while potions that can take people into realms beyond the simulation are banned and illegal? I have explored smartphone addiction in other books, the scale is mind-blowing, and that level of addiction does not come without help. Tech companies that make these phones are Wetiko and they will have no qualms about destroying the minds of children. We are seeing again with these companies the Wetiko perceptual combination of psychopathic enforcers and weak and meek unquestioning compliance by the rank and file.

The global Smart Grid is the Wetiko Grid and it is crucial to complete the Cult endgame. The simulation is radiation and we are being deluged with technological radiation on a devastating scale. Wetiko frauds like Elon Musk serve Cult interests while occasionally criticising them to maintain his street-cred. 5G and other forms of Wi-Fi are being directed at the earth from space on a volume and scale that goes on increasing by the day. Elon Musk's (officially) SpaceX Starlink project is in the process of putting tens of thousands of satellites in low orbit to cover every inch of the planet with 5G and other Wi-Fi to create Kurzweil's global 'cloud' to which the human mind is planned to be attached very soon. SpaceX has approval to operate 12,000 satellites with more than 1,300 launched at the time of writing and applications filed for *30,000* more. Other operators in the Wi-Fi, 5G, low-orbit satellite market include OneWeb (UK), Telesat (Canada), and AST & Science (US). Musk tells us that AI could be the end of humanity and then launches a company called Neuralink to connect the human brain to computers. Musk's (in theory) Tesla company is building electric cars and the driverless vehicles of the smart control grid. As frauds and bullshitters go Elon Musk in my opinion is Major League.

5G and technological radiation in general are destructive to human health, genetics and psychology and increasing the strength of artificial radiation underpins the five-sense perceptual bubbles which are themselves expressions of radiation or electromagnetism. Freedom activist John Whitehead was so right with his 'databit by databit, we are building our own electronic concentration camps'. The Smart Grid and 5G is a means to control the human mind and infuse perceptual information into The Field to influence anyone in sync with its frequency. You can change perception and behaviour en masse if you can manipulate the population into those levels of frequency and this is happening all around us today. The arrogance of Musk and his fellow Cult operatives knows no bounds in the way that we see with Gates. Musk's satellites are so many in number already they are changing the night sky when viewed from Earth. The astronomy community has complained about this and they have seen nothing yet. Some consequences of Musk's Wetiko hubris include: Radiation; visible pollution of the night sky; interference with astronomy and meteorology; ground and water pollution from intensive use of increasingly many spaceports; accumulating space debris; continual deorbiting and burning up of aging satellites, polluting the atmosphere with toxic dust and smoke; and ever-increasing likelihood of collisions. A collective public open letter of complaint to Musk said:

> We are writing to you … because SpaceX is in process of surrounding the Earth with a network of thousands of satellites whose very purpose is to irradiate every square inch of the

> Earth. SpaceX, like everyone else, is treating the radiation as if it were not there. As if the mitochondria in our cells do not depend on electrons moving undisturbed from the food we digest to the oxygen we breathe.
>
> As if our nervous systems and our hearts are not subject to radio frequency interference like any piece of electronic equipment. As if the cancer, diabetes, and heart disease that now afflict a majority of the Earth's population are not metabolic diseases that result from interference with our cellular machinery. As if insects everywhere, and the birds and animals that eat them, are not starving to death as a result.

People like Musk and Gates believe in their limitless Wetiko arrogance that they can do whatever they like to the world because they own it. Consequences for humanity are irrelevant. It's absolutely time that we stopped taking this shit from these self-styled masters of the Earth when you consider where this is going.

Why is the Cult so anti-human?

I hear this question often: Why would they do this when it will affect them, too? Ah, but will it? Who is this *them*? Forget their bodies. They are just vehicles for Wetiko consciousness. When you break it all down to the foundations we are looking at a state of severely distorted consciousness targeting another state of consciousness for assimilation. The rest is detail. The simulation is the fly-trap in which unique sensations of the five senses create a cycle of addiction called reincarnation. Renegade Minds see that everything which happens in our reality is a smaller version of the whole picture in line with the holographic principle. Addiction to the radiation of smart technology is a smaller version of addiction to the whole simulation. Connecting the body/brain to AI is taking that addiction on a giant step further to total ongoing control by assimilating human incarnate consciousness into Wetiko. I have watched during the 'Covid' hoax how many are becoming ever more profoundly attached to Wetiko's perceptual calling cards of aggressive response to any other point of view ('There is no other god but me'), psychopathic lack of compassion and empathy, and servile submission to the narrative and will of authority. Wetiko is the psychopaths *and* subservience to psychopaths. The Cult of Wetiko is so anti-human because it is *not* human. It embarked on a mission to destroy human by targeting everything that it means to be human and to survive as human. 'Covid' is not the end, just a means to an end. The Cult with its Wetiko consciousness is seeking to change Earth systems, including the atmosphere, to suit them, not humans. The gathering bombardment of 5G alone from ground and space is dramatically changing The Field with which the five senses interact. There is so much more to come if we sit on our hands and hope it will all go away. It is not meant to go away. It is meant to get ever more extreme and we need to face that while we still can – just.

Carbon dioxide is the gas of life. Without that human is over. Kaput, gone, history. No natural world, no human. The Cult has created a cock and bull story about carbon dioxide and climate change to justify its reduction to the point where Gates and the ignoramus Biden 'climate chief' John Kerry want to suck it out of the atmosphere. Kerry wants to do this because his master Gates does. Wetikos have made the gas of life a demon with the usual support from the Wokers of Extinction Rebellion and similar organisations and the bewildered puppet-child that is Greta Thunberg who was put on the world stage by Klaus Schwab and the World Economic Forum. The name Extinction Rebellion is both ironic and as always Wetiko inversion. The gas that we need to survive must be reduced to save us from extinction. The most basic need of human is oxygen and we now have billions walking around in face nappies depriving body and brain of this essential requirement of human existence. More than that 5G at 60 gigahertz interacts with the oxygen molecule to reduce the amount of oxygen the body can absorb into the bloodstream. The obvious knock-on consequences of that for respiratory and cognitive problems and life itself need no further explanation. Psychopaths like Musk are assembling a global system of satellites to deluge the human atmosphere with this insanity. The man should be in jail. Here we have two most basic of human needs, oxygen and carbon dioxide, being dismantled.

Two others, water and food, are getting similar treatment with the United Nations Agendas 21 and 2030 – the Great Reset – planning to centrally control all water and food supplies. People will not even own rain water that falls on their land. Food is affected at the most basic level by reducing carbon dioxide. We have genetic modification or GMO infiltrating the food chain on a mass scale, pesticides and herbicides polluting the air and destroying the soil. Freshwater fish that provide livelihoods for 60 million people and feed hundreds of millions worldwide are being 'pushed to the brink' according the conservationists while climate change is the only focus. Now we have Gates and Schwab wanting to dispense with current food sources all together and replace them with a synthetic version which the Wetiko Cult would control in terms of production and who eats and who doesn't. We have been on the Totalitarian Tiptoe to this for more than 60 years as food has become ever more processed and full of chemical shite to the point today when it's not natural food at all. As Dr Tom Cowan says: 'If it has a label don't eat it.' Bill Gates is now the biggest owner of farmland in the United States and he does nothing without an ulterior motive involving the Cult. Klaus Schwab wrote: 'To feed the world in the next 50 years we will need to produce as much food as was produced in the last 10,000 years … food security will only be achieved, however, if regulations on genetically modified foods are adapted to reflect the reality that gene editing offers a precise, efficient and safe method of improving crops.' Liar. People and the world are being targeted with aluminium through vaccines, chemtrails, food, drink cans, and endless other sources when aluminium has been linked to many health issues including dementia which is increasing year after year. Insects, bees and wildlife essential to the food chain are being deleted by pesticides, herbicides and radiation which 5G is dramatically increasing with 6G and 7G to come. The pollinating bee population is being devastated while wildlife including birds, dolphins and whales are having their natural radar blocked by the effects of ever-increasing radiation. In the summer windscreens used to be splattered with insects so numerous were they. It doesn't happen now. Where have they gone?

Synthetic everything

The Cult is introducing genetically-modified versions of trees, plants and insects including a Gates-funded project to unleash hundreds of millions of genetically-modified, lab-altered and patented male mosquitoes to mate with wild mosquitoes and induce genetic flaws that cause them to die out. Clinically-insane Gates-funded Japanese researchers have developed mosquitos that spread vaccine and are dubbed 'flying vaccinators'. Gates is funding the modification of weather patterns in part to sell the myth that this is caused by carbon dioxide and he's funding geoengineering of the skies to change the atmosphere. Some of this came to light with the Gates-backed plan to release tonnes of chalk into the atmosphere to 'deflect the Sun and cool the planet'. Funny how they do this while the heating effect of the Sun is not factored into climate projections focussed on carbon dioxide. The reason is that they want to reduce carbon dioxide (so don't mention the Sun), but at the same time they do want to reduce the impact of the Sun which is so essential to human life and health. I have mentioned the sun-cholesterol-vitamin D connection as they demonise the Sun with warnings about skin cancer (caused by the chemicals in sun cream they tell you to splash on). They come from the other end of the process with statin drugs to reduce cholesterol that turns sunlight into vitamin D. A lack of vitamin D leads to a long list of health effects and how vitamin D levels must have fallen with people confined to their homes over 'Covid'. Gates is funding other forms of geoengineering and most importantly chemtrails which are dropping heavy metals, aluminium and self-replicating nanotechnology onto the Earth which is killing the natural world. See *Everything You Need To Know, But Have Never Been Told* for the detailed background to this.

Every human system is being targeted for deletion by a force that's not human. The Wetiko Cult has embarked on the process of transforming the human body from biological to synthetic biological as I have explained. Biological is being replaced by the artificial and synthetic – Archontic 'countermimicry' – right across human society. The plan eventually is to dispense with the human body altogether and absorb human consciousness – which it wouldn't really be by then – into cyberspace (the simulation which is Wetiko/Yaldabaoth). Preparations for that are already happening if people would care to look. The alternative media rightly warns about globalism and 'the globalists', but this is far bigger than that and represents the end of the human race as we know it. The 'bad copy' of prime reality that Gnostics describe was a bad copy of harmony, wonder and beauty to start with before Wetiko/Yaldabaoth set out to change the simulated 'copy' into something very different. The process was slow to start with. Entrapped humans in the simulation timeline were not technologically aware and they had to be brought up to intellectual speed while being suppressed spiritually to the point where they could build their own prison while having no idea they were doing so. We have now reached that stage where technological intellect has the potential to destroy us and that's why events are moving so fast. Central American shaman Don Juan Matus said:

> Think for a moment, and tell me how you would explain the contradictions between the intelligence of man the engineer and the stupidity of his systems of belief, or the stupidity of his contradictory behaviour. Sorcerers believe that the predators have given us our systems of beliefs, our ideas of good and evil; our social mores. They are the ones who set up our dreams of success or failure. They have given us covetousness, greed, and cowardice. It is the predator who makes us complacent, routinary, and egomaniacal.
>
> In order to keep us obedient and meek and weak, the predators engaged themselves in a stupendous manoeuvre – stupendous, of course, from the point of view of a fighting strategist; a horrendous manoeuvre from the point of those who suffer it. They gave us their mind. The predators' mind is baroque, contradictory, morose, filled with the fear of being discovered any minute now.

For 'predators' see Wetiko, Archons, Yaldabaoth, Jinn, and all the other versions of the same phenomenon in cultures and religions all over the world. The theme is always the same because it's true and it's real. We have reached the point where we have to deal with it. The question is – how?

Don't fight – walk away

I thought I'd use a controversial subheading to get things moving in terms of our response to global fascism. What do you mean 'don't fight'? What do you mean 'walk away'? We've got to fight. We can't walk away. Well, it depends what we mean by fight and walk away. If fighting means physical combat we are playing Wetiko's game and falling for its trap. It wants us to get angry, aggressive, and direct hate and hostility at the enemy we think we must fight. Every war, every battle, every conflict, has been fought with Wetiko leading both sides. It's what it does. Wetiko wants a fight, anywhere, any place. Just hit me, son, so I can hit you back. Wetiko hits Wetiko and Wetiko hits Wetiko in return. I am very forthright as you can see in exposing Wetikos of the Cult, but I don't hate them. I refuse to hate them. It's what they want. What you hate you become. What you *fight* you become. Wokers, 'anti-haters' and 'anti-fascists' prove this every time they reach for their keyboards or don their balaclavas. By walk away I mean to disengage from Wetiko which includes ceasing to cooperate with its tyranny. Paul Levy says of Wetiko:

> The way to 'defeat' evil is not to try to destroy it (for then, in playing evil's game, we have already lost), but rather, to find the invulnerable place within ourselves where evil is unable to vanquish us – this is to truly 'win' our battle with evil.

Wetiko is everywhere in human society and it's been on steroids since the 'Covid' hoax. Every shouting match over wearing masks has Wetiko wearing a mask and Wetiko not wearing one. It's an electrical circuit of push and resist, push and resist, with Wetiko pushing *and* resisting. Each polarity is Wetiko empowering itself. Dictionary definitions of 'resist' include 'opposing, refusing to accept or comply with' and the word to focus on is 'opposing'. What form does this take – setting police cars alight or 'refusing to accept or comply with'? The former is Wetiko opposing Wetiko while the other points the way forward. This is the difference between those aggressively demanding that government fascism must be obeyed who stand in stark contrast to the great majority of Pushbackers. We saw this clearly with a march by thousands of Pushbackers against lockdown in London followed days later by a Woker-hijacked protest in Bristol in which police cars were set on fire. Masks were virtually absent in London and widespread in Bristol. Wetiko wants lockdown on every level of society and infuses its aggression to police it through its unknowing stooges. Lockdown protesters are the ones with the smiling faces and the hugs, The two blatantly obvious states of being – getting more obvious by the day – are the result of Wokers and their like becoming ever more influenced by the simulation Field of Wetiko and Pushbackers ever more influenced by The Field of a far higher vibration beyond the simulation. Wetiko can't invade the heart which is where most lockdown opponents are coming from. It's the heart that allows them to see through the lies to the truth in ways I will be highlighting.

Renegade Minds know that calmness is the place from which wisdom comes. You won't find wisdom in a hissing fit and wisdom is what we need in abundance right now. Calmness is not weakness – you don't have to scream at the top of your voice to be strong. Calmness is indeed a sign of strength. 'No' means I'm not doing it. *NOOOO!!!* doesn't mean you're not doing it even more. Volume does not advance 'No – I'm not doing it'. You are just not doing it. Wetiko possessed and influenced don't know how to deal with that. Wetiko wants a fight and we should not give it one. What it needs more than anything is our *cooperation* and we should not give that either. Mass rallies and marches are great in that they are a visual representation of feeling, but if it ends there they are irrelevant. You demand that Wetikos act differently? Well, they're not going to are they? They are Wetikos. We don't need to waste our time demanding that something doesn't happen when that will make no difference. We need to delete the means that *allows* it to happen. This, invariably, is our cooperation. You can demand a child stop firing a peashooter at the dog or you can refuse to buy the peashooter. If you provide the means you are cooperating with the dog being smacked on the nose with a pea. How can the authorities enforce mask-wearing if millions in a country refuse? What if the 74 million Pushbackers that voted for Trump in 2020 refused to wear masks, close their businesses or stay in their homes. It would be unenforceable. The few control the many through the compliance of the many and that's always been the dynamic be it 'Covid' regulations or the Roman Empire. I know people can find it intimidating to say no to authority or stand out in a crowd for being the only one with a face on display; but it has to be done or it's over. I hope I've made clear in this book that where this is going will be far more intimidating than standing up now and saying 'No' – I will not cooperate with my own enslavement and that of my children. There might be consequences for some initially, although not so if enough do the same. The question that must be addressed is what is going to happen if we don't? It is time to be strong and unyieldingly so. No means no. Not here and there, but *everywhere* and *always*. I have refused to wear a mask and obey all the other nonsense. I will not comply with tyranny. I repeat: Fascism is not imposed by fascists – there are never enough of them. Fascism is imposed by the population acquiescing to fascism. *I will not do it*. I will die first, or my body will. Living meekly under fascism is a form of death anyway, the death of the spirit that Martin Luther King described.

Making things happen

We must not despair. This is not over till it's over and it's far from that. The 'fat lady' must refuse to sing. The longer the 'Covid' hoax has dragged on and impacted on more lives we have seen an awakening of phenomenal numbers of people worldwide to the realisation that what they have believed all their lives is not how the world really is. Research published by the system-serving University of Bristol and King's College London in February, 2021, concluded: 'One in every 11 people in Britain say they trust David Icke's take on the coronavirus pandemic.' It will be more by now and we have gathering numbers to build on. We must urgently progress from seeing the scam to ceasing to cooperate with it. Prominent German lawyer Reiner Fuellmich, also licenced to practice law in America, is doing a magnificent job taking the legal route to bring the psychopaths to justice through a second Nuremberg tribunal for crimes against humanity. Fuellmich has an impressive record of beating the elite in court and he formed the German Corona Investigative Committee to pursue civil charges against the main perpetrators with a view to triggering criminal charges. Most importantly he has grasped the foundation of the hoax – the PCR test not testing for the 'virus' – and Christian Drosten is therefore on his charge sheet along with Gates frontman Tedros at the World Health Organization. Major players must be not be allowed to inflict their horrors on the human race without being brought to book. A life sentence must follow for Bill Gates and the rest of them. A group of researchers has also indicted the government of Norway for crimes against humanity with copies sent to the police and the International Criminal Court. The lawsuit cites participation in an internationally-planned false pandemic and violation of international law and human rights, the European Commission's definition of human rights by coercive rules, Nuremberg and Hague rules on fundamental human rights, and the Norwegian constitution. We must take the initiative from hereon and not just complain, protest and react.

There are practical ways to support vital mass non-cooperation. Organising in numbers is one. Lockdown marches in London in the spring in 2021 were mass non-cooperation that the authorities could not stop. There were too many people. Hundreds of thousands walked the London streets in the centre of the road for mile after mile while the Face-Nappies could only look on. They were determined, but calm, and just *did it* with no histrionics and lots of smiles. The police were impotent. Others are organising group shopping without masks for mutual support and imagine if that was happening all over. Policing it would be impossible. If the store refuses to serve people in these circumstances they would be faced with a long line of trolleys full of goods standing on their own and everything would have to be returned to the shelves. How would they cope with that if it kept happening? I am talking here about moving on from complaining to being pro-active; from watching things happen to making things happen. I include in this our relationship with the police. The behaviour of many Face-Nappies has been disgraceful and anyone who thinks they would never find concentration camp guards in the 'enlightened' modern era have had that myth busted big-time. The period and setting may change – Wetikos never do. I watched film footage from a London march in which a police thug viciously kicked a protestor on the floor who had done nothing. His fellow Face-Nappies stood in a ring protecting him. What he did was a criminal assault and with a crowd far outnumbering the police this can no longer be allowed to happen unchallenged. I get it when people chant 'shame on you' in these circumstances, but that is no longer enough. They *have* no shame those who do this. Crowds needs to start making a citizen's arrest of the police who commit criminal offences and brutally attack innocent people and defenceless women. A citizen's arrest can be made under section 24A of the UK Police and Criminal Evidence (PACE) Act of 1984 and you will find something similar in other countries. I prefer to call it a Common Law arrest rather than citizen's for reasons I will come to shortly. Anyone can arrest a person committing an indictable offence or if they have reasonable grounds to suspect they are committing an indictable offence. On both counts the attack by the police thug would have fallen into this category. A citizen's arrest can be made to stop someone:

- Causing physical injury to himself or any other person
- Suffering physical injury
- Causing loss of or damage to property
- Making off before a constable can assume responsibility for him

A citizen's arrest may also be made to prevent a breach of the peace under Common Law and if they believe a breach of the peace will happen or anything related to harm likely to be done or already done in their presence. This is the way to go I think – the Common Law version. If police know that the crowd and members of the public will no longer be standing and watching while they commit their thuggery and crimes they will think twice about acting like Brownshirts and Blackshirts.

Common Law – common sense

Mention of Common Law is very important. Most people think the law is the law as in one law. This is not the case. There are two bodies of law, Common Law and Statute Law, and they are not the same. Common Law is founded on the simple premise of do no harm. It does not recognise victimless crimes in which no harm is done while Statute Law does. There is a Statute Law against almost everything. So what is Statute Law? Amazingly it's the law of the *sea* that was brought ashore by the Cult to override the law of the land which is Common Law. They had no right to do this and as always they did it anyway. They had to. They could not impose their will on the people through Common Law which only applies to do no harm. How could you stitch up the fine detail of people's lives with that? Instead they took the law of the sea, or Admiralty Law, and applied it to the population. Statute Law refers to all the laws spewing out of governments and their agencies including all the fascist laws and regulations relating to 'Covid'. The key point to make is that Statute Law is *contract law*. It only applies between *contracting* corporations. Most police officers don't even know this. They have to be kept in the dark, too. Long ago when merchants and their sailing ships began to trade with different countries a contractual law was developed called Admiralty Law and other names. Again it only applied to *contracts* agreed between *corporate* entities. If there is no agreed contract the law of the sea had no jurisdiction *and that still applies to its new alias of Statute Law*. The problem for the Cult when the law of the sea was brought ashore was an obvious one. People were not corporations and neither were government entities. To overcome the latter they made governments and all associated organisations corporations. All the institutions are *private corporations* and I mean governments and their agencies, local councils, police, courts, military, US states, the whole lot. Go to the

Dun and Bradstreet corporate listings website for confirmation that they are all corporations. You are arrested by a private corporation called the police by someone who is really a private security guard and they take you to court which is another private corporation. Neither have jurisdiction over you unless you consent and *contract* with them. This is why you hear the mantra about law enforcement policing by *consent* of the people. In truth the people 'consent' only in theory through monumental trickery.

Okay, the Cult overcame the corporate law problem by making governments and institutions corporate entities; but what about people? They are not corporations are they? Ah ... well in a sense, and *only* a sense, they are. Not people exactly – the illusion of people. The Cult creates a corporation in the name of everyone at the time that their birth certificate is issued. Note birth/ *berth* certificate and when you go to court under the law of the sea on land you stand in a *dock*. These are throwbacks to the origin. My Common Law name is David Vaughan Icke. The name of the corporation created by the government when I was born is called Mr David Vaughan Icke usually written in capitals as MR DAVID VAUGHAN ICKE. That is not me, the living, breathing man. It is a fictitious corporate entity. The trick is to make you think that David Vaughan Icke and MR DAVID VAUGHAN ICKE are the same thing. *They are not*. When police charge you and take you to court they are prosecuting the corporate entity and not the living, breathing, man or woman. They have to trick you into identifying as the corporate entity and contracting with them. Otherwise they have no jurisdiction. They do this through a language known as legalese. Lawful and legal are not the same either. Lawful relates to Common Law and legal relates to Statute Law. Legalese is the language of Statue Law which uses terms that mean one thing to the public and another in legalese. Notice that when a police officer tells someone why they are being charged he or she will say at the end: 'Do you understand?' To the public that means 'Do you comprehend?' In legalese it means 'Do you stand under me?' Do you stand under my authority? If you say yes to the question you are unknowingly agreeing to give them jurisdiction over you in a contract between two corporate entities.

This is a confidence trick in every way. Contracts have to be agreed between informed parties and if you don't know that David Vaughan Icke is agreeing to be the corporation MR DAVID VAUGHAN ICKE you cannot knowingly agree to contract. They are deceiving you and another way they do this is to ask for proof of identity. You usually show them a driving licence or other document on which your corporate name is written. In doing so you are accepting that you are that corporate entity when you are not. Referring to yourself as a 'person' or 'citizen' is also identifying with your corporate fiction which is why I made the Common Law point about the citizen's arrest. If you are approached by a police officer you identify yourself immediately as a living, breathing, man or woman and say 'I do not consent, I do not contract with you and I do not understand' or stand under their authority. I have a Common Law birth certificate as a living man and these are available at no charge from commonlawcourt.com. Businesses registered under the Statute Law system means that its laws apply. There are, however, ways to run a business under Common Law. Remember all 'Covid' laws and regulations are Statute Law – the law of *contracts* and you do not have to contract. This doesn't mean that you can kill someone and get away with it. Common Law says do no harm and that applies to physical harm, financial harm etc. Police are employees of private corporations and there needs to be a new system of non-corporate Common Law constables operating outside the Statute Law system. If you go to davidicke.com and put Common Law into the search engine you will find videos that explain Common Law in much greater detail. It is definitely a road we should walk.

With all my heart

I have heard people say that we are in a spiritual war. I don't like the term 'war' with its Wetiko dynamic, but I know what they mean. Sweep aside all the bodily forms and we are in a situation in which two states of consciousness are seeking very different realities.

Wetiko wants upheaval, chaos, fear, suffering, conflict and control. The other wants love, peace, harmony, fairness and freedom. That's where we are. We should not fall for the idea that Wetiko is all-powerful and there's nothing we can do. Wetiko is not all-powerful. It's a joke, pathetic. It doesn't have to be, but it has made that choice for now. A handful of times over the years when I have felt the presence of its frequency I have allowed it to attach briefly so I could consciously observe its nature. The experience is not pleasant, the energy is heavy and dark, but the ease with which you can kick it back out the door shows that its real power is in persuading us that it has power. It's all a con. Wetiko is a con. It's a trickster and not a power that can control us if we unleash our own. The con is founded on manipulating humanity to give its power to Wetiko which recycles it back to present the illusion that it has power when its power is *ours* that we gave away. This happens on an energetic level and plays out in the world of the seen as humanity giving its power to Wetiko authority which uses that power to control the population when the power is only the power the population has handed over. How could it be any other way for billions to be controlled by a relative few? I have had experiences with people possessed by Wetiko and again you can kick its arse if you do it with an open heart. Oh yes – the *heart* which can transform the world of perceived 'matter'.

We are receiver-transmitters and processors of information, but what information and where from? Information is processed into perception in three main areas – the brain, the heart and the belly. These relate to thinking, knowing, and emotion. Wetiko wants us to be head and belly people which means we think within the confines of the Matrix simulation and low-vibrational emotional reaction scrambles balance and perception. A few minutes on social media and you see how emotion is the dominant force. Woke is all emotion and is therefore thought-free and fact-free. Our heart is something different. It *knows* while the head *thinks* and has to try to work it out because it doesn't know. The human energy field has seven prime vortexes which connect us with wider reality (Fig 23). Chakra means ‘wheels of light’ in the Sanskrit language of ancient India. The main ones are: The crown chakra on top of the head; brow (or ‘third eye’) chakra in the centre of the forehead; throat chakra; heart chakra in the centre of the chest; solar plexus chakra below the sternum; sacral chakra beneath the navel; and base chakra at the bottom of the spine. Each one has a particular function or functions. We feel anxiety and nervousness in the belly where the sacral chakra is located and this processes emotion that can affect the colon to give people ‘the shits’ or make them ‘shit scared’ when they are nervous. Chakras all play an important role, but the Mr and Mrs Big is the heart chakra which sits at the centre of the seven, above the chakras that connect us to the ‘physical’ and below those that connect with higher realms (or at least should). Here in the heart chakra we feel love, empathy and compassion – ‘My heart goes out to you’. Those with closed hearts become literally ‘heart-less’ in their attitudes and behaviour (see Bill Gates). Native Americans portrayed Wetiko with what Paul Levy calls a ‘frigid, icy heart, devoid of mercy’ (see Bill Gates).

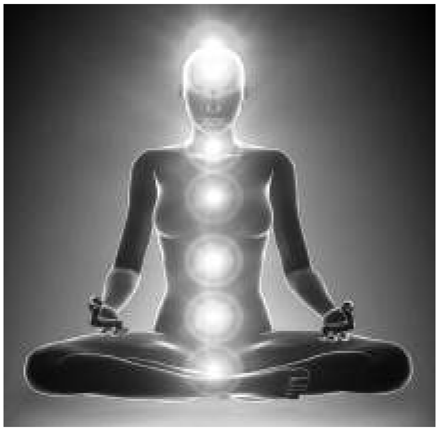

Figure 23: The chakra system which interpenetrates the human energy field. The heart chakra is the governor – or should be.

Wetiko trembles at the thought of heart energy which it cannot infiltrate. The frequency is too high. What it seeks to do instead is close the heart chakra vortex to block its perceptual and energetic influence. Psychopaths have ‘hearts of stone’ and emotionally-damaged people have ‘heartache’ and ‘broken hearts’. The astonishing amount of heart disease is related to heart chakra disruption with its fundamental connection to the 'physical' heart. Dr Tom Cowan has written an outstanding book challenging the belief that the heart is a pump and making the connection between the 'physical' and spiritual heart. Rudolph Steiner who was way ahead of his time said the same about the fallacy that the heart is a pump. *What*? The heart is not a pump? That's crazy, right? Everybody knows that. Read Cowan's *Human Heart, Cosmic Heart* and you will realise that the very idea of the heart as a pump is ridiculous when you see the evidence. How does blood in the feet so far from the heart get pumped horizontally up the body by the heart?? Cowan explains in the book the real reason why blood moves as it does. Our 'physical' heart is used to symbolise love when the source is really the heart vortex or spiritual heart which is our most powerful energetic connection to 'out there' expanded consciousness. That's why we feel *knowing* – intuitive knowing – in the centre of the chest. Knowing doesn't come from a process of thoughts leading to a conclusion. It is there in an instant all in one go. Our heart knows because of its connection to levels of awareness that *do* know. This is the meaning and source of intuition – intuitive *knowing*.

For the last more than 30 years of uncovering the global game and the nature of reality my heart has been my constant antenna for truth and accuracy. An American intelligence insider once said that I had quoted a disinformer in one of my books and yet I had only quoted the part that was true. He asked: 'How do you do that?' By using my heart antenna was the answer and anyone can do it. Heart-centred is how we are meant to be. With a closed heart chakra we withdraw into a closed mind and the bubble of five-sense reality. If you take a moment to focus your attention on the centre of your chest, picture a spinning wheel of light and see it opening and expanding. You will feel it happening, too, and perceptions of the heart like joy and love as the heart impacts on the mind as they interact. The more the chakra opens the more you will feel expressions of heart consciousness and as the process continues, and becomes part of you, insights and knowings will follow. An open heart is connected to that level of awareness that knows all is *One*. You will see from its perspective that the fault-lines that divide us are only illusions to control us. An open heart does not process the illusions of race, creed and sexuality except as brief experiences for a consciousness that is all. Our heart does not see division, only unity (Figs 24 and 25). There's something else, too. Our hearts love to laugh. Mark Twain's quote that says 'The human race has one really effective weapon, and that is laughter' is really a reference to the heart which loves to laugh with the joy of knowing the true nature of infinite reality and that all the madness of human society is an illusion of the mind. Twain also said: 'Against the assault of laughter nothing can stand.' This is so true of Wetiko and the Cult. Their insecurity demands that they be taken seriously and their power and authority acknowledged and feared. We should do nothing of the sort. We should not get aggressive or fearful which their insecurity so desires. We should laugh in their face. Even in their no-face as police come over in their face-nappies and expect to be taken seriously. They don't take themselves seriously looking like that so why should we? Laugh in the face of intimidation. Laugh in the face of tyranny. You will see by its reaction that you have pressed all of its buttons. Wetiko does not know what to do in the face of laughter or when its targets refuse to concede their joy to fear. We have seen many examples during the 'Covid' hoax when people have expressed their energetic power and the string puppets of Wetiko retreat with their tail limp between their knees. Laugh – the world is bloody mad after all and if it's a choice between laughter and tears I know which way I'm going.

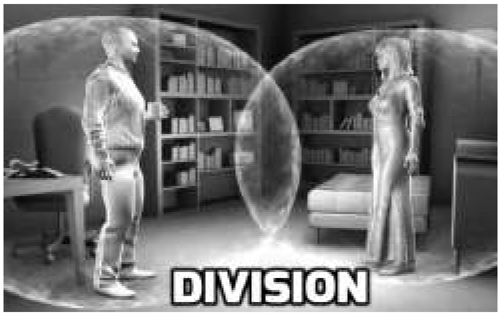

Figure 24: Head consciousness without the heart sees division and everything apart from everything else.

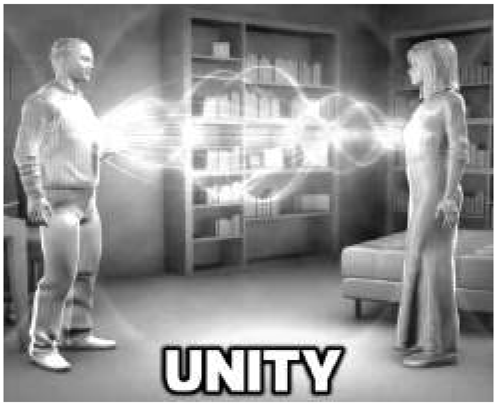

Figure 25: Heart consciousness sees everything as One.

'Vaccines' and the soul

The foundation of Wetiko/Archon control of humans is the separation of incarnate five-sense mind from the infinite 'I' and closing the heart chakra where the True 'I' lives during a human life. The goal has been to achieve complete separation in both cases. I was interested therefore to read an account by a French energetic healer of what she said she experienced with a patient who had been given the 'Covid' vaccine. Genuine energy healers can sense information and consciousness fields at different levels of being which are referred to as 'subtle bodies'. She described treating the patient who later returned after having, without the healer's knowledge, two doses of the 'Covid vaccine'. The healer said:

> I noticed immediately the change, very heavy energy emanating from [the] subtle bodies. The scariest thing was when I was working on the heart chakra, I connected with her soul: it was detached from the physical body, it had no contact and it was, as if it was floating in a state of total confusion: a damage to the consciousness that loses contact with the physical body, i.e. with our biological machine, there is no longer any communication between them.
>
> I continued the treatment by sending light to the heart chakra, the soul of the person, but it seemed that the soul could no longer receive any light, frequency or energy. It was a very powerful experience for me. Then I understood that this substance is indeed used to detach consciousness so that this consciousness can no longer interact through this body that it possesses in life, where there is no longer any contact, no frequency, no light, no more energetic balance or mind.

This would create a human that is rudderless and at the extreme almost zombie-like operating with a fractional state of consciousness at the mercy of Wetiko. I was especially intrigued by what the healer said in the light of the prediction by the highly-informed Rudolf Steiner more than a hundred years ago. He said:

> In the future, we will eliminate the soul with medicine. Under the pretext of a 'healthy point of view', there will be a vaccine by which the human body will be treated as soon as possible directly at birth, so that the human being cannot develop the thought of the existence of soul and Spirit. To materialistic doctors will be entrusted the task of removing the soul of humanity.
>
> As today, people are vaccinated against this disease or that disease, so in the future, children will be vaccinated with a substance that can be produced precisely in such a way that people, thanks to this vaccination, will be immune to being subjected to the 'madness' of spiritual life. He would be extremely smart, but he would not develop a conscience, and that is the true goal of some materialistic circles.

Steiner said the vaccine would detach the physical body from the etheric body (subtle bodies) and 'once the etheric body is detached the relationship between the universe and the etheric body would become extremely unstable, and man would become an automaton'. He said 'the physical body of man must be polished on this Earth by spiritual will – so the vaccine becomes a kind of arymanique (Wetiko) force' and 'man can no longer get rid of a given materialistic feeling'. Humans would then, he said, become 'materialistic of constitution and can no longer rise to the spiritual'. I have been writing for years about DNA being a receiver-transmitter of information that connects us to other levels of reality and these 'vaccines' changing DNA can be likened to changing an antenna and what it can transmit and receive. Such a disconnection would clearly lead to changes in personality and perception. Steiner further predicted the arrival of AI. Big Pharma 'Covid vaccine' makers, expressions of Wetiko, are testing their DNA-manipulating evil on children as I write with a view to giving the 'vaccine' to babies. If it's a soul-body disconnector – and I say that it is or can be – every child would be disconnected from 'soul' at birth and the 'vaccine' would create a closed system in which spiritual guidance from the greater self would play no part. This has been the ambition of Wetiko all along. A Pentagon video from 2005 was leaked of a presentation explaining the development of vaccines to change behaviour by their effect on the brain. Those that believe this is not happening with the 'Covid' genetically-modifying procedure masquerading as a 'vaccine' should make an urgent appointment with Naivety Anonymous. Klaus Schwab wrote in 2018:

> Neurotechnologies enable us to better influence consciousness and thought and to understand many activities of the brain. They include decoding what we are thinking in fine levels of detail through new chemicals and interventions that can influence our brains to correct for errors or enhance functionality.

The plan is clear and only the heart can stop it. With every heart that opens, every mind that awakens, Wetiko is weakened. Heart and love are far more powerful than head and hate and so nothing like a majority is needed to turn this around.

Beyond the Phantom

Our heart is the prime target of Wetiko and so it must be the answer to Wetiko. We *are* our heart which is part of one heart, the infinite heart. Our heart is where the true self lives in a human life behind firewalls of five-sense illusion when an imposter takes its place – *Phantom Self*; but our heart waits patiently to be set free any time we choose to see beyond the Phantom, beyond Wetiko. A Wetikoed Phantom Self can wreak mass death and destruction while the love of forever is locked away in its heart. The time is here to unleash its power and let it sweep away the fear and despair that is Wetiko. Heart consciousness does not seek manipulated, censored, advantage for its belief or religion, its activism and desires. As an expression of the One it treats all as One with the same rights to freedom and opinion. Our heart demands fairness for itself no more than for others. From this unity of heart we can come together in mutual support and transform this Wetikoed world into what reality is meant to be – a place of love, joy, happiness, fairness, justice and freedom. Wetiko has another agenda and that's why the world is as it is, but enough of this nonsense. Wetiko can't stay where hearts are open and it works so hard to keep them closed. Fear is its currency and its food source and love in its true sense has no fear. Why would love have fear when it knows it is *All That Is, Has Been, And Ever Can Be* on an eternal exploration of all possibility? Love in this true sense is not the physical attraction that passes for love. This can be an expression of it, yes, but Infinite Love, a love without condition, goes far deeper to the core of all being. It *is* the core of all being. Infinite realty was born from love beyond the illusions of the simulation. Love infinitely expressed is the knowing that all is One and the swiftly-passing experience of separation is a temporary hallucination. You cannot disconnect from Oneness; you can only *perceive* that you have and withdraw from its influence. This is the most important of all perception trickery by the mind parasite that is Wetiko and the foundation of all its potential for manipulation.

If we open our hearts, open the sluice gates of the mind, and redefine self-identity amazing things start to happen. Consciousness expands or contracts in accordance with self-identity. When true self is recognised as infinite awareness and label self – Phantom Self – is seen as only a series of brief experiences life is transformed. Consciousness expands to the extent that self-identity expands and everything changes. You see unity, not division, the picture, not the pixels. From this we can play the long game. No more is an experience something in and of itself, but a fleeting moment in the eternity of forever. Suddenly people in uniform and dark suits are no longer intimidating. Doing what your heart knows to be right is no longer intimidating and consequences for those actions take on the same nature of a brief experience that passes in the blink of an infinite eye. Intimidation is all in the mind. Beyond the mind there is no intimidation.

An open heart does not consider consequences for what it knows to be right. To do so would be to consider not doing what it knows to be right and for a heart in its power that is never an option. The Renegade Mind is really the Renegade Heart. Consideration of consequences will always provide a getaway car for the mind and the heart doesn't want one. What is right in the light of what we face today is to stop cooperating with Wetiko in all its forms and to do it without fear or compromise. You cannot compromise with tyranny when tyranny always demands more until it has everything. Life is your perception and you are your destiny. Change your perception and you change your life. Change collective perception and we change the world.

Come on people … One human family, One heart, One goal … *FREEEEEEDOM*!

We must settle for nothing less.

Postscript

The big scare story as the book goes to press is the 'Indian' variant and the world is being deluged with propaganda about the 'Covid catastrophe' in India which mirrors in its lies and misrepresentations what happened in Italy before the first lockdown in 2020.

The *New York Post* published a picture of someone who had 'collapsed in the street from Covid' in India in April, 2021, which was actually taken during a gas leak in May, 2020. Same old, same old. Media articles in mid-February were asking why India had been so untouched by 'Covid' and then as their vaccine rollout gathered pace the alleged 'cases' began to rapidly increase. Indian 'Covid vaccine' maker Bharat Biotech was funded into existence by the Bill and Melinda Gates Foundation (the pair announced their divorce in May, 2021, which is a pity because they so deserve each other). The Indian 'Covid crisis' was ramped up by the media to terrify the world and prepare people for submission to still more restrictions. The scam that worked the first time was being repeated only with far more people seeing through the deceit. Davidicke.com and Ickonic.com have sought to tell the true story of what is happening by talking to people living through the Indian nightmare which has nothing to do with 'Covid'. We posted a letter from 'Alisha' in Pune who told a very different story to government and media mendacity. She said scenes of dying people and overwhelmed hospitals were designed to hide what was really happening – genocide and starvation. Alisha said that millions had already died of starvation during the ongoing lockdowns while government and media were lying and making it look like the 'virus':

> Restaurants, shops, gyms, theatres, basically everything is shut. The cities are ghost towns. Even so-called 'essential' businesses are only open till 11am in the morning. You basically have just an hour to buy food and then your time is up.
>
> Inter-state travel and even inter-district travel is banned. The cops wait at all major crossroads to question why you are traveling outdoors or to fine you if you are not wearing a mask.
>
> The medical community here is also complicit in genocide, lying about hospitals being full and turning away people with genuine illnesses, who need immediate care. They have even created a shortage of oxygen cylinders.

This is the classic Cult modus operandi played out in every country. Alisha said that people who would not have a PCR test not testing for the 'virus' were being denied hospital treatment. She said the people hit hardest were migrant workers and those in rural areas. Most businesses employed migrant workers and with everything closed there were no jobs, no income and no food. As a result millions were dying of starvation or malnutrition. All this was happening under Prime Minister Narendra Modi, a 100-percent asset of the Cult, and it emphasises yet again the scale of pure anti-human evil we are dealing with. Australia banned its people from returning home from India with penalties for trying to do so of up to five years in jail and a fine of £37,000. The manufactured 'Covid' crisis in India was being prepared to justify further fascism in the West. Obvious connections could be seen between the Indian 'vaccine' programme and increased 'cases' and this became a common theme. The Seychelles, the most per capita 'Covid vaccinated' population in the world, went back into lockdown after a 'surge of cases'.

Long ago the truly evil Monsanto agricultural biotechnology corporation with its big connections to Bill Gates devastated Indian farming with genetically-modified crops. Human rights activist Gurcharan Singh highlighted the efforts by the Indian government to complete the job by destroying the food supply to hundreds of millions with 'Covid' lockdowns. He said that 415 million people at the bottom of the disgusting caste system (still going whatever they say) were below the poverty line and struggled to feed themselves every year. Now the government was imposing lockdown at just the time to destroy the harvest. This deliberate policy was leading to mass starvation. People may reel back at the suggestion that a government would do that, but Wetiko-controlled ‘leaders’ are capable of any level of evil. In fact what is described in India is in the process of being instigated worldwide. The food chain and food supply are being targeted at every level to cause world hunger and thus control. Bill Gates is not the biggest owner of farmland in America for no reason and destroying access to food aids both the depopulation agenda and the plan for synthetic ‘food’ already being funded into existence by Gates. Add to this the coming hyper-inflation from the suicidal creation of fake ‘money’ in response to ‘Covid’ and the breakdown of container shipping systems and you have a cocktail that can only lead one way and is meant to. The Cult plan is to crash the entire system to ‘build back better’ with the Great Reset.

‘Vaccine’ transmission

Reports from all over the world continue to emerge of women suffering menstrual and fertility problems after having the fake ‘vaccine’ and of the non-’vaccinated’ having similar problems when interacting with the ‘vaccinated’. There are far too many for ‘coincidence’ to be credible. We’ve had menopausal women getting periods, others having periods stop or not stopping for weeks, passing clots, sometimes the lining of the uterus, breast irregularities, and miscarriages (which increased by 400 percent in parts of the United States). Non-‘vaccinated’ men and children have suffered blood clots and nose bleeding after interaction with the ‘vaccinated’. Babies have died from the effects of breast milk from a ‘vaccinated’ mother. Awake doctors – the small minority – speculated on the cause of non-’vaccinated’ suffering the same effects as the ‘vaccinated’. Was it nanotechnology in the synthetic substance transmitting frequencies or was it a straight chemical bioweapon that was being transmitted between people? I am not saying that some kind of chemical transmission is not one possible answer, but the foundation of all that the Cult does is frequency and this is fertile ground for understanding how transmission can happen. American doctor Carrie Madej, an internal medicine physician and osteopath, has been practicing for the last 20 years, teaching medical students, and she says attending different meetings where the agenda for humanity was discussed. Madej, who operates out of Georgia, did not dismiss other possible forms of transmission, but she focused on frequency in search of an explanation for transmission. She said the Moderna and Pfizer 'vaccines' contained nano-lipid particles as a key component. This was a brand new technology never before used on humanity. 'They're using a nanotechnology which is pretty much little tiny computer bits … nanobots or hydrogel.' Inside the 'vaccines' was 'this sci-fi kind of substance' which suppressed immune checkpoints to get into the cell. I referred to this earlier as the 'Trojan horse' technique that tricks the cell into opening a gateway for the self-replicating synthetic material and while the immune system is artificially suppressed the body has no defences. Madej said the substance served many purposes including an on-demand ability to 'deliver the payload' and using the nano 'computer bits' as biosensors in the body. 'It actually has the ability to accumulate data from your body, like your breathing, your respiration, thoughts, emotions, all kinds of things.'

She said the technology obviously has the ability to operate through Wi-Fi and transmit and receive energy, messages, frequencies or impulses. 'Just imagine you're getting this new substance in you and it can react to things all around you, the 5G, your smart device, your phones.' We had something completely foreign in the human body that had never been launched large scale at a time when we were seeing 5G going into schools and hospitals (plus the Musk satellites) and she believed the 'vaccine' transmission had something to do with this: '… if these people have this inside of them … it can act like an antenna and actually transmit it outwardly as well.' The synthetic substance produced its own voltage and so it could have that kind of effect. This fits with my own contention that the nano receiver-transmitters are designed to connect people to the

Smart Grid and break the receiver-transmitter connection to expanded consciousness. That would explain the French energy healer's experience of the disconnection of body from 'soul' with those who have had the 'vaccine'. The nanobots, self-replicating inside the body, would also transmit the synthetic frequency which could be picked up through close interaction by those who have not been 'vaccinated'. Madej speculated that perhaps it was 5G and increased levels of other radiation that was causing the symptoms directly although interestingly she said that non-'vaccinated' patients had shown improvement when they were away from the 'vaccinated' person they had interacted with. It must be remembered that you can control frequency and energy with your mind and you can consciously create energetic barriers or bubbles with the mind to stop damaging frequencies from penetrating your field. American paediatrician Dr Larry Palevsky said the 'vaccine' was not a 'vaccine' and was never designed to protect from a 'viral' infection. He called it 'a massive, brilliant propaganda of genocide' because they didn't have to inject everyone to get the result they wanted. He said the content of the jabs was able to infuse any material into the brain, heart, lungs, kidneys, liver, sperm and female productive system. 'This is genocide; this is a weapon of mass destruction.' At the same time American colleges were banning students from attending if they didn't have this life-changing and potentially life-ending 'vaccine'. Class action lawsuits must follow when the consequences of this college fascism come to light. As the book was going to press came reports about fertility effects on sperm in 'vaccinated' men which would absolutely fit with what I have been saying and hospitals continued to fill with 'vaccine' reactions. Another question is what about transmission via blood transfusions? The NHS has extended blood donation restrictions from seven days after a 'Covid vaccination' to 28 days after even a sore arm reaction.

I said in the spring of 2020 that the then touted 'Covid vaccine' would be ongoing each year like the flu jab. A year later Pfizer CEO, the appalling Albert Bourla, said people would 'likely' need a 'booster dose' of the 'vaccine' within 12 months of getting 'fully vaccinated' and then a yearly shot. 'Variants will play a key role', he said confirming the point. Johnson & Johnson CEO Alex Gorsky also took time out from his 'vaccine' disaster to say that people may need to be vaccinated against 'Covid-19' each year. UK Health Secretary, the psychopath Matt Hancock, said additional 'boosters' would be available in the autumn of 2021. This is the trap of the 'vaccine passport'. The public will have to accept every last 'vaccine' they introduce, including for the fake 'variants', or it would cease to be valid. The only other way in some cases would be continuous testing with a test not testing for the 'virus' and what is on the swabs constantly pushed up your noise towards the brain every time?

'Vaccines' changing behaviour

I mentioned in the body of the book how I believed we would see gathering behaviour changes in the 'vaccinated' and I am already hearing such comments from the non-'vaccinated' describing behaviour changes in friends, loved ones and work colleagues. This will only increase as the self-replicating synthetic material and nanoparticles expand in body and brain. An article in the *Guardian* in 2016 detailed research at the University of Virginia in Charlottesville which developed a new method for controlling brain circuits associated with complex animal behaviour. The method, dubbed 'magnetogenetics', involves genetically-engineering a protein called ferritin, which stores and releases iron, to create a magnetised substance – 'Magneto' – that can activate specific groups of nerve cells from a distance. This is claimed to be an advance on other methods of brain activity manipulation known as optogenetics and chemogenetics (the Cult has been developing methods of brain control for a long time). The ferritin technique is said to be non-invasive and able to activate neurons 'rapidly and reversibly'. In other words, human thought and perception. The article said that earlier studies revealed how nerve cell proteins 'activated by heat and mechanical pressure can be genetically engineered so that they become sensitive to radio waves and magnetic fields, by attaching them to an iron-storing protein called ferritin, or to inorganic paramagnetic particles'. Sensitive to radio waves and magnetic fields? You mean like 5G, 6G and 7G? This is the human-AI Smart Grid hive mind we are talking about. The *Guardian* article said:

> … the researchers injected Magneto into the striatum of freely behaving mice, a deep brain structure containing dopamine-producing neurons that are involved in reward and motivation, and then placed the animals into an apparatus split into magnetised and non-magnetised sections.
>
> Mice expressing Magneto spent far more time in the magnetised areas than mice that did not, because activation of the protein caused the striatal neurons expressing it to release dopamine, so that the mice found being in those areas rewarding. This shows that Magneto can remotely control the firing of neurons deep within the brain, and also control complex behaviours.

Make no mistake this basic methodology will be part of the 'Covid vaccine' cocktail and using magnetics to change brain function through electromagnetic field frequency activation. The Pentagon is developing a 'Covid vaccine' using ferritin. Magnetics would explain changes in behaviour and why videos are appearing across the Internet as I write showing how magnets stick to the skin at the point of the 'vaccine' shot. Once people take these 'vaccines' anything becomes possible in terms of brain function and illness which will be blamed on 'Covid-19' and 'variants'. Magnetic field manipulation would further explain why the non-'vaccinated' are reporting the same symptoms as the 'vaccinated' they interact with and why those symptoms are reported to decrease when not in their company. Interestingly 'Magneto', a 'mutant', is a character in the Marvel Comic *X-Men* stories with the ability to manipulate magnetic fields and he believes that mutants should fight back against their human oppressors by any means necessary. The character was born Erik Lehnsherr to a Jewish family in Germany.

Cult-controlled courts

The European Court of Human Rights opened the door for mandatory 'Covid-19 vaccines' across the continent when it ruled in a Czech Republic dispute over childhood immunisation that legally enforced vaccination could be ‘necessary in a democratic society’. The 17 judges decided that compulsory vaccinations did not breach human rights law. On the face of it the judgement was so inverted you gasp for air. If not having a vaccine infused into your body is not a human right then what is? Ah, but they said human rights law which has been specifically written to delete all human rights at the behest of the state (the Cult). Article 8 of the European Convention on Human Rights relates to the right to a private life. The crucial word here is *‘except’*:

> There shall be no interference by a public authority with the exercise of this right EXCEPT such as is in accordance with the law and is necessary in a democratic society in the interests of national security, public safety or the economic wellbeing of the country, for the prevention of disorder or crime, for the protection of health or morals, or for the protection of the rights and freedoms of others [My emphasis].

No interference *except* in accordance with the law means there *are* no ‘human rights’ *except* what EU governments decide you can have at their behest. ‘As is necessary in a democratic society’ explains that reference in the judgement and ‘in the interests of national security, public safety or the economic well-being of the country, for the prevention of disorder or crime, for the protection of health or morals, or for the protection of the rights and freedoms of others’ gives the EU a coach and horses to ride through ‘human rights’ and scatter them in all directions. The judiciary is not a check and balance on government extremism; it is a vehicle to enforce it. This judgement was almost laughably predictable when the last thing the Cult wanted was a decision that went against mandatory vaccination. Judges rule over and over again to benefit the system of which they are a part. Vaccination disputes that come before them are invariably delivered in favour of doctors and authorities representing the view of the state which owns the judiciary. Oh, yes, and we have even had calls to stop putting ‘Covid-19’ on death certificates within 28 days of a ‘positive test’ because it is claimed the practice makes the ‘vaccine’ appear not to work. They are laughing at you.

The scale of madness, inhumanity and things to come was highlighted when those not 'vaccinated' for 'Covid' were refused evacuation from the Caribbean island of St Vincent during massive volcanic eruptions. Cruise ships taking residents to the safety of another island allowed only the 'vaccinated' to board and the rest were left to their fate. Even in life and death situations like this we see 'Covid' stripping people of their most basic human instincts and the insanity is even more extreme when you think that fake 'vaccine'-makers are not even claiming their body-manipulating concoctions stop 'infection' and 'transmission' of a 'virus' that doesn't exist. St Vincent Prime Minister Ralph Gonsalves said: 'The chief medical officer will be identifying the persons already vaccinated so that we can get them on the ship.' Note again the power of the chief medical officer who, like Whitty in the UK, will be answering to the World Health Organization. This is the Cult network structure that has overridden politicians who 'follow the science' which means doing what WHO-controlled 'medical officers' and 'science advisers' tell them. Gonsalves even said that residents who were 'vaccinated' after the order so they could board the ships would still be refused entry due to possible side effects such as 'wooziness in the head'. The good news is that if they were woozy enough in the head they could qualify to be prime minister of St Vincent.

Microchipping freedom

The European judgement will be used at some point to justify moves to enforce the 'Covid' DNA-manipulating procedure. Sandra Ro, CEO of the Global Blockchain Business Council, told a World Economic Forum event that she hoped 'vaccine passports' would help to 'drive forced consent and standardisation' of global digital identity schemes: 'I'm hoping with the desire and global demand for some sort of vaccine passport – so that people can get travelling and working again – [it] will drive forced consent, standardisation, and frankly, cooperation across the world.' The lady is either not very bright, or thoroughly mendacious, to use the term 'forced consent'.

You do not 'consent' if you are forced – you *submit*. She was describing what the plan has been all along and that's to enforce a digital identity on every human without which they could not function. 'Vaccine passports' are opening the door and are far from the end goal. A digital identity would allow you to be tracked in everything you do in cyberspace and this is the same technique used by Cult-owned China to enforce its social credit system of total control. The ultimate 'passport' is planned to be a microchip as my books have warned for nearly 30 years. Those nice people at the Pentagon working for the Cult-controlled Defense Advanced Research Projects Agency (DARPA) claimed in April, 2021, they have developed a microchip inserted under the skin to detect 'asymptomatic Covid-19 infection' before it becomes an outbreak and a 'revolutionary filter' that can remove the 'virus' from the blood when attached to a dialysis machine. The only problems with this are that the 'virus' does not exist and people transmitting the 'virus' with no symptoms is brain-numbing bullshit. This is, of course, not a ruse to get people to be microchipped for very different reasons. DARPA also said it was producing a one-stop 'vaccine' for the 'virus' and all 'variants'. One of the most sinister organisations on Planet Earth is doing this? Better have it then. These people are insane because Wetiko that possesses them is insane.

Researchers from the Salk Institute in California announced they have created an embryo that is part human and part monkey. My books going back to the 1990s have exposed experiments in top secret underground facilities in the United States where humans are being crossed with animal and non-human 'extraterrestrial' species. They are now easing that long-developed capability into the public arena and there is much more to come given we are dealing with psychiatric basket cases. Talking of which – Elon Musk's scientists at Neuralink trained a monkey to play Pong and other puzzles on a computer screen using a joystick and when the monkey made the correct move a metal tube squirted banana smoothie into his mouth which is the basic technique for training humans into unquestioning compliance. Two Neuralink chips were in the monkey's skull and more than 2,000 wires 'fanned out' into its brain. Eventually the monkey played a video game purely with its brain waves. Psychopathic narcissist Musk said the 'breakthrough' was a step towards putting Neuralink chips into human skulls and merging minds with artificial intelligence. *Exactly*. This man is so dark and Cult to his DNA.

World Economic Fascism (WEF)

The World Economic Forum is telling you the plan by the statements made at its many and various events. Cult-owned fascist YouTube CEO Susan Wojcicki spoke at the 2021 WEF Global Technology Governance Summit (see the name) in which 40 governments and 150 companies met to ensure 'the responsible design and deployment of emerging technologies'. Orwellian translation: 'Ensuring the design and deployment of long-planned technologies will advance the Cult agenda for control and censorship.' Freedom-destroyer and Nuremberg-bound Wojcicki expressed support for tech platforms like hers to censor content that is 'technically legal but could be harmful'. Who decides what is 'harmful'? She does and they do. 'Harmful' will be whatever the Cult doesn't want people to see and we have legislation proposed by the UK government that would censor content on the basis of 'harm' no matter if the information is fair, legal and provably true. Make that *especially* if it is fair, legal and provably true. Wojcicki called for a global coalition to be formed to enforce content moderation standards through automated censorship. This is a woman and mega-censor so self-deluded that she shamelessly accepted a 'free expression' award – *Wojcicki* – in an event sponsored by her own *YouTube*. They have no shame and no self-awareness.

You know that 'Covid' is a scam and Wojcicki a Cult operative when YouTube is censoring medical and scientific opinion purely on the grounds of whether it supports or opposes the Cult 'Covid' narrative. Florida governor Ron DeSantis compiled an expert panel with four professors of medicine from Harvard, Oxford, and Stanford Universities who spoke against forcing children and vaccinated people to wear masks. They also said there was no proof that lockdowns reduced spread or death rates of 'Covid-19'. Cult-gofer Wojcicki and her YouTube deleted the panel video 'because it included content that contradicts the consensus of local and global health authorities regarding the efficacy of masks to prevent the spread of Covid-19'. This 'consensus' refers to what the Cult tells the World Health Organization to say and the WHO tells 'local health authorities' to do. Wojcicki knows this, of course. The panellists pointed out that censorship of scientific debate was responsible for deaths from many causes, but Wojcicki couldn't care less. She would not dare go against what she is told and as a disgrace to humanity she wouldn't want to anyway. The UK government is seeking to pass a fascist 'Online Safety Bill' to specifically target with massive fines and other means non-censored video and social media platforms to make them censor 'lawful but harmful' content like the Cult-owned Facebook, Twitter, Google and YouTube. What is 'lawful but harmful' would be decided by the fascist Blair-created Ofcom.

Another WEF obsession is a cyber-attack on the financial system and this is clearly what the Cult has planned to take down the bank accounts of everyone – except theirs. Those that think they have enough money for the Cult agenda not to matter to them have got a big lesson coming if they continue to ignore what is staring them in the face. The World Economic Forum, funded by Gates and fronted by Klaus Schwab, announced it would be running a 'simulation' with the Russian government and global banks of just such an attack called Cyber Polygon 2021. What they simulate – as with the 'Covid' Event 201 – they plan to instigate. The WEF is involved in a project with the Cult-owned Carnegie Endowment for International Peace called the WEF-Carnegie Cyber Policy Initiative which seeks to merge Wall Street banks, 'regulators' (I love it) and intelligence agencies to 'prevent' (arrange and allow) a cyber-attack that would bring down the global financial system as long planned by those that control the WEF and the Carnegie operation. The Carnegie Endowment for International Peace sent an instruction to First World

War US President Woodrow Wilson not to let the war end before society had been irreversibly transformed.

The Wuhan lab diversion

As I close, the Cult-controlled authorities and lapdog media are systematically pushing 'the virus was released from the Wuhan lab' narrative. There are two versions – it happened by accident and it happened on purpose. Both are nonsense. The perceived existence of the never-shown-to-exist 'virus' is vital to sell the impression that there is actually an infective agent to deal with and to allow the endless potential for terrifying the population with 'variants' of a 'virus' that does not exist. The authorities at the time of writing are going with the 'by accident' while the alternative media is promoting the 'on purpose'. Cable news host Tucker Carlson who has questioned aspects of lockdown and 'vaccine' compulsion has bought the Wuhan lab story. 'Everyone now agrees' he said. Well, I don't and many others don't and the question is *why* does the system and its media suddenly 'agree'? When the media moves as one unit with a narrative it is always a lie – witness the hour by hour mendacity of the 'Covid' era. Why would this Cult-owned combination which has unleashed lies like machine gun fire suddenly 'agree' to tell the truth??

Much of the alternative media is buying the lie because it fits the conspiracy narrative, but it's the *wrong* conspiracy. The real conspiracy is that *there is no virus* and that is what the Cult is desperate to hide. The idea that the 'virus' was released by accident is ludicrous when the whole 'Covid' hoax was clearly long-planned and waiting to be played out as it was so fast in accordance with the Rockefeller document and Event 201. So they prepared everything in detail over decades and then sat around strumming their fingers waiting for an 'accidental' release from a bio-lab? *What??* It's crazy. Then there's the 'on purpose' claim. You want to circulate a 'deadly virus' and hide the fact that you've done so and you release it down the street from the highest-level bio-lab in China? I repeat – *What??*

You would release it far from that lab to stop any association being made. But, no, we'll do it in a place where the connection was certain to be made. Why would you need to scam 'cases' and 'deaths' and pay hospitals to diagnose 'Covid-19' if you had a real 'virus'? What are sections of the alternative media doing believing this crap? Where were all the mass deaths in Wuhan from a 'deadly pathogen' when the recovery to normal life after the initial propaganda was dramatic in speed? Why isn't the 'deadly pathogen' now circulating all over China with bodies in the street? Once again we have the technique of tell them what they want to hear and they will likely believe it. The alternative media has its 'conspiracy' and with Carlson it fits with his 'China is the danger' narrative over years. China *is* a danger as a global Cult operations centre, but not for this reason. The Wuhan lab story also has the potential to instigate conflict with China when at some stage the plan is to trigger a Problem-Reaction-Solution confrontation with the West. Question everything – *everything* – and especially when the media agrees on a common party line.

Third wave ... fourth wave ... fifth wave ...

As the book went into production the world was being set up for more lockdowns and a 'third wave' supported by invented 'variants' that were increasing all the time and will continue to do so in public statements and computer programs, but not in reality. India became the new Italy in the 'Covid' propaganda campaign and we were told to be frightened of the new 'Indian strain'. Somehow I couldn't find it within myself to do so. A document produced for the UK government entitled 'Summary of further modelling of easing of restrictions – Roadmap Step 2' declared that a third wave was inevitable (of course when it's in the script) and it would be the fault of children and those who refuse the health-destroying fake 'Covid vaccine'. One of the computer models involved came from the Cult-owned *Imperial College* and the other from Warwick University which I wouldn't trust to tell me the date in a calendar factory. The document states that both models presumed extremely high uptake of the ‘Covid vaccines’ and didn’t allow for ‘variants’. The document states: ‘The resurgence is a result of some people (mostly children) being ineligible for vaccination; others choosing not to receive the vaccine; and others being vaccinated but not perfectly protected.’ The mendacity takes the breath away. Okay, blame those with a brain who won’t take the DNA-modifying shots and put more pressure on children to have it as ‘trials’ were underway involving children as young as six months with parents who give insanity a bad name. Massive pressure is being put on the young to have the fake ‘vaccine’ and child age consent limits have been systematically lowered around the world to stop parents intervening. Most extraordinary about the document was its claim that the ‘third wave’ would be driven by ‘the resurgence in both hospitalisations and deaths … dominated by *those that have received two doses of the vaccine*, comprising around 60-70% of the wave respectively’. The predicted peak of the ‘third wave’ suggested 300 deaths per day with 250 of them *fully ‘vaccinated’ people*. How many more lies do acquiescers need to be told before they see the obvious? Those who took the jab to ‘protect themselves’ are projected to be those who mostly get sick and die? So what’s in the ‘vaccine’? The document went on:

> It is possible that a summer of low prevalence could be followed by substantial increases in incidence over the following autumn and winter. Low prevalence in late summer should not be taken as an indication that SARS-CoV-2 has retreated or that the population has high enough levels of immunity to prevent another wave.

They are telling you the script and while many British people believed ‘Covid’ restrictions would end in the summer of 2021 the government was preparing for them to be ongoing. Authorities were awarding contracts for ‘Covid marshals’ to police the restrictions with contracts starting in July, 2021, and going through to January 31st, 2022, and the government was advertising for ‘Media Buying Services’ to secure media propaganda slots worth a potential £320 million for ‘Covid-19 campaigns’ with a contract not ending until March, 2022. The recipient – via a list of other front companies – was reported to be American media marketing giant Omnicom Group

Inc. While money is no object for 'Covid' the UK waiting list for all other treatment – including life-threatening conditions – passed 4.5 million. Meantime the Cult is seeking to control all official 'inquiries' to block revelations about what has really been happening and why. It must not be allowed to – we need Nuremberg jury trials in every country. The cover-up doesn't get more obvious than appointing ultra-Zionist professor Philip Zelikow to oversee two dozen US virologists, public health officials, clinicians, former government officials and four American 'charitable foundations' to 'learn the lessons' of the 'Covid' debacle. The personnel will be those that created and perpetuated the 'Covid' lies while Zelikow is the former executive director of the 9/11 Commission who ensured that the truth about those attacks never came out and produced a report that must be among the most mendacious and manipulative documents ever written – see *The Trigger* for the detailed exposure of the almost unimaginable 9/11 story in which Sabbatians can be found at every level.

Passive no more

People are increasingly challenging the authorities with amazing numbers of people taking to the streets in London well beyond the ability of the Face-Nappies to stop them. Instead the Nappies choose situations away from the mass crowds to target, intimidate, and seek to promote the impression of 'violent protestors'. One such incident happened in London's Hyde Park. Hundreds of thousands walking through the streets in protest against 'Covid' fascism were ignored by the Cult-owned BBC and most of the rest of the mainstream media, but they delighted in reporting how police were injured in 'clashes with protestors'. The truth was that a group of people gathered in Hyde Park at the end of one march when most had gone home and they were peacefully having a good time with music and chat. Face-Nappies who couldn't deal with the full-march crowd then waded in with their batons and got more than they bargained for. Instead of just standing for this criminal brutality the crowd used their numerical superiority to push the Face-Nappies out of the park. Eventually the Nappies turned and ran. Unfortunately two or three idiots in the crowd threw drink cans striking two officers which gave the media and the government the image they wanted to discredit the 99.9999 percent who were peaceful. The idiots walked straight into the trap and we must always be aware of potential agent provocateurs used by the authorities to discredit their targets.

This response from the crowd – the can people apart – must be a turning point when the public no longer stand by while the innocent are arrested and brutally attacked by the Face-Nappies. That doesn't mean to be violent, that's the last thing we need. We'll leave the violence to the Face-Nappies and government. But it does mean that when the Face-Nappies use violence against peaceful people the numerical superiority is employed to stop them and make citizen's arrests or Common Law arrests for a breach of the peace. The time for being passive in the face of fascism is over.

We are the many, they are the few, and we need to make that count before there is no freedom left and our children and grandchildren face an ongoing fascist nightmare.

COME ON PEOPLE – IT'S TIME.

One final thought …

The power of love
A force from above
Cleaning my soul
Flame on burn desire
Love with tongues of fire
Purge the soul
Make love your goal

I’ll protect you from the hooded claw
Keep the vampires from your door
When the chips are down I’ll be around
With my undying, death-defying
Love for you

Envy will hurt itself
Let yourself be beautiful
Sparkling love, flowers
And pearls and pretty girls
Love is like an energy
Rushin’ rushin’ inside of me

This time we go sublime
Lovers entwine, divine, divine,
Love is danger, love is pleasure
Love is pure – the only treasure

I’m so in love with you
Purge the soul
Make love your goal

The power of love
A force from above
Cleaning my soul
The power of love
A force from above
A sky-scraping dove

Flame on burn desire
Love with tongues of fire
Purge the soul
Make love your goal

Frankie Goes To Hollywood

APPENDIX

Cowan-Kaufman-Morell Statement on Virus Isolation (SOVI)

Isolation: The action of isolating; the fact or condition of being isolated or standing alone; separation from other things or persons; solitariness
Oxford English Dictionary

The controversy over whether the SARS-CoV-2 virus has ever been isolated or purified continues. However, using the above definition, common sense, the laws of logic and the dictates of science, any unbiased person must come to the conclusion that the SARS-CoV-2 virus has never been isolated or purified. As a result, no confirmation of the virus' existence can be found. The logical, common sense, and scientific consequences of this fact are:

- the structure and composition of something not shown to exist can't be known, including the presence, structure, and function of any hypothetical spike or other proteins;
- the genetic sequence of something that has never been found can't be known;
- "variants" of something that hasn't been shown to exist can't be known;
- it's impossible to demonstrate that SARS-CoV-2 causes a disease called Covid-19.

In as concise terms as possible, here's the proper way to isolate, characterize and demonstrate a new virus. First, one takes samples (blood, sputum, secretions) from many people (e.g. 500) with symptoms which are unique and specific enough to characterize an illness. Without mixing these samples with ANY tissue or products that also contain genetic material, the virologist macerates, filters and ultracentrifuges i.e. *purifies* the specimen. This common virology technique, done for decades to isolate bacteriophages[1] and so-called giant viruses in every virology lab, then allows the virologist to demonstrate with electron microscopy thousands of identically sized and shaped particles. These particles are the isolated and purified virus.

These identical particles are then checked for uniformity by physical and/or microscopic techniques. Once the purity is determined, the particles may be further characterized. This would include examining the structure, morphology, and chemical composition of the particles. Next, their genetic makeup is characterized by extracting the genetic material directly from the purified particles and using genetic-sequencing techniques, such as Sanger sequencing, that have also been around for decades. Then one does an analysis to confirm that these uniform particles are exogenous (outside) in origin as a virus is conceptualized to be, and not the normal breakdown products of dead and dying tissues.[2] (As of May 2020, we know that virologists have no way to determine whether the particles they're seeing are viruses or just normal break-down products of dead and dying tissues.)[3]

If we have come this far then we have fully isolated, characterized, and genetically sequenced an exogenous virus particle. However, we still have to show it is causally related to a disease. This is carried out by exposing a group of healthy subjects (animals are usually used) to this isolated, purified virus in the manner in which the disease is thought to be transmitted. If the animals get sick with the same disease, as confirmed by clinical and autopsy findings, one has now shown that the virus actually causes a disease. This demonstrates infectivity and transmission of an infectious agent.

None of these steps has even been attempted with the SARS-CoV-2 virus, nor have all these steps been successfully performed for any so-called pathogenic virus. Our research indicates that a single study showing these steps does not exist in the medical literature.

Instead, since 1954, virologists have taken unpurified samples from a relatively few people, often less than ten, with a similar disease. They then minimally process this sample and inoculate this unpurified sample onto tissue culture containing usually four to six other types of material – all of which contain identical genetic material as to what is called a “virus.” The tissue culture is starved and poisoned and naturally disintegrates into many types of particles, some of which contain genetic material. Against all common sense, logic, use of the English language and scientific integrity, this process is called “virus isolation.” This brew containing fragments of genetic material from many sources is then subjected to genetic analysis, which then creates in a computer-simulation process the alleged sequence of the alleged virus, a so called in silico genome. At no time is an actual virus confirmed by electron microscopy. At no time is a genome extracted and sequenced from an actual virus. This is scientific fraud.

---

3 “The Role of Extraellular Vesicles as Allies of HIV, HCV and SARS Viruses,” Flavia Giannessi, et al, Viruses, 2020 May

The observation that the unpurified specimen — inoculated onto tissue culture along with toxic antibiotics, bovine fetal tissue, amniotic fluid and other tissues — destroys the kidney tissue onto which it is inoculated is given as evidence of the virus' existence and pathogenicity. This is scientific fraud.

From now on, when anyone gives you a paper that suggests the SARS-CoV-2 virus has been isolated, please check the methods sections. If the researchers used Vero cells or any other culture method, you know that their process was not isolation. You will hear the following excuses for why actual isolation isn't done:

1. There were not enough virus particles found in samples from patients to analyze.

2. Viruses are intracellular parasites; they can't be found outside the cell in this manner.

If No. 1 is correct, and we can't find the virus in the sputum of sick people, then on what evidence do we think the virus is dangerous or even lethal? If No. 2 is correct, then how is the virus spread from person to person? We are told it emerges from the cell to infect others. Then why isn't it possible to find it?

Finally, questioning these virology techniques and conclusions is not some distraction or divisive issue. Shining the light on this truth is essential to stop this terrible fraud that humanity is confronting. For, as we now know, if the virus has never been isolated, sequenced or shown to cause illness, if the virus is imaginary, then why are we wearing masks, social distancing and putting the whole world into prison?

Finally, if pathogenic viruses don't exist, then what is going into those injectable devices erroneously called "vaccines," and what is their purpose? This scientific question is the most urgent and relevant one of our time.

We are correct. The SARS-CoV2 virus does not exist.

ICKONIC
THE ALTERNATIVE

Ickonic is something that has been a dream of mine for the last 5 years, growing up around alternative information I have always had a natural interest in what is going on in the World and what could I do to make it better.
Across the range of subjects and positions of influence occupied mainly by people who don't strive to make things better it's the Media that I have always found the most frustrating and fascinating. Mainly because if the Media did their Jobs properly then so much of the negative things happening in the World simply would not be able to happen, because they would be exposed within a heartbeat.
Free Press and the Opportunities that the internet could have given would mean that the Media are able to expose things like never before and hold people to account for their actions. As we all know there are 'Untouchables' that walk among us, people the Media simply won't touch, expose or investigate and that leads to the dark underworlds that infest the establishment the World over.
Well I say enough, it's time for something different, a different kind of Media, where no one is off limits from exposing and investigating. All we're interested in at Ickonic is the truth of what is really going on in the World on whichever subject we're covering.
We hope you enjoy what we have created and take something away from the platform, we aim to deliver information that's informative and most importantly self-empowering, you're not a little person, you're part of something much bigger than that and its time we as a collective race began to understand that and look to the future as ours to take.

It's time...

Jaymie Icke - Founder Ickonic Alternative Media.

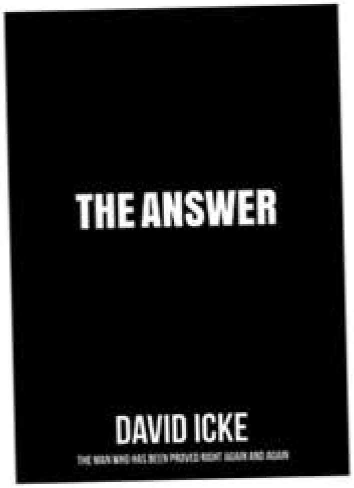
DAVID ICKE

THE ANSWER



THE ANSWER

DAVID ICKE

THE MAN WHO HAS BEEN PROVED RIGHT AGAIN AND AGAIN

We live in extraordinary times with billions bewildered and seeking answers for what is happening. David Icke, the man who has been proved right again and again, has spent 30 years uncovering the truth behind world affairs and in a stream of previous books he predicted current events.

The Answer will change your every perception of life and the world and set you free of the illusions that control human society. There is nothing more vital for our collective freedom than humanity becoming aware of what is in this book.

Available now at davidicke.com.

Series Preface

This international series covers all aspects of theoretical and applied optics and optoelectronics. Active since 1986, eminent authors have long been choosing to publish with this series, and it is now established as a premier forum for high-impact monographs and textbooks. The editors are proud of the breadth and depth showcased by the published works, with levels ranging from advanced undergraduate and graduate student texts to professional references. Topics addressed are both cutting edge and fundamental, basic science and applications-oriented, on subject matter that includes lasers, photonic devices, nonlinear optics, interferometry, waves, crystals, optical materials, biomedical optics, optical tweezers, optical metrology, solid-state lighting, nanophotonics, and silicon photonics. Readers of the series are students, scientists, and engineers working in optics, optoelectronics, and related fields in the industry.

Proposals for new volumes in the series may be directed to Lu Han, senior publishing editor at CRC Press/Taylor & Francis Group (lu.han@taylorandfrancis.com).

Preface

Optoelectronic devices have become ubiquitous in our daily lives. For example, light-emitting diodes (LEDs) are used in almost all household appliances, in traffic and streetlights, and in full-color displays. Laser diodes, optical modulators, and photodetectors are key components of the Internet. Solar cells are core elements of energy supply systems. Optoelectronic devices are typically based on nanoscale semiconductor structures that utilize the interaction of electrons and photons. The underlying and highly complex physical processes require mathematical models and numerical simulation for device design, analysis, and performance optimization. This handbook gives an introduction to modern optoelectronic devices, models, and simulation methods.

Driven by the expanding diversity of available and envisioned practical applications, mathematical models and numerical simulation software for optoelectronic devices have experienced a rapid development in recent years. In the past, advanced modeling and simulation was the domain of a few specialists using proprietary software in computational research groups. The increasing user-friendliness of commercial software now also opens the door for nontheoreticians and experimentalists to perform sophisticated modeling and simulation tasks. However, the ever-growing variety and complexity of devices, materials, physical mechanisms, theoretical models, and numerical techniques make it often difficult to identify the best approach to a given project or problem. This book presents an up-to-date review of optoelectronic device models and numerical techniques. The handbook format is ideal for beginners but also gives experienced researchers an opportunity to renew and broaden their knowledge in this expanding field.

Semiconductors are the key material of optoelectronic devices, as they enable propagation and interaction of electrons and photons. The handbook starts with an overview of fundamental semiconductor device models, which apply to almost all device types, followed by sections on novel materials and nanostructures. The main part of the handbook is ordered by device type (LED, amplifier, laser diode, photodetector, and solar cell). For each device type, an introductory chapter is followed by chapters on specialized device designs and applications, describing characteristic effects and models. Finally, novel device concepts and applications are reviewed. At the end of the handbook, an overview of numerical techniques is provided, both for electronic and photonic simulations.

I would like to thank the publisher for initiating this important handbook project and for giving me the opportunity to serve as editor. Many years of organizing the annual international conference on *Numerical Simulation of Optoelectronic Devices (NUSOD)* enabled me to attract a large number of experts from all over the world to write handbook chapters on their research area. I sincerely thank all authors for their valuable contributions.

Editor

Joachim Piprek received his diploma and doctoral degrees in physics from the Humboldt University in Berlin, Germany. For more than two decades, he worked in industry and academia on modeling, simulation, and analysis of various semiconductor devices used in optoelectronics. Currently, he serves as president of the NUSOD Institute, Newark, Delaware (see http://www.nusod.org). During his previous career in higher education, Dr. Piprek taught various graduate courses at universities in Germany, Sweden, and the United States. Since 2001, he has been organizing the annual international conference on *Numerical Simulation of Optoelectronic Devices (NUSOD)*. Thus far, Dr. Piprek has published three books, six book chapters, and about 250 research papers, which have received more than 6000 citations. He was an invited guest editor for several journal issues on optoelectronic device simulation and currently serves as an executive/associate editor of two research journals in this field.

26.1 Introduction

Semiconductor laser diodes are key components in optical fiber communication, data storage, sensing, material processing, and other applications. They are based on sophisticated interactions of electrons and photons in semiconductor nanostructures (see Chapter 3). Advanced theoretical models and simulation tools are required for the development and analysis of future generations of laser diodes. The following chapters describe some of these complex models in detail. This introductory chapter is aimed at readers who are not yet familiar with basic models and parameters of semiconductor lasers. By exploring simple analytical models, this chapter tries to develop an intuitive understanding of internal laser physics that will help to digest the more complicated theory outlined in subsequent chapters. While these analytical models are quite popular, they often have limits beyond which numerical simulations are required, as shown below.

Section 26.2 examines basic formulas for optical gain and optical losses in semiconductor lasers, followed by the introduction of key performance parameters, threshold current, and slope efficiency. As practical applications often suffer from undesired self-heating of the laser, temperature effects are discussed in Section 26.4 and the resulting changes in laser efficiency in Section 26.5. The rate equation model for dynamic lasing processes is introduced in Section 26.6, including formulas for small signal analysis. Section 26.7 briefly reviews basic laser cavity designs.

26.2 Optical Gain and Optical Loss

Traveling through a semiconductor, a single photon with an energy close to the band gap is able to generate an identical second photon by stimulating the recombination of an electron–hole pair. This is the basic physical mechanism of lasing. The second photon exhibits the same wavelength and the same phase as of the first photon, doubling the amplitude of their monochromatic wave. Subsequent repetition of this process leads to strong light amplification. However, the competing process is the absorption of photons by the generation of new electron–hole pairs (see Figure 26.1). Stimulated emission prevails when more electrons are present at the higher energy level (conduction band) than at the lower energy level (valence band).

FIGURE 26.1 Electron–hole recombination and generation mechanisms in semiconductors. (SRH, Shockley–Read–Hall.)

This population inversion is one of the key requirements for lasing. Semiconductor lasers typically employ *pin* junctions with a thin active layer of lower band gap (Figure 26.2). At forward bias, electrons and holes are collected in the active layer to achieve inversion. Continuous current injection into the device leads to a continuous stimulated emission of photons, but only if enough photons are constantly present in the device to trigger this process. Thus, only part of all photons can be allowed to leave the laser diode as a lasing beam, the rest must be reflected to remain inside the diode and to generate new photons (Figure 26.3). This optical feedback and confinement of photons in an optical resonator is the second basic requirement of lasing.

The light amplification in the active layer is described by the optical gain $g(n, p, T, \lambda, S)$ as a function of the density of electrons n and holes p inside the active layer, the optical wavelength λ (or photon energy), the photon density S, and the temperature T. This gain function is the heart of laser physics, and a realistic calculation may require sophisticated models (see Chapter 3 for details). We here briefly discuss some popular analytical approximations. The linear gain approximation $g(N) = a(N - N_{\mathrm{tr}})$ is often used, employing the transparency density N_{tr} and assuming a fixed differential gain $a = \mathrm{d}g/\mathrm{d}N$ as well as identical densities of electrons and holes ($N = n = p$). For $N = N_{\mathrm{tr}}$, the absorption and gain are the same and the material is transparent. The differential gain $\mathrm{d}g/\mathrm{d}N$ is a key parameter for laser light modulation (which is discussed Section 26.6). It can only be considered constant for small variations of the carrier density since $\mathrm{d}g/\mathrm{d}N$ is known to decline with increasing carrier densities (Figure 26.4). This is described by the more general logarithmic function (Coldren and Corzine 1995)

$$g(N, S) = \frac{g_{\mathrm{o}}}{1 + \varepsilon S} \ln\left(\frac{N + N_{\mathrm{s}}}{N_{\mathrm{tr}} + N_{\mathrm{s}}}\right) \tag{26.1}$$

The gain compression factor ε describes the gain saturation at high photon densities, e.g., due to carrier depletion (g_{o} and N_{s} are fit parameters). All parameters in Equation 26.1 need to be extracted from more fundamental gain models, as measurements are difficult (Shtengel et al. 1998). However, the lack of

Dalton [eds.], *Introduction to Organic Electronic and Optoelectronic Materials and Devices*, Boca Raton, FL: CRC Press, 2008.)

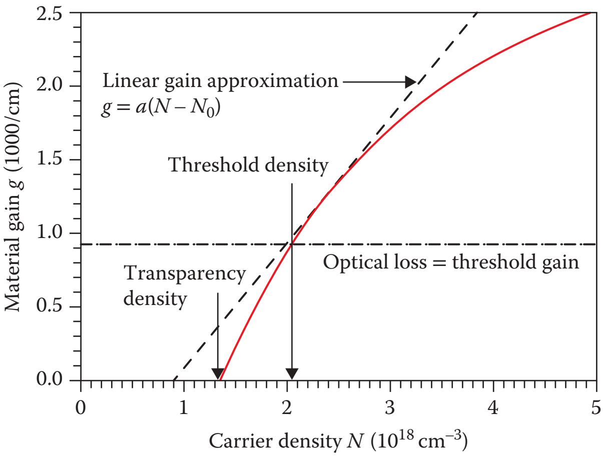

FIGURE 26.4 Optical gain provided by the active layer material as function of the carrier density.

experimental validation of the gain model creates a major uncertainty in any laser simulation. The analysis of laser measurements typically only delivers the relationship $g_m(j) = G_o \ln(j/j_{tr})$ between the modal gain $g_m = \Gamma_a g$ and the current density j, with G_o and the transparency current density j_{tr} as fit parameters (see Chapter 27). The optical confinement factor Γ_a gives the overlap of the active layer and the lasing mode, which is usually extracted from waveguide simulations (see Chapter 4).

Figure 26.4 indicates optical losses that are caused by photon emission from the laser as well as by the internal absorption and photon scattering. For the simple Fabry–Pérot (FP) laser structure shown in Figure 26.3, the optical loss at the two cavity mirrors is given by

$$\alpha_m = \frac{1}{2L} \ln\left(\frac{1}{R_f R_b}\right) \tag{26.2}$$

with the cavity length L and the reflectances R_f and R_b of front and back mirrors, respectively. The internal optical loss α_i can be extracted from laser measurements (see Chapter 27) but the microscopic mechanisms causing this loss are often hard to identify. They are typically approximated as

$$\alpha_i = \alpha_b + \sum_i \Gamma_i \left(k_{n,i} n + k_{p,i} p\right) \tag{26.3}$$

with the background loss α_b (e.g., due to photon scattering) and the sum over all free-carrier-related loss in any individual layer i of the laser structure (where k is a free-carrier absorption parameter). The confinement factor Γ_i is the ratio of the layer volume to the volume of the optical lasing mode. Photon absorption by free carriers depends on the energy band structure of the conduction and valence bands. It is typically stronger for holes due to intervalence band absorption (Piprek et al. 2000).

To reach the lasing threshold, the optical gain must compensate for the internal optical loss (α_i) and for photon emission from the device (α_m). Both loss parameters apply to the whole lasing mode so that the threshold gain g_{th} is defined by

$$\Gamma_a g_{th}\left(N_{th}\right) = \alpha_m + \alpha_i \tag{26.4}$$

with the active layer confinement factor Γ_a and the threshold carrier density N_{th} (see Figure 26.4).

26.3 Threshold Current and Slope Efficiency

The threshold current I_{th} provides the threshold carrier density N_{th} and compensates for various carrier loss mechanisms, some of which are illustrated in Figure 26.1. A spontaneous electron–hole recombination is needed to provide initial photons for stimulated recombination (lasing), but most spontaneously emitted photons are lost. In a common analytical approach, the spontaneous emission rate $R_{spon} = BN^2$ is proportional to the square of the carrier density. Nonradiative recombination mechanisms are either defect-related Shockley–Read–Hall (SRH) recombinations ($R_{SRH} = AN$) or Auger recombinations ($R_{Aug} = CN^3$). The former transfers the recombination energy to lattice vibrations (phonons) and the latter to other free carriers. This simple but very popular ABC recombination model leads to the threshold current

$$I_{th} = \frac{eV_a}{\eta_a} R_{ABC}(N_{th}) = \frac{eV_a}{\eta_a}\left(AN_{th} + BN_{th}^2 + CN_{th}^3\right) = I_{SRH} + I_{spon} + I_{Aug} + I_{leak} \tag{26.5}$$

with the injection efficiency η_a giving the fraction of electrons that recombines within the active layer of volume V_a, thereby accounting for carriers that recombine outside the active layer, e.g., due to electron leakage (see Figure 26.2). Leakage can occur by various mechanisms (Piprek et al. 2000). It is hard to asses

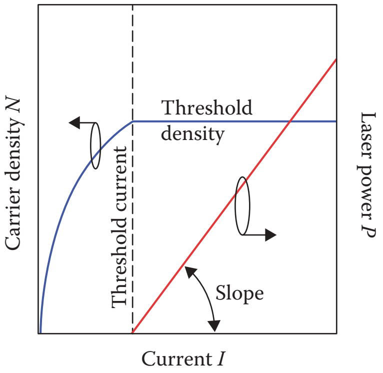

FIGURE 26.5 Illustration of carrier density and lasing power as function of the injected current without self-heating.

with analytical models and typically requires full solutions of the semiconductor transport equations (see Chapter 2). Simpler models often neglect leakage or use a fictitious parameter η_a.

With a stronger current injection $I > I_{th}$, the carrier density remains constant at N_{th} as additional electron–hole pairs are consumed by stimulated recombination (Figure 26.5). The stimulated recombination rate is $R_{stim} = v_g g S$ (where v_g is photon group velocity). Under ideal conditions without self-heating, the laser power rises proportional to $I_{stim} = I - I_{th}$ as

$$P = \eta_d \frac{h\nu}{e}\left(I - I_{th}\right) = \eta_i \frac{\alpha_m}{\alpha_m + \alpha_i} \frac{h\nu}{e}\left(I - I_{th}\right) \tag{26.6}$$

with the photon energy $h\nu$. Note that P gives the total emission from both facets. The differential quantum efficiency η_d is the fraction of carriers injected above threshold that contributes photons to the laser beams. It can be separated into internal differential efficiency η_i and optical efficiency η_{opt}. The latter is equal to $\alpha_m(\alpha_m + \alpha_i)^{-1}$ and gives the fraction of stimulated photons that leaves the laser. The internal differential efficiency η_i is often close to unity above threshold as there are no further recombination losses with constant carrier density N_{th} in the active layer. However, the leakage current may rise above the threshold, especially at higher temperatures (Piprek et al. 2000).

26.4 Temperature Effects

The current flow through the laser diode as well as nonradiative recombination processes generate heat inside the laser and elevate the internal temperature distribution $T(x, y, z)$. This temperature rise more or less affects all material parameters. One of the most fundamental changes occurs with the semiconductor bandgap $E_g(T)$, which is commonly modeled by the Varshni formula

$$E_g(T) = E_g(0) - \frac{AT^2}{B + T} \tag{26.7}$$

using the phenomenological parameters A and B (Piprek 2003). As the band gap shrinks, the lasing wavelength increases (redshifts). In addition, the Fermi distribution of carriers inside the energy bands broadens with higher temperature. Both these effects change the gain spectrum. Figure 26.6 illustrates this change for a fixed carrier density. The gain peak determines the emission wavelength of FP lasers, and it redshifts with higher temperature. But the gain peak also declines, so that more carriers are needed to maintain the lasing threshold (cf. Figure 26.4). Consequently, the threshold current rises with higher temperature, which is often described by the characteristic temperature $T_0 = (T_2 - T_1)/\ln(I_2/I_1)$ that can be extracted

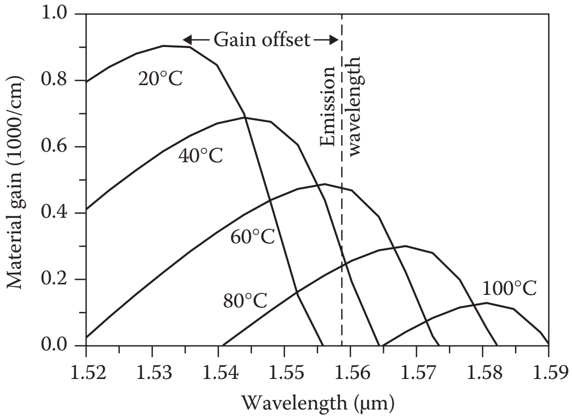

FIGURE 26.6 Optical gain spectrum shift with increasing temperature and constant carrier density.

from measurements of $I_{\mathrm{th}}(T)$. The decline of the slope efficiency is calculated in a similar way. These phenomenological parameters are useful in characterizing the temperature sensitivity of a given laser diode (see Chapter 27). However, they don't reveal the physical mechanism behind temperature effects and are not suitable for predictive simulations. For instance, if the lasing wavelength is fixed by the optical cavity design, the impact of the gain shift very much depends on the initial difference between emission wavelength and gain peak wavelength (gain offset). An example is illustrated in Figure 26.6 (Piprek et al. 1998). Here, the rising temperature first increases the gain available at the emission wavelength. The threshold current initially declines and reaches a minimum near 60°C when the gain offset is zero. With further heating, the threshold current rises rapidly. Thus, T_0 depends on the temperature in this case and fails even as a descriptive parameter.

More advanced laser models don't employ fit parameters such as T_0 and describe the underlying physical mechanisms instead, starting with the shift of the gain spectrum (Piprek et al. 2000). An increasing carrier density in the active layer goes hand in hand with increasing carrier losses. For instance, the Auger recombination rate is not affected only by the increasing carrier density, but also by the temperature sensitivity of the Auger process, which depends on its activation energy E_a: $C(T) \propto \exp(-E_a/kT)$. Carrier leakage is also sensitive to temperature changes, and it may raise the threshold current and reduce the slope efficiency. The slope efficiency also depends on the free-carrier absorption, which increases with the carrier density. All these interdependencies require advanced numerical laser models for a more reliable analysis of the temperature sensitivity (see Chapter 27).

26.5 Efficiency Analysis

As an illustrative example for this section, Figure 26.7 shows the simulated power–current and bias–current characteristics of a GaN-based laser diode in continuous-wave (CW) operation (Piprek 2016). Self-heating apparently causes a decline of the slope efficiency, which limits the maximum power achievable. Another key performance parameter is the power conversion efficiency η_{PCE}. It is defined as the ratio of light output power P to electrical input power IV (where V is bias). It can be separated into electrical efficiency $\eta_{\mathrm{ele}} = h\nu/eV$ and external quantum efficiency η_{EQE}. The latter is the ratio of emitted photon number to injected number of electron–hole pairs. Equation 26.6 leads to the following power conversion efficiency formula:

$$\eta_{\mathrm{PCE}}(I) = \frac{h\nu}{eV}\eta_{\mathrm{i}}\frac{\alpha_{\mathrm{m}}}{\alpha_{\mathrm{m}}+\alpha_{\mathrm{i}}}\frac{I-I_{\mathrm{th}}}{I} = \eta_{\mathrm{ele}}\eta_{\mathrm{EQE}} = \eta_{\mathrm{ele}}\eta_{\mathrm{s}}\eta_{\mathrm{th}} \tag{26.8}$$

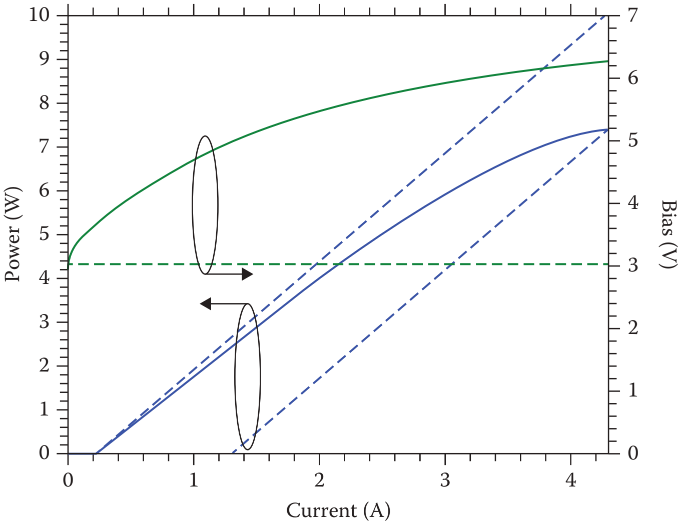

FIGURE 26.7 Lasing power and bias versus current. The dashed bias line indicates the photon energy. The dashed power lines indicate the change in threshold current for constant slope efficiency.

including the unitless slope efficiency η_s and the threshold current efficiency $\eta_{th} = (I - I_{th})/I$. Note that η_s is different from the differential slope efficiency dP/dI and from the averaged slope efficiency $P/(I - I_{th})$, which are both given in W/A and not used here. However, this popular analytical model is somewhat ambiguous when the laser experiences relevant self-heating, which causes a sublinear $P(I)$ characteristic as shown in Figure 26.7. Most parameters in Equation 26.8 change as the internal laser temperature rises with increasing current. The threshold current rises together with the threshold carrier density due to declining material gain. The slope efficiency declines due to increasing carrier leakage and/or rising internal absorption.

Figure 26.8 illustrates these efficiencies as simulated for an InGaN/GaN laser diode (Piprek 2016). At low current, η_{PCE} is mainly limited by the threshold current efficiency (which is zero for $I < I_{th}$). At high current, the strongest efficiency limitation is caused by the decline of the electrical efficiency due to the increasing excess bias above the minimum required bias $h\nu/e$ (dashed bias line shown in Figure 26.7). This excess bias is relatively high in GaN-based lasers, partially due to the low hole conductivity. However, the influence of slope efficiency and threshold efficiency depends on the assumption made in the analysis. The assumption of a constant, temperature-insensitive threshold current leads to the solid curves shown in Figure 26.8, so that temperature effects are mainly reflected by the slope efficiency. This is a convenient and common approach to extract efficiency plots directly from the measured *PI* and *VI* characteristics, without any simulation (Crump et al. 2013). However, with strong self-heating, the dependence on $I_{th}(T)$ needs to be considered, which is hard to extract directly from experimental results. Numerical simulations are indicated by the dashed lines in Figure 26.8, which reveal that the threshold efficiency is more temperature sensitive than the slope efficiency (Piprek 2016). For constant, temperature-insensitive slope efficiency, an approximate method of extracting $I_{th}(I)$ directly from measurements is illustrated by the dashed power lines shown in Figure 26.7. Starting with the measured slope dP/dI at threshold, the dashed line is shifted parallel to the current axis so that each power $P(I)$ is connected to a threshold current $I_{th}(I)$.

26.6 Rate Equation Analysis

Time-dependent effects are often analyzed in terms of rate equations considering all physical processes that change the densities of photons and carriers. We here discuss a set of two rate equations for the

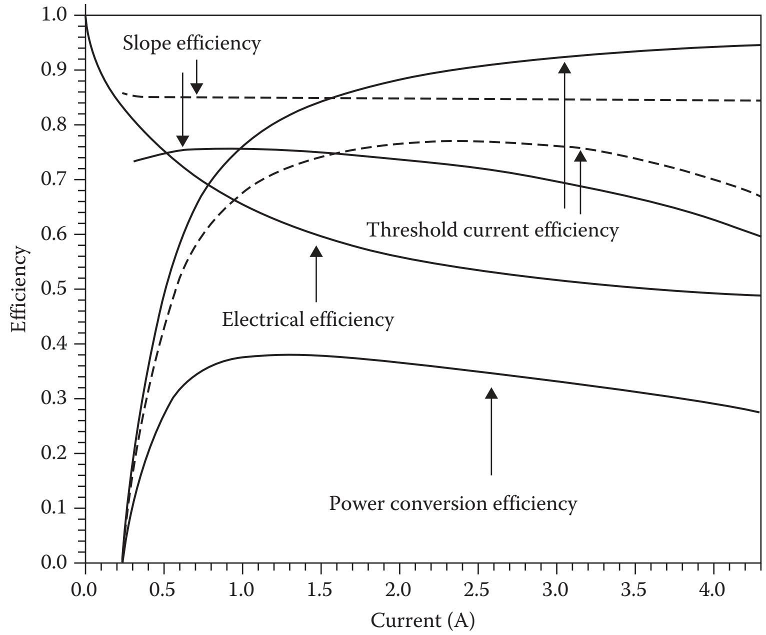

FIGURE 26.8 Changes in efficiency with increasing injection current. The solid lines indicate constant threshold current and the dashed lines indicate constant slope efficiency.

single-mode photon density S averaged over the modal volume V_m and the carrier density N averaged over the active volume V_a:

$$\frac{dN}{dt} = \frac{\eta_a I}{eV_a} - \left[AN + BN^2 + CN^3\right] - v_g g(N, S)\,S \tag{26.9}$$

$$\frac{dS}{dt} = \Gamma_a v_g g(N, S)\,S + \beta\Gamma_a BN^2 - v_g\left[\alpha_i + \alpha_m\right] S \tag{26.10}$$

The active layer carrier density $N(t)$ in Equation 26.9 is increased by current injection (first term, including the injection efficiency η_a) and is reduced by all four recombination processes (see Figure 26.1) that limit the carrier lifetime. The photon density $S(t)$ in Equation 26.10 is increased by stimulated emission (first term) and by the small fraction β of spontaneously emitted photons that enters the lasing mode (second term). $S(t)$ is reduced by photon emission and internal photon losses (third term in Equation 26.10), which limit the photon lifetime τ_p defined by $\tau_p^{-1} = v_g(\alpha_i + \alpha_m)$. The dynamic response of both densities can be understood from these rate equations. For instance, when $N(t)$ increases, $S(t)$ increases due to the rising gain $g(N)$. But that decreases the carrier density according to the last term in Equation 26.9. $N(t)$ is also reduced by ABC recombination. Consequently, the photon density $S(t)$ drops again, also due to photon losses. Thus, the dynamic behavior of both densities is strongly influenced by loss mechanisms.

However, this approach neglects the nonuniform distribution of carriers and photons (Carroll et al. 1998). A nonuniform distribution of photons can result in spatial hole burning into the carrier distribution in regions with high photon density, reduce the gain, and increase the refractive index (see Chapter 27). Multiple optical modes would require multiple rate equations for calculating each photon density (Petermann 1988). Lateral diffusion of carriers out of the active layer is partially considered by the injection efficiency η_a and is often minimized by lateral carrier confinement.

Under steady-state conditions ($dS/dt = 0$) with vanishing β, Equation 26.10 gives the relation $\Gamma_a g(N, S) = \alpha_i(N) + \alpha_m$ describing the balance of gain and losses required for lasing (see Figure 26.4).

The first equation $\mathrm{d}N/\mathrm{d}t = 0$ then yields the steady-state photon density $S_o = \eta_i \tau_p (I - I_{th})(eV_m)^{-1}$. The steady-state optical power emitted through both mirrors is given by $P_o = v_g \alpha_m h\nu V_m S_o$ in agreement with Equation 26.6.

With analog modulation, sinusoidal variations are added to the steady-state input current I_o. In the simple case of just one angular frequency $\omega = 2\pi f$ and constant amplitude ΔI, the injection current in Equation 26.9 becomes $I(t) = I_o + \Delta I \times \sin(\omega t)$. If the period of the modulation is much larger than any time constant, the output power still follows the steady-state solution (Equation 26.6). But in the general dynamic case, analytical solutions of the rate equations cannot be found and numerical methods need to be applied.

Current modulations ΔI well below $(I_o - I_{th})$ lead to variations ΔN, ΔS, and ΔP, which are much smaller than the steady-state values N_{th}, S_o, and P_o, respectively. This small signal case allows the rate equations to be solved analytically (Coldren and Corzine 1995) using the linear gain approximation illustrated in Figure 26.4. Assuming $\beta = 0$, the small signal solution to the rate equations is

$$\Delta P(\omega) = M(\omega) \times \Delta P = \frac{\omega_r^2}{\omega_r^2 - \omega^2 + i\omega\gamma} \times \eta_i \frac{\alpha_m}{\alpha_i + \alpha_m} \frac{h\nu}{e} \Delta I \tag{26.11}$$

with the angular electron–photon resonance frequency $\omega_r = 2\pi f_r$ given by

$$\omega_r^2 = \frac{a v_g S_o}{\tau_p \left(1 + \varepsilon S_o\right)} \left(1 + \frac{\varepsilon}{v_g a \tau_c}\right) \tag{26.12}$$

including the photon lifetime τ_p and the gain compression factor ε from Equation 26.1. At low photon densities ($\varepsilon = 0$), Equation 26.12 is reduced to $\omega_r^2 = (\tau_{st}\tau_p)^{-1}$ with the differential stimulated emission time $\tau_{st} = \mathrm{d}R_{stim}/\mathrm{d}N = (a v_g S_o)^{-1}$. The damping constant is given by $\gamma = \tau_{st}^{-1} + \tau_c^{-1}$ including the differential carrier lifetime τ_c, with $\tau_c^{-1} = \mathrm{d}R_{ABC}/\mathrm{d}N = A + 2BN_{th} + 3CN_{th}^2$.

Figure 26.9 illustrates the normalized modulation response $|M(\omega)|$ as a function of modulation frequency for different gain compression factors ε (Piprek and Bowers 2002). At low frequencies, the photon

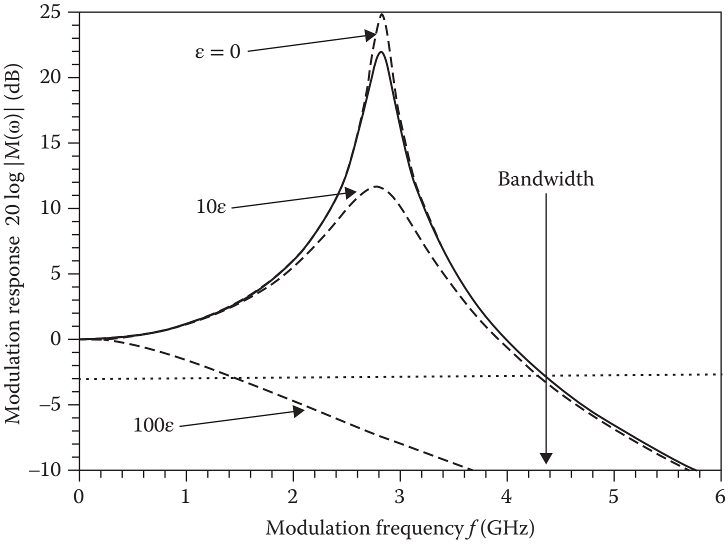

FIGURE 26.9 Modulation response versus modulation frequency. The dashed lines show the effect of changing the gain suppression factor ε.

density can easily follow the current modulation and the response function is quite flat. The response is most intense near the resonance frequency ω_r. The peak frequency is given by $\omega_p^2 = \omega_r^2 - \gamma^2/2$. At even faster current modulation, the photons cannot follow any more and the response function declines. The modulation bandwidth f_b is the frequency at which the response drops to $|M(2\pi f_b)| = 2^{-1/2} = -3dB$ (see Figure 26.9). The bandwidth rises with the steady-state current but saturates at high currents due to increased damping, device heating, gain compression, transport effects, or parasitics (Kjebon et al. 1996).

26.7 Basic Laser Cavity Designs

Chapters 27 through 34 feature specific laser designs and applications in much more detail, we here only give a brief overview of the main types of optical resonators. The most simple cavity design uses the reflection at the two laser facets for optical feedback (FP laser, see Figures 26.3 and 26.10, and Chapter 27). Constructive interference of forward and backward traveling optical waves is restricted to specific wavelengths. Those wavelengths constitute the longitudinal mode spectrum of the laser. The cavity length is typically on the order of several hundred microns, much larger than the lasing wavelength, so that many longitudinal modes may exist. The actual lasing modes are those receiving strong optical gain. Single-mode lasing is hard to achieve in simple FP structures, especially under modulation. Dynamic single-mode operation is required in many applications and is achieved using optical cavities with selective reflection. The distributed feedback (DFB) laser is widely used in single-mode fiber optic applications (Figure 26.10). Typical DFB lasers exhibit a periodic longitudinal variation of the refractive index within one layer of the edge-emitting waveguide structure. This index variation provides continuous (distributed) reflection at a wavelength given by the variation period. Facet reflection is not needed in DFB lasers; however, facet coating may be used to increase the light emission from one end of the cavity. Other laser resonators terminate the optical cavity by two distributed Bragg reflectors (DBRs) with a stepwise alternating index. More details on DFB and DBR lasers are given in Chapters 30 and 31.

A special type of DBR laser is the vertical-cavity surface-emitting laser (VCSEL) which emits light through the bottom and/or top surface of the layered structure (see Figure 26.10 and Chapters 34 and 45). The light travels perpendicular to the active layer and receives optical gain only over a very short travel distance. Thus, many more photon roundtrips and highly reflective VCSEL mirrors with more than 99% reflectivity are needed for lasing.

In transversal directions, the optical wave is typically confined by the refractive index profile, using a ridge (DFB laser) or a pillar (VCSEL) to form the waveguide. Even with restriction to one longitudinal mode, multiple transversal optical modes may occur in all three types of lasers.

27.1 Introduction

High-power diode lasers deliver the energy to all high-performance laser systems, either as a pump source or as a source for direct material processing. Comprehensive descriptions of their manufacturing and applications can be found in, for example, References [1–4].

The lasers are constructed like all edge-emitting diode lasers as shown in Figure 27.1. The layer structure grown by metal-organic vapor phase epitaxy (MOVPE) or molecular beam epitaxy (MBE) on a crystalline substrate (e.g., GaAs, InP, GaN) consists basically of n-doped cladding and optical confinement layers, an active region (typically a single quantum well [QW]) and p-doped optical confinement and cladding layers and is completed by a highly p-doped cap (contact) layer. However, there are three peculiarities compared to other lasers: first, the vertical waveguide is weak (large total thickness of confinement layers or small index step between confinement and cladding lasers). Second, the emitting aperture is very broad, ranging from tens to hundreds of micrometers, which results in a nonstationary behavior [5,6]. Third, the cavity between the cleaved facets is very long, reaching values of several millimeters and the two facets are extremely differently coated.

The lateral optical and current confinement can be achieved by several means. In the most simple case, there is no built-in waveguide at all so that the optical field is confined to the region below the contact

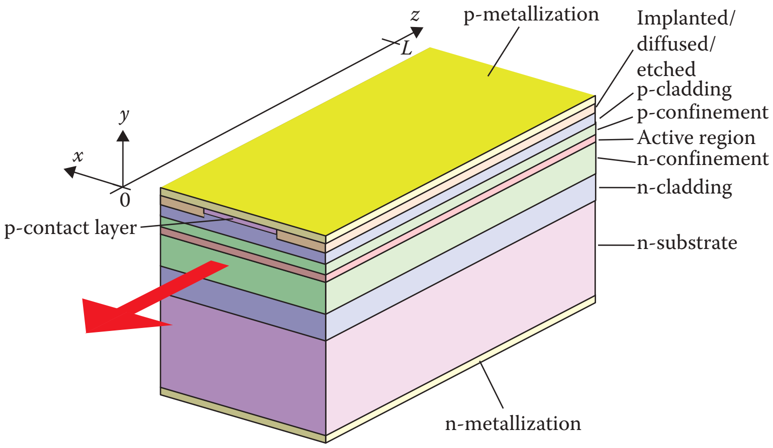

FIGURE 27.1 Schematic view of a high-power broad-area semiconductor laser.

stripe by gain guiding at low power and under pulsed operation, but is strongly influenced by the thermally induced waveguide created under continuous-wave (CW) operation at high power. In order to restrict the current spreading, the electrical conductivity of parts of the p-doped region besides the contact stripe can be reduced by ion implantation, impurity diffusion, or by implementation of a reverse-biased p-n junction. If the semiconductor besides the p-contact is etched away up to a defined depth and subsequently filled with an insulator, the index contrast between the semiconductor below the contact stripe and the insulator results in a lateral built-in index guide, which stabilizes the optical field at low power and under pulsed operation, but increases the far-field divergence.

The cleaved facets located at $z = 0$ and $z = L$ in Figure 27.1 are low reflection coated on the front side ($R_0 \propto 0.01$) and high reflection coated on the rear side ($R_L > 0.9$). If a small optical spectrum and a reduced drift of the wavelength with temperature and injection current are required, Bragg gratings could be implemented into the cavity, resulting in distributed feedback (DFB) or distributed Bragg-reflection (DBR) lasers [7]. However, here we focus on the Fabry–Pérot (FP) type of high-power lasers where the coated facets provide the feedback.

The simulation of broad-area lasers is challenging because of the different temporal and spatial scales involved. The timescales for the variations of the optical field, the carrier densities, and the temperature are ps, ns, and μs, respectively. The spatial scales range from nanometers (active QW) and micrometers (epitaxial layers and lateral waveguides) up to millimeters (cavity). Another difficulty arises from the highly nonlinear behavior because of the coupling of the optical, electronic, and thermal phenomena. Therefore, until now, no simulation tool covering all spatiotemporal scales and physical phenomena has been available. In this chapter, we survey models with different complexity for the simulation of high-power lasers [6].

This chapter is organized as follows. In Section 27.2, we present a model for high-power lasers based on measurable parameters, which can be used to compare different laser structures and to predict the electro-optical characteristics as a function of cavity length and facet reflectivities, for example. In Section 27.3, we investigate the profile of the optical power in the cavity in more detail and derive some of the equations used in Section 27.2. Furthermore, we discuss several effects responsible for the saturation of the output power with increasing injection current. The parabolic paraxial wave equation based on the slowly varying amplitude and rotating wave approximations, taking into account gain dispersion, spontaneous emission, and a third-order nonlinear susceptibility, is derived in Section 27.4. A balance equation for the electromagnetic energy density will be given. In Section 27.5, we present the equations that can be used to calculate the nonlinear lateral optical modes of broad-area lasers and discuss several root causes for the multipeaked and not diffraction-limited lateral field profile of broad-area lasers. Finally, in Section 27.6, we summarize a thermodynamic-based model for the transport of the charged carriers and the temperature flow. Particular attention is paid to a consistent formulation with the model for the optical field presented in Section 27.4.

27.2 Phenomenological Model

In this section, a model for high-power lasers based on measurable parameters is presented. The model can be used to compare different laser structures and to predict the electro-optical characteristics in dependence on cavity length and facet reflectivities, for example.

27.2.1 Summary of the Governing Equations

The total output power P_{out} of a semiconductor laser in dependence on the injection current I is given by

$$P_{\text{out}} = \frac{\hbar\omega}{e}\eta_{\text{ext}}\left(I - I_{\text{thr}}\right) \tag{27.1}$$

where η_{ext} is the external differential efficiency, I_{thr} the threshold current, ω the angular lasing frequency, $\hbar$ the reduced Planck constant, and e the elementary charge. Here and in what follows $I \geq I_{\text{thr}}$ is assumed. The photon energy $\hbar\omega$ can be written as (c vacuum speed of light, h Planck constant)

$$\hbar\omega = \frac{hc}{\lambda} \tag{27.2}$$

where the vacuum lasing wavelength λ is assumed to vary linearly with the temperature T in the cavity as

$$\lambda = \lambda_{\text{ref}} + \frac{\mathrm{d}\lambda}{\mathrm{d}T}\Delta T \qquad \text{with} \qquad \Delta T = T - T_{\text{ref}} \tag{27.3}$$

with T_{ref} being the reference (heat sink or ambient) temperature. The output powers P_0 at the left ($z = 0$) facet and P_L at the right ($z = L$) facet with intensity reflection coefficients R_0 and R_L, respectively, are obtained from the total power as

$$P_0 = \frac{P_{\text{out}}}{1 + (1 - R_L)(1 - R_0)^{-1}\sqrt{R_0 R_L^{-1}}} \quad \text{and} \quad P_L = \frac{P_{\text{out}}}{1 + (1 - R_0)(1 - R_L)^{-1}\sqrt{R_L R_0^{-1}}} \tag{27.4}$$

(cf. Equation 27.40).

To calculate the threshold current, a model for the modal gain is required. First one should be aware that the gain depends on both the wavelength and the current density. For a fixed wavelength λ, the dependence of the modal gain of QW lasers on the current density can be well approximated by a logarithmic relation,

$$g_{\text{m}} = G_0 \ln \frac{j}{j_{\text{tr}}} \tag{27.5}$$

where G_0 is the gain prefactor (proportional to the differential gain) and j_{tr} the transparency current density. At $j = j_{\text{tr}}$ the gain vanishes, i.e., a wave with the wavelength λ propagating along the QW embedded in a nonabsorbing medium is neither absorbed nor amplified (transparency). Due to the fact that FP lasers lase at the maximum of the gain spectrum, we need the dependence of the peak gain on the current density for which the relation Equation 27.5 can be used, too. However, one must keep in mind that the peak gain never becomes negative, but approaches zero for vanishing current. Therefore, $j \gg j_{\text{tr}}$ must be observed and the transparency current density obtained by the analysis of the length dependencies of external differential efficiency and threshold current as described in Section 27.2.2 has no direct physical interpretation. One should mention that of course any other functional dependence $g_{\text{m}}(j)$ that can be solved analytically for j, such as a linear one, could be used. However, then the procedure presented in Section 27.2.2 would yield differing parameters G_0 and j_{tr}.

Assuming the logarithmic dependence of the modal gain on the current density and an exponential dependence of the threshold current on the temperature, the threshold current can thus be written as

$$I_{\mathrm{thr}} = WLj_{\mathrm{tr}}e^{\frac{g_{\mathrm{thr}}}{G_0}}e^{\frac{\Delta T}{T_0}} \tag{27.6}$$

where W is the contact width, L the contact length (assumed equal to the cavity length), and T_0 the characteristic temperature of the threshold current. Similarly, the external differential efficiency can be written as (cf. Equation 27.44)

$$\eta_{\mathrm{ext}} = \frac{\alpha_{\mathrm{out}}}{g_{\mathrm{thr}}}\eta_{\mathrm{i}}e^{-\frac{\Delta T}{T_1}} \tag{27.7}$$

where T_1 is the characteristic temperature of the external differential efficiency. The internal efficiency η_{i} gives the fraction of the total current increment that results in stimulated emission of photons. It describes the effect that not all electron–hole pairs *additionally* injected above threshold are converted into photons by stimulated emission. The threshold gain g_{thr} is

$$g_{\mathrm{thr}} = \alpha_{\mathrm{out}} + \alpha_{\mathrm{i}} \tag{27.8}$$

with the internal losses α_{i} and the outcoupling (mirror) losses

$$\alpha_{\mathrm{out}} = -\frac{1}{2L}\ln(R_0R_L) \tag{27.9}$$

Finally, the temperature rise can be calculated from the dissipated power Q and the thermal resistance r_{th} related to the contact area,

$$\Delta T = \frac{r_{\mathrm{th}}}{WL}Q \tag{27.10}$$

The dissipated power is given by the difference between electrical input power and optical output power,

$$Q = UI - P_{\mathrm{out}} \tag{27.11}$$

with the voltage–current characteristics

$$U = \Delta U + \frac{\hbar\omega}{e} + \frac{r_{\mathrm{s}}}{WL}I \tag{27.12}$$

where ΔU is the so-called defect voltage and r_{s} the series resistance related to the contact area. The main contribution to the defect voltage arises from the spacing of the quasi-Fermi potentials of electrons and holes in the active region (Fermi voltage), which is assumed to be clamped above threshold and is always larger than the photon energy divided by the elementary charge. The last term in Equation 27.12 is due to the Ohmic voltage drop in the bulk semiconductor layers, at the heteroboundaries, and at the semiconductor–metal junctions.

Instead of Equation 27.11 sometimes other expressions are reported. For example, by inserting Equations 27.1 and 27.12 into Equation 27.11 and rearranging the terms,

$$Q = \frac{\hbar\omega}{e}I_{\mathrm{thr}} + \frac{\hbar\omega}{e}(1-\eta_{\mathrm{i}}e^{-\frac{\Delta T}{T_1}})(I-I_{\mathrm{thr}}) + \frac{\hbar\omega}{e}(\eta_{\mathrm{i}}e^{-\frac{\Delta T}{T_1}} - \eta_{\mathrm{ext}})(I-I_{\mathrm{thr}}) + \Delta UI + \frac{r_{\mathrm{s}}}{WL}I^2 \tag{27.13}$$

is obtained. The third term can be also written as

$$\frac{\hbar\omega}{e}(\eta_i e^{-\frac{\Delta T}{T_1}} - \eta_{\text{ext}})(I - I_{\text{thr}}) = \alpha_i L\bar{P} \tag{27.14}$$

where we have used Equations 27.7, 27.8, and 27.43. The averaged internal power $\bar{P}$ is defined in Equation 27.32. The dissipated power is thus the sum of the heat generated at threshold by nonradiative and spontaneous recombination (first term in Equation 27.13), the heat generated above the threshold due to additional nonstimulated recombination and carrier leakage (second term), the heat generated by absorption (third term), the heat caused by the defect voltage (fourth term), and the Joule heat (last term). It is worth to mention that in Equations 27.11 and 27.13, it is assumed that the spontaneously emitted radiation is completely absorbed in the cavity so that P_{out} contains only the stimulated emission.

All equations have been written in such a manner that the geometrical scaling given by W and L is explicitly separated. Note, however, that the dependence of r_{th} on W cannot be neglected because the thermal resistance $R_{\text{th}} = r_{\text{th}}/(WL)$ is not inverse proportional to W. For example, for a rectangular-shaped infinitely thin heat source,

$$r_{\text{th, 2D}} \approx \frac{W}{\kappa\pi} \ln\left(\frac{4h}{W}\right) \tag{27.15}$$

holds under the condition $W \ll h < W_s$, where κ is the thermal conductivity of the material with thickness h and width $2W_s$ separating the heat source of width W from the heat sink [8]. Only for a purely one-dimensional heat flow

$$r_{\text{th, 1D}} = \frac{h}{\kappa} \tag{27.16}$$

is independent of W.

For shallow-edged samples with substantial lateral current spreading, the transparency current density obtained by the procedure presented in Section 27.2.2 depends on the p-contact width, too [9]. In order to determine the transparency current density for an infinite p-contact width $j_{\text{tr},W\to\infty}$ without current spreading, the transparency *current* has to be plotted and linearly fitted in dependence on W. From the slope $\mathrm{d}I_{\text{tr}}/\mathrm{d}W$ one obtains $j_{\text{tr},W\to\infty}$ and from the extrapolation $W \to 0$ the spreading current $I_{\text{tr, spread}}$ according to the relation [9]

$$I_{\text{tr}}(W) = j_{\text{tr},W\to\infty}LW + I_{\text{tr, spread}} \tag{27.17}$$

The basic assumption underlying Equation 27.17 is that $I_{\text{tr, spread}}$ is independent of W. If different cavity lengths are considered, Equation 27.17 has to be divided by L.

For a numerical calculation of the electro-optical characteristics, Equation 27.10 is best suited because $\Delta T(I)$ is a monotonous function (in contrast to $P(I)$). Knowing ΔT, the threshold current and external efficiency can be determined from Equations 27.6 and 27.7, respectively, and finally the output power from Equation 27.1.

27.2.2 Determination of the Parameters Entering the Model

In what follows we consider an asymmetric super-large optical-cavity structure published in Reference [10]. The parameters η_i, α_i, G_0, and j_{tr} are determined by measuring the power–current characteristics of as-cleaved lasers having different cavity lengths L, operated under pulsed conditions to avoid self-heating ($\Delta T = 0$). Thus pulse lengths below 1 μs and duty cycles below 1% are required. Note that the lasing wavelength could substantially vary with L, which must be taken into account in the calculation of the optical power from the measured photovoltage of the detector by adjusting the calibration factor. The measured *P–I* characteristics have to be linearly fitted to extract the slope efficiencies and threshold currents for the different cavity lengths.

If the inverse external differential efficiency is plotted versus cavity length (cf. Figure 27.2a),

$$\eta_{\mathrm{ext}}^{-1}(L) = \eta_{\mathrm{i}}^{-1}\left(1 - \frac{\alpha_{\mathrm{i}}}{\ln(R)}L\right) \tag{27.18}$$

a linear fit delivers $-\eta_{\mathrm{i}}^{-1}\alpha_{\mathrm{i}}/\ln(R)$ from the slope $\eta_{\mathrm{ext}}^{-1}(L)$ and η_{i}^{-1} from the extrapolation of η_{ext}^{-1} to $L \rightarrow 0$. A linear fit of the logarithm of the threshold current density versus the inverse cavity length

$$\ln(j_{\mathrm{thr}})(L^{-1}) = \ln(j_{\mathrm{tr}}) + G_0^{-1}\left(\alpha_{\mathrm{i}} - \ln(R)L^{-1}\right) \tag{27.19}$$

as shown in Figure 27.2b yields $-G_0^{-1}\ln(R)$ from the slope $\ln(j_{\mathrm{thr}})(L^{-1})$ and the threshold current density for an infinite cavity length $\ln(j_{\mathrm{thr},\infty}) = \ln(j_{\mathrm{tr}}) + G_0^{-1}\alpha_{\mathrm{i}}$ from the extrapolation of $\ln(j_{\mathrm{thr}})$ to $L^{-1} \rightarrow 0$. The results of this procedure are contained in Table 27.1, where facet reflectivities $R_0 = R_L = 0.3$ have been assumed in the evaluation. For other cases they must be correspondingly chosen.

The cavity lengths L have to be carefully chosen to ensure linear dependencies $\eta_{\mathrm{ext}}^{-1}(L)$ and $\ln(j_{\mathrm{thr}})(L^{-1})$. If L is too small (large threshold gain), η_{ext}^{-1} could increase with decreasing L due to an increase of α_{i} (enhanced free-carrier absorption) and a decrease of η_{i} (enhanced carrier leakage). If L is too large (small threshold gain), the threshold gain does not depend logarithmically on the threshold current density because $j_{\mathrm{th}} \rightarrow j_{\mathrm{tr}}$ so that the model fails, too.

The characteristic temperatures should be determined by measuring the power–current characteristics at different chip temperatures under pulsed conditions. The outcoupling losses (determined by cavity length and facet reflectivities) of the laser under investigation should coincide, nearly, with the intended values for CW operation, because T_0 and T_1 decrease with increasing threshold gain. The temperature range must be correspondingly chosen, too, because T_0 and T_1 decrease with increasing temperature. The results of the measurements and the linear fits of the logarithms of the threshold current density and external

differential efficiency versus temperature rise,

$$\ln\left(\frac{j_{thr}(T)}{j_{thr}(T_{ref})}\right) = \frac{\Delta T}{T_0} \quad \text{and} \quad -\ln\left(\frac{\eta_{ext}(T)}{\eta_{ext}(T_{ref})}\right) = \frac{\Delta T}{T_1} \tag{27.20}$$

are shown in Figure 27.3a and 27.3b.

The series resistance and defect voltage are obtained from a fit of the linear part of the voltage–current characteristics above threshold:

$$U = U_0 + \frac{r_s}{WL} I \qquad \text{and} \qquad \Delta U = U_0 - \frac{hc}{e\lambda_{\text{ref}}} \tag{27.21}$$

The result is shown in Figure 27.4a. The voltage must be measured with care to ensure that the true series resistance of the chip is obtained. Typically a so-called four-terminal or 4-wire sensing separating the current and voltage electrodes has to be applied. Finally, the thermal resistance can be determined from a linear fit of the lasing wavelength versus the dissipated power,

$$\lambda(Q) = \lambda_{\text{ref}} + \frac{\mathrm{d}\lambda}{\mathrm{d}T} \frac{r_{\text{th}}}{WL} Q, \tag{27.22}$$

where Q is calculated according to Equation 27.11

There are two possibilities to employ Equation 27.22. The first possibility is based on the measurement of the center wavelength λ_{center} of the emission spectrum above threshold versus injection current. This yields a correct result, if a sufficiently large number of modes is lasing and the envelope of the spectrum exhibits a Gaussian-like shape. The shift of λ_{center} is mainly determined by the temperature dependence of the energy gap of the active region, but sometimes also by the temperature dependence of the confinement factor or screening of polarization fields in GaN-based lasers, for example. The method has the advantage, that the requirement on the spectral resolution of the optical spectrometer is modest. A disadvantage is that a unique center wavelength cannot always be determined.

The second possibility is to trace the wavelength of a single longitudinal mode while increasing the current, using a high-resolution optical spectrometer. The shift of the wavelength λ_{mode} of a mode is determined by the temperature dependence of its modal phase index, which results in a much weaker coefficient $\mathrm{d}\lambda_{\text{mode}}/\mathrm{d}T$ than for the center wavelength $\mathrm{d}\lambda_{\text{center}}/\mathrm{d}T$ of the emission spectrum. This method yields more reliable results for the thermal resistance. In any case, $\mathrm{d}\lambda_{\text{center}}/\mathrm{d}T$ or $\mathrm{d}\lambda_{\text{mode}}/\mathrm{d}T$ has to be determined in advance by measuring the functions $\lambda_{\text{center}}(T)$ or $\lambda_{\text{mode}}(T)$, respectively, where T is the chip temperature.

27.2.3 Comparison of Simulated and Measured CW Characteristics

In Figure 27.5 the measured $P - I$, $U - I$ and $\eta_c - I$ characteristics (solid lines) are compared with the results obtained with the phenomenological model (dashed lines) presented above in Section 27.2.1. The conversion efficiency η_c is defined as

$$\eta_c = \frac{P_{\text{out}}}{UI} \tag{27.23}$$

The bending of the power–current characteristics at high bias is caused by the temperature-induced increase of the threshold current and decrease of the slope efficiency (determined by the parameters T_0 and T_1 here) due to the power dissipation. It leads to what is commonly referred to as “thermal roll-over.” However, the measured bending is stronger than the simulated one.

This discrepancy is caused by the fact that there are nonthermal reasons for the bending of the P–I characteristic at high bias (also referred as “power saturation”) which cannot be addressed by the phenomenological laser models based on parameters measured at low bias. For example, bending of the conduction and valence bands and carrier accumulation effects occurring at large bias leading to enhanced nonstimulated recombination and internal absorption [11] result in an increased threshold current and a decreased external differential efficiency. Other effects are longitudinal spatial holeburning (LSH), nonlinear gain compression, and two-photon absorption as discussed in Sections 27.3.2 and 27.3.5, which result in a saturation of the output power.

These effects could be modeled phenomenologically by additional explicit current dependencies $I_{\text{thr}}(I)$ and $\eta_{\text{ext}}(I)$ with parameters j'_{thr} and j_{sat},

$$I_{\text{thr}} = I_{\text{thr},0} + WLj'_{\text{thr}}\left(I - I_{\text{thr},0}\right) \tag{27.24}$$

and

$$\eta_{\text{ext}} = \frac{\eta_{\text{ext},0}}{1 + \frac{I - I_{\text{thr},0}}{WLj_{\text{sat}}}}, \tag{27.25}$$

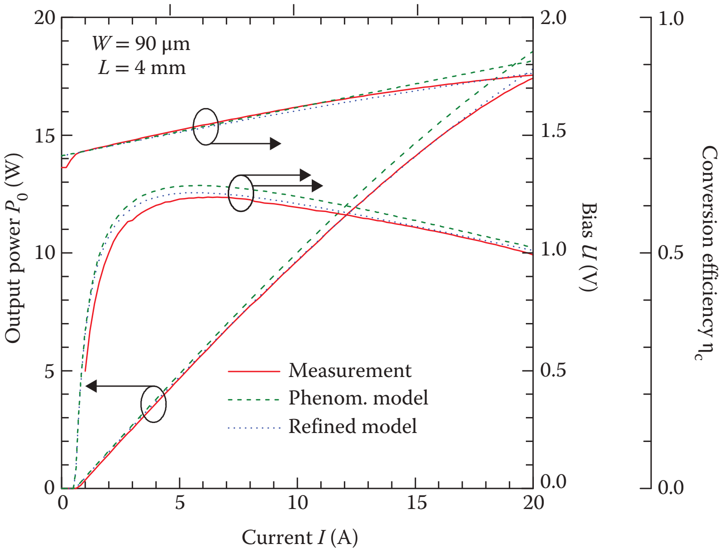

FIGURE 27.5 Output power at $z = 0$ (left axis), applied voltage (right axis), and conversion efficiency (right-most axis) versus injection current. Solid line indicates measurement and dashed line indicates phenomenological laser model. Dotted line indicates refined model.

respectively. The proportionality factor $j'_{\mathrm{thr}} > 0$ models the increase of the threshold current due to nonthermal effects with $I_{\mathrm{thr},0}$ given by Equation 27.6. Similarly, the parameter $j_{\mathrm{sat}} > 0$ causes a reduction of the external differential efficiency where $\eta_{\mathrm{ext},0}$ is given by Equation 27.7.

Furthermore, the series resistance varies also far above threshold, either caused by carrier accumulation (differential resistance $r'_{\mathrm{s}} < 0$) or temperature effects ($r'_{\mathrm{s}} > 0$),

$$r_{\mathrm{s}} = r_{\mathrm{s},0} + \frac{r'_{\mathrm{s}}}{WL}\left(I - I_{\mathrm{thr},0}\right) \tag{27.26}$$

With the refined model (dotted lines), a better match can be achieved as Figure 27.5 reveals. Note that the used parameters j'_{thr}, j_{sat}, and r'_{s} given in Table 27.1 are guess values. An even better agreement between theory and experiment could be achieved by employing a fitting procedure, probably.

27.3 Models for the Optical Power

In this section, we investigate the profile of the optical power in the cavity in more detail and derive some of the equations used in Section 27.2. Furthermore, we discuss the nonthermal effects responsible for the saturation of the output power with increasing injection current.

27.3.1 Basic Relations

The total power P can be always separated into forward and backward propagating parts,

$$P(z,t) = P^{+}(z,t) + P^{-}(z,t) \tag{27.27}$$

In an FP cavity, they fulfil the partial differential equations ($\partial_t = \partial/\partial t$, $\partial_z = \partial/\partial z$)

$$\partial_t P^{\pm} \pm v_{\mathrm{g}} \partial_z P^{\pm} = v_{\mathrm{g}}(g_{\mathrm{m}} - \alpha_{\mathrm{m}})P^{\pm} + \frac{\dot{P}_{\mathrm{sp}}}{2} \tag{27.28}$$

subject to the boundary conditions

$$\begin{aligned} P^{+}(0,t) &= R_0 P^{-}(0,t) \\ P^{-}(L,t) &= R_L P^{+}(L,t) \end{aligned} \tag{27.29}$$

Here $g_{\mathrm{m}} - \alpha_{\mathrm{m}}$ is the modal net gain in the cavity with g_{m} being the modal gain and α_{m} the modal losses, L the cavity length, $v_{\mathrm{g}} = c/n_{\mathrm{g}}$ the group velocity with n_{g} being the modal group index, and $\dot{P}_{\mathrm{sp}}$ the rate of spontaneous emission coupled into the lasing modes. The total output power at the facets is $P_{\mathrm{out}} = P_0 + P_{\mathrm{L}}$ with

$$P_0 = (1 - R_0)P^{-}(0), \quad P_{\mathrm{L}} = (1 - R_{\mathrm{L}})P^{+}(L) \tag{27.30}$$

Integrating Equation 27.28 along z, adding both equations, and taking into account Equation 27.29 we obtain the power balance

$$\frac{1}{v_{\mathrm{g}}}\frac{\mathrm{d}\bar{P}}{\mathrm{d}t} = -\frac{P_{\mathrm{out}}}{L} + \frac{1}{L}\int_0^L (g_{\mathrm{m}} - \alpha_{\mathrm{m}})P\,\mathrm{d}z + \frac{1}{v_{\mathrm{g}}L}\int_0^L \dot{P}_{\mathrm{sp}}\,\mathrm{d}z \tag{27.31}$$

with the average internal power

$$\bar{P} = \frac{1}{L}\int_0^L (P^+ + P^-)\,\mathrm{d}z. \tag{27.32}$$

In what follows, we consider the steady state ($\partial_t = 0$) and two special cases, namely the case around threshold and the case above threshold.

27.3.1.1 Steady State around Threshold

Around threshold both $g_\mathrm{m} - \alpha_\mathrm{m}$ and $\dot{P}_\mathrm{sp}$ can be assumed to be constant (z-independent). Therefore, the solution of Equation 27.28 taking into account Equation 27.29 is

$$P^\pm(z) = \frac{\dot{P}_\mathrm{sp}}{2v_\mathrm{g}} \cdot \frac{C^\pm e^{\pm(g_\mathrm{m}-\alpha_\mathrm{m})z} - 1}{g_\mathrm{m} - \alpha_\mathrm{m}} \tag{27.33}$$

with

$$C^+ = \frac{1 - R_0 + (1 - R_L)R_0 e^{(g_\mathrm{m}-\alpha_\mathrm{m})L}}{1 - R_0 R_L e^{2(g_\mathrm{m}-\alpha_\mathrm{m})L}} \tag{27.34}$$

$$C^- = \frac{1 - R_L + (1 - R_0)R_L e^{(g_\mathrm{m}-\alpha_\mathrm{m})L}}{1 - R_0 R_L e^{2(g_\mathrm{m}-\alpha_\mathrm{m})L}} e^{(g_\mathrm{m}-\alpha_\mathrm{m})L}. \tag{27.35}$$

The ratio between the outcoupled powers at the facets is given by

$$\frac{P_L}{P_0} = \frac{1 - R_L}{1 - R_0} \cdot \frac{1 + R_0 e^{(g_\mathrm{m}-\alpha_\mathrm{m})L}}{1 + R_L e^{(g_\mathrm{m}-\alpha_\mathrm{m})L}} \tag{27.36}$$

If the spontaneous emission approaches zero, $C^\pm$ must go to infinity to obtain a nonzero output power, which yields the so-called threshold condition $g_\mathrm{m} - \alpha_\mathrm{m} = \alpha_\mathrm{out}$.

27.3.1.2 Steady State above Threshold

Above threshold $g_\mathrm{m} - \alpha_\mathrm{m}$ cannot longer be assumed to be constant due to LSH, but the spontaneous emission can be neglected, $\dot{P}_\mathrm{sp} = 0$. Hence, the solution of Equation 27.33 is

$$P^\pm(z) = P^\pm(0) e^{\pm \int_0^z [g_\mathrm{m}(z') - \alpha_\mathrm{m}(z')]\,dz'}. \tag{27.37}$$

In order to obey the boundary conditions Equation 27.29, the threshold condition

$$g_\mathrm{thr} = \frac{1}{L}\int_0^L \alpha_\mathrm{m}\,\mathrm{d}z + \alpha_\mathrm{out} \tag{27.38}$$

must hold, where α_out are the outcoupling losses Equation 27.9 and

$$g_\mathrm{thr} = \frac{1}{L}\int_0^L g_\mathrm{m}\,\mathrm{d}z \tag{27.39}$$

is the threshold gain. The ratio between the outcoupled powers

$$\frac{P_\mathrm{L}}{P_0} = \frac{1-R_\mathrm{L}}{1-R_0}\sqrt{\frac{R_0}{R_\mathrm{L}}} \tag{27.40}$$

follows from the boundary conditions Equation 27.29, the general relation

$$\partial_z(P^+P^-) = 0 \tag{27.41}$$

and from the ratio between the internal and external powers given by Equation 27.30.

27.3.1.3 External Differential Efficiency

From the threshold condition Equation 27.38, the modal threshold gain g_thr can be calculated and from that, depending on the model used, the threshold carrier density N_thr, the threshold voltage U_thr, or the threshold current I_thr. Finally, the external differential efficiency is the ratio between the energy leaving the cavity and the energy generated by stimulated recombination (cf. Equation 27.47),

$$\eta_\mathrm{ext} = \frac{P_\mathrm{out}}{\hbar\omega\int R_\mathrm{st}\,\mathrm{d}V} = \frac{P_\mathrm{out}}{\int g_\mathrm{m}P\,\mathrm{d}z}. \tag{27.42}$$

Assuming z-independent $g_\mathrm{m} - \alpha_\mathrm{m}$, the relation between the total output power and the average internal power follows from Equations 27.31 and 27.38 to

$$P_\mathrm{out} = \alpha_\mathrm{out}L\bar{P} \tag{27.43}$$

and the external differential efficiency is

$$\eta_\mathrm{ext} = \frac{\alpha_\mathrm{out}}{g_\mathrm{thr}} \tag{27.44}$$

27.3.2 Rigrod Model

In order to determine the variation of the modal gain along z above threshold, a model for the carrier densities is required. The simplest model consists of a rate equation for the excess carrier density N in the active region

$$\frac{\mathrm{d}N}{\mathrm{d}t} = \frac{j}{ed} - R(N,P) \tag{27.45}$$

with a constant injection current density j. The recombination rate [12]

$$R = R_\text{non-rad} + R_\mathrm{sp} + R_\mathrm{st} \tag{27.46}$$

consists of nonradiative (Shockley–Read–Hall, Auger) recombination $R_\text{non-rad}$, radiative spontaneous recombination R_sp, and radiative stimulated recombination:

$$R_\mathrm{st} = \frac{g_\mathrm{m}P}{dW\hbar\omega} \tag{27.47}$$

where $P = P^+ + P^-$, g_m is the modal gain, $\hbar\omega$ the photon energy, d the thickness of the active region, and W the width of the active region.[†]

Even for the steady-state above threshold, there exists no analytical solution of Equations 27.28 and 27.45. However, if the nonstimulated recombination rate and the gain are linearized,

$$R_\text{non-rad} + R_\text{sp} = \frac{N}{\tau_N} \tag{27.48}$$

and

$$g_\mathrm{m} = g'_\mathrm{m}(N - N_\mathrm{tr}), \tag{27.49}$$

respectively, and inserted into Equation 27.45, the excess carrier density N can be determined.

Introducing the obtained expression for N again into Equation 27.49 yields

$$g_\mathrm{m} = \frac{g_0}{1 + \frac{P}{P_\mathrm{sat}}} \tag{27.50}$$

with the unsaturated gain

$$g_0 = \frac{g'_\mathrm{m}\tau_N}{ed}(j - j_\mathrm{tr}) \tag{27.51}$$

where g'_m is the differential gain, τ_N the effective carrier lifetime, $j_\mathrm{tr} = edN_\mathrm{tr}/\tau_N$ the transparency current density, N_tr the transparency carrier density, and

$$P_\mathrm{sat} = \frac{dW\hbar\omega}{g'_\mathrm{m}\tau_N} \tag{27.52}$$

is the saturation power. For the typical values of $d = 10$ nm, $W = 100$ µm, $g'_\mathrm{m} = 10 \cdot 10^{-18}\ \mathrm{cm}^2$, $\tau_N = 1$ ns, and $\hbar\omega = 1.24$ eV, we obtain $P_\mathrm{sat} = 0.2$ W, which is much smaller than the internal power of state-of-the-art broad-area lasers operated far above threshold.

The resulting equation for the steady-state

$$\pm\frac{\mathrm{d}P^\pm}{\mathrm{d}z} = \left(\frac{g_0}{1 + \frac{P^+ + P^-}{P_\mathrm{sat}}} - \alpha_\mathrm{m}\right)P^\pm + \frac{\dot{P}_\mathrm{sp}}{2v_\mathrm{g}} \tag{27.53}$$

has been analytically solved by Rigrod [13] neglecting spontaneous emission and modal losses ($\dot{P}_\mathrm{sp} = \alpha_\mathrm{m} = 0$). For the general case a numerical solution has to be employed.

For $P_\mathrm{sat} \ll P$, $P^+ \ll P^-$, $g_\mathrm{m} \approx g_0 P_\mathrm{sat}/P^-$ and the resulting equation

$$-\frac{\mathrm{d}P^-}{\mathrm{d}z} = g_0 P_\mathrm{sat} - \alpha_\mathrm{m}P^- + \frac{\dot{P}_\mathrm{sp}}{2v_\mathrm{g}} \tag{27.54}$$

[†] Equation 27.47 follows from Equation 27.140 by averaging over the active region $1/(\mathrm{d}W)\iint \mathrm{d}x\mathrm{d}y$, taking into account Equation 27.106 and $n_\mathrm{m} = \bar{n}$.

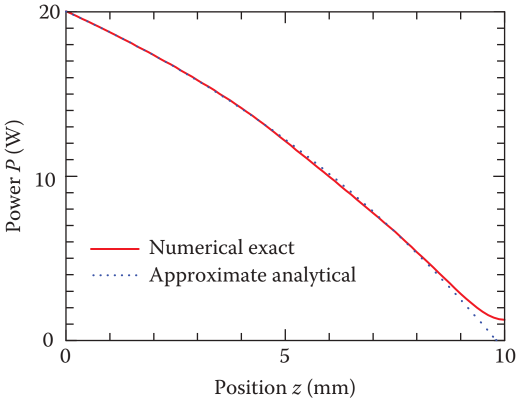

FIGURE 27.6 Longitudinal profiles of the total power for the parameters in Table 27.2 based on the numerical solution of Equation 27.53 (solid) and the analytical solution of Equation 27.55 (dashed).

has an analytical solution, too, namely

$$P(z) \approx P^{-}(z) = P^{-}(0)e^{\alpha_{\mathrm{m}} z} + \left(g_0 P_{\mathrm{sat}} + \frac{\dot{P}_{\mathrm{sp}}}{2v_{\mathrm{g}}} \right) \left(\frac{1 - e^{\alpha_{\mathrm{m}} z}}{\alpha_{\mathrm{m}}} \right) \tag{27.55}$$

In Figure 27.6, the exact and approximate solutions are compared. Except near the right facet located at $z = 10$ mm where the condition $P^{+} \ll P^{-}$ is not fulfilled, a good agreement can be noted. Note that according to Equation 27.55 $P(z)$ varies linearly for vanishing modal absorption $\alpha_{\mathrm{m}} = 0$.

27.3.3 Treat-Power-as-a-Parameter Method

The equation for the steady-state longitudinal power profile above threshold

$$\pm \frac{dP^{\pm}}{dz} = \left[g_{\mathrm{m}}(P) - \alpha_{\mathrm{m}} \right] P^{\pm} \tag{27.56}$$

subject to the boundary conditions Equation 27.29 can be conveniently solved numerically by the "treat-power-as-a-parameter" (TPP) method as introduced for the simulation of DFB lasers in Reference [14] and applied to high-power Fabry–Pérot lasers in Reference [15]. In a first step, g_{m} is calculated as a function of an external parameter (such as injection current I or bias U) and the power P, and stored in a look-up table, together with other quantities of interest (e.g., λ and I). In a second step, the boundary value problem (Equation 27.56) is solved by interpolating g_{m} in the look-up table. For given I or U, one chooses a guess value $P^{-}(0)$ and integrates Equation 27.56 from $z = 0$ to $z = L$ where typically the boundary condition is not fulfilled. Therefore, the function $P^{-}(L) - R_{\mathrm{L}} P^{+}(L)$ has to be nullified by varying $P^{-}(0)$. It is also possible to give $P^{-}(0)$ and to vary I or U to fulfil the boundary condition.

The lasing wavelength can be determined approximately by searching the maximum of integral $\int_0^L (g_{\mathrm{m}} - \alpha_{\mathrm{m}})\, dz$ with respect to λ. LSH is included automatically via the power dependence of g_{m} in Equation 27.56. If g_{m} is evaluated at the average power $\bar{P}$ in the cavity, the usual model neglecting LSH is recovered.

27.3.4 LSH and the Impact of Series Resistance and Internal Loss

The assumption of a constant injection current density in Equation 27.45 results in an overestimation of spatial hole burning. At the ohmic contacts, the quasi-Fermi potentials of electrons and holes, φ_n and

φ_p, respectively, are fixed and given by the applied bias, $\varphi_n = 0$ at the n-contact and $\varphi_p = U$ at the p-contact. The injection current density can be set equal to the hole current density and thus proportional to the gradient of the quasi-Fermi potential of the holes at the boundary between the active region and the p-doped region. Assuming isothermal conditions, one-dimensional current flow, and vanishing recombination outside the active region as well as infinitely high electron conductivity ($\sigma_n \to \infty$) in the n-doped region,

$$j(N) = \frac{U - \varphi_{\mathrm{F}}(N)}{r_{\mathrm{s}}} \tag{27.57}$$

can be derived from Equations 27.138 and 27.149 for the region beneath the p-contact, where $\varphi_{\mathrm{F}}(N) = \varphi_p(N) - \varphi_n(N)$ is the Fermi voltage and

$$r_{\mathrm{s}} = \sum_i \frac{d_i}{\sigma_{\mathrm{p},i}} \tag{27.58}$$

is the area-related total series resistance of the p-doped layers with thicknesses d_i and hole conductivities $\sigma_{\mathrm{p},i}$ between the active region and p-contact stripe.

For parabolic bands the relations between quasi-Fermi potentials φ_n and φ_p and the electron and hole densities n and p, respectively, are given by

$$e\varphi_n = -k_{\mathrm{B}}T\mathcal{F}_i^{\mathrm{inv}}\left(\frac{n}{N_{\mathrm{c}}}\right) - E_{\mathrm{c}} + e\varphi \qquad \text{and} \qquad e\varphi_p = k_{\mathrm{B}}T\mathcal{F}_i^{\mathrm{inv}}\left(\frac{p}{N_{\mathrm{v}}}\right) - E_{\mathrm{v}} + e\varphi, \tag{27.59}$$

where E_{c}, E_{v} are the (effective) conduction and valence band edges, N_c and N_v the conduction and valence band edge density of states, $\mathcal{F}_i^{\mathrm{inv}}$ the inverse Fermi integrals with $i = 1/2$ for bulk and $i = 0$ for QW active regions and φ the electrostatic potential. Hence, the Fermi voltage is given by

$$\varphi_{\mathrm{F}} = \frac{k_{\mathrm{B}}T}{e}\left[\mathcal{F}_i^{\mathrm{inv}}\left(\frac{p}{N_{\mathrm{v}}}\right) + \mathcal{F}_i^{\mathrm{inv}}\left(\frac{n}{N_{\mathrm{c}}}\right)\right] + \frac{E_{\mathrm{g}}}{e} \tag{27.60}$$

where $E_{\mathrm{g}} = E_{\mathrm{c}} - E_{\mathrm{v}}$ is the energy gap. In Equation 27.57, local charge neutrality $p - n + p_{\mathrm{D}} - n_{\mathrm{A}} = 0$ is assumed so that the electron and hole densities are given by $n = n_0 + N$ and $p = p_0 + N$, respectively, with n_0, p_0 being the equilibrium densities and N the excess carrier density.

For $r_{\mathrm{s}} \to \infty$, the usual model of a constant current density is recovered, whereas for $r_{\mathrm{s}} \to 0$, the carrier density becomes constant. This can be more readily seen by expanding $\varphi_{\mathrm{F}}(N)$ around the average carrier density $\bar{N}$ which yields

$$j(N) = \bar{j} - \frac{\varphi_{\mathrm{F}}'}{r_{\mathrm{s}}}(N - \bar{N}) \tag{27.61}$$

where the transition between both models (constant current density and constant carrier density, respectively) is governed by the parameter $\varphi_{\mathrm{F}}'/r_{\mathrm{s}}$.

Equations 27.56 and 27.45 with Equations 27.46, 27.47, and 27.57 assuming linear recombination and gain models, Equations 27.48 and 27.49, respectively, have been solved using the TPP method. The parameters used are given in Table 27.2. In Figure 27.7a, the influence of the series resistance on the power–current characteristics is clearly visible. For $r_{\mathrm{s}} = 10^{-6}\ \Omega \cdot \mathrm{cm}^2$ almost the same characteristics as without LSH is obtained.

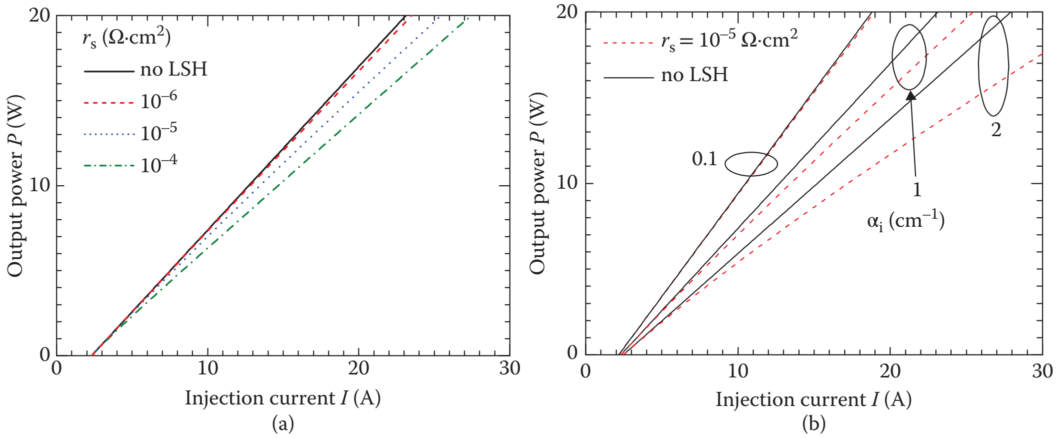

FIGURE 27.7 Power–current characteristics without (black solid) and with longitudinal spatial holeburning for different series resistances r_s and modal losses α_m. (a) Influence of the series resistance for a modal loss of $\alpha_m = 1\ \text{cm}^{-1}$ and (b) Influence of modal losses for a series resistance of $r_s = 10^{-5}\Omega \cdot \text{cm}^2$.

TABLE 27.2 Laser Parameters Used to Investigate Power Saturation Effects

Parameter	Symbol	Value	Unit
Front facet reflectivity	R_0	0.001	
Rear facet reflectivity	R_L	0.95	
Width of active region	W	100	μm
Thickness of active region	d	10	nm
Cavity length	L	1	cm
Modal losses	α_m	1	cm^{-1}
Rate of spontaneous emission	$\dot{P}_{sp}$	0	
Differential modal gain	g'_m	$10 \cdot 10^{-18}$	cm^2
Transparency carrier density	N_{tr}	10^{18}	cm^{-3}
Carrier lifetime	τ_N	1	ns
Wavelength	λ	1000	nm
Series resistance	r_s	10^{-5}	Ω · cm^2
Temperature	T	300	K
Conduction band density of states	N_c	$0.4 \cdot 10^{18}$	cm^{-3}
Valence band density of states	N_v	$13 \cdot 10^{18}$	cm^{-3}

If there are no internal losses, LSH has no impact on the slope efficiency at all, because from Equation 27.31

$$P_{\text{out}} = \int_0^L g_m P\,dz \tag{27.62}$$

follows and Equation 27.42 gives $\eta_{\text{ext}} = 1$ independent of the spatial profiles of g_m and P. As Figure 27.7b reveals, the difference between the power–current characteristics calculated with and without spatial hole burning increases with increasing modal losses.

The longitudinal profiles of forward, backward, and total power; modal gain; and injected current density are shown in Figure 27.8 for the extreme values of r_s. For a high value of r_s (Figure 27.8a), the injected current density is almost constant, so that the gain varies strongly. In contrast, for a low value of r_s (Figure 27.8b) the injected current density varies strongly so that the gain is almost constant. This results in quite different power profiles. In particular, the averaged internal power differs by almost a factor of 2 ($\bar{P} = 11$ W versus $\bar{P} = 6$ W). Besides by a reduction of the internal losses, the series resistance or the asymmetry in the facet coating ("unfolding the cavity" [16]) LSH could be mitigated by a tapered lateral waveguide design where the contact width W increases from the rear facet toward the front facet [17,18].

27.3.5 Discussion of Further Nonthermal Power Saturation Effects

27.3.5.1 Nonlinear Gain Compression

There are a couple of effects that can be described by an effective decrease of the optical gain with increasing photon density $|u|^2$ or power P, described by the functions

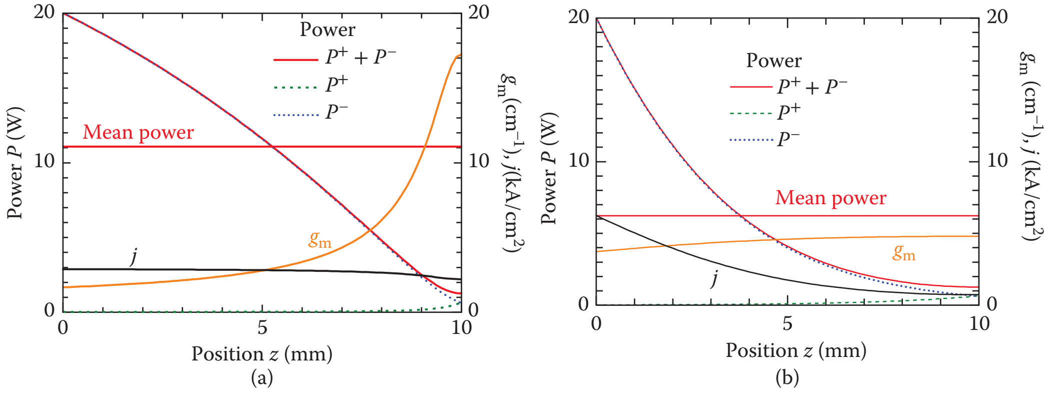
$$g = \frac{g_0}{1 + \epsilon_s |u|^2} \quad \text{or} \quad g = \frac{g_0}{1 + \frac{P}{P_s}} \tag{27.63}$$

similar to Equation 27.50. The relation between the gain compression factor ϵ_s and the saturation power P_s is given by

$$P_s = \frac{dWv_g \hbar\omega}{\Gamma \epsilon_s} \tag{27.64}$$

where Γ is the optical confinement factor of the active region. The gain compression factor is of the order $\epsilon_s \propto 10^{-17}$ cm^3, which results in a saturation power of $P_s \propto 150$ W for typical values $d = 10$ nm, $W = 100$ µm, $\Gamma = 0.01$, $n_g = 4$, $\lambda_0 = 1$ µm. Hence gain compression effects are of minor importance for CW lasers, but might result in power saturation of pulsed lasers where $P = 100$ W from a stripe width of $W = 100$ µm can be achieved [19].

The first effect contributing to nonlinear gain compression is spectral hole burning, which arises due to the interplay of the depletion of the carriers at the lasing wavelength due to stimulated emission and



(a)

(b)

FIGURE 27.8 Longitudinal profiles of forward (P^+), backward (P^-), and total ($P = P^+ + P^-$), power, modal gain g_m, and injected current density j for two series resistances r_s at an output power of $P_{out} = 20$ W. (a) Series resistance $r_s = 10^{-4}$ cm^2 and (b) series resistance $r_s = 10^{-6}$ cm^2. The horizontal line is the averaged internal (mean) power $\bar{P}$.

the relaxation of injected carriers into the depleted spectral region. At high power densities, the relaxation processes due to intraband carrier–carrier scattering with a time scale of 50–100 fs are not sufficiently fast to fill the spectral hole formed by the optical transitions. This results in a reduction of the optical gain around the lasing wavelength.

A second effect is the increase of the temperatures of the carrier distributions beyond the lattice temperature by the removal of "cold" carriers near the band-edges due to stimulated emission or by the transfer of carriers to high energies within the bands by free-carrier, inter-valence band and two-photon absorption. The temperature increase results in a reduction of the optical gain, too.

Nonlinear gain compression also can be caused by lateral spatial hole burning [20] and the Bragg grating induced by the standing waves in Fabry–Pérot lasers [21]. The impact of both the gain compression and two-photon absorption on the power–current characteristics is discussed in the next section (cf. Figure 27.9).

27.3.5.2 Two-Photon Absorption

The two-photon absorption coefficient β is described in more detail in Section 27.5.2. The resulting modal absorption for a broad-area laser with a lateral top-hat intensity profile is given by (cf. Equation 27.121)

$$\alpha_{2,\mathrm{m}} = \frac{\int n_{\mathrm{r}}(x,y)\beta(x,y)|\Phi(x,y)|^4\,\mathrm{d}x\mathrm{d}y}{n_{\mathrm{m}}(\int |\Phi(x,y)|^2\,\mathrm{d}x\mathrm{d}y)^2}P \approx \frac{\int n_{\mathrm{r}}(y)\beta(y)|\phi(y)|^4\,\mathrm{d}y}{n_{\mathrm{m}}(\int |\phi(y)|^2\,\mathrm{d}y)^2}\frac{P}{W} = \frac{\bar{\beta}_{\mathrm{m}}}{A_{\mathrm{m}}}P, \tag{27.65}$$

where ϕ is the profile of the vertical mode, W the lateral width, n_{m} the modal index, and A_{m} the mode area given by

$$A_{\mathrm{m}} = \frac{W(\int |\phi(y)|^2\,\mathrm{d}y)^2}{\int |\phi(y)|^4\,\mathrm{d}y} \tag{27.66}$$

and

$$\bar{\beta}_{\mathrm{m}} = \frac{\int n_{\mathrm{r}}(y)\beta(y)|\phi(y)|^4\,\mathrm{d}y}{n_{\mathrm{m}}\int |\phi(y)|^4\,\mathrm{d}y} \tag{27.67}$$

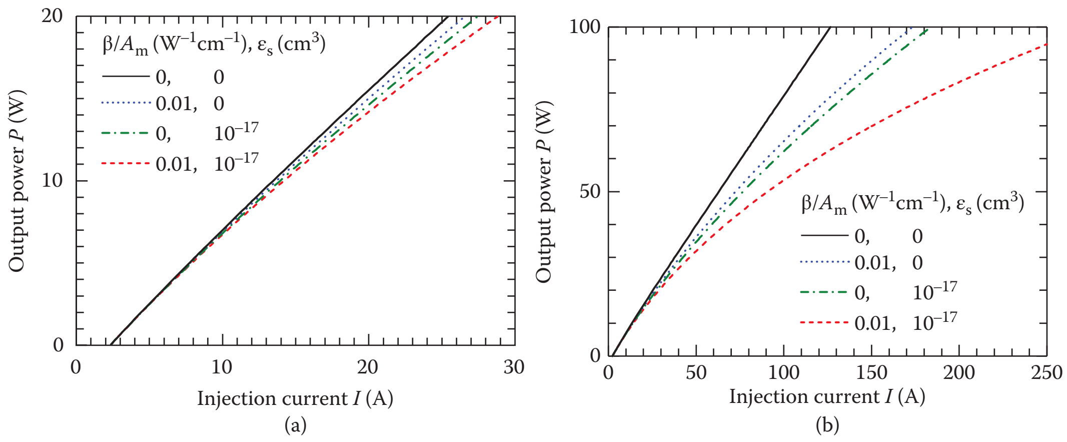


FIGURE 27.9 Impact of nonlinear-gain compression ϵ_{s} and two-photon absorption $\bar{\beta}_{\mathrm{m}}/A_{\mathrm{m}}$ on the power–current characteristics. (a) Power range corresponding to CW operation. (b) Power range corresponding to pulsed operation.

Approximating the intensity profile of the vertical mode by a Gaussian with a full width d_{1/e^2} at $1/e^2$ maximum,

$$\phi^2(y) = e^{-8y^2/d^2_{1/e^2}} \tag{27.68}$$

the mode area is $A_\mathrm{m} = \frac{\sqrt{\pi}}{2} d_{1/e^2} W \approx d_{1/e^2} W$. Assuming an averaged two-photon absorption coefficient of $\bar{\beta}_\mathrm{m} = 15\ \mathrm{cm \cdot GW^{-1}}$ (cf. Figure 27.12a) and $d_{1/e^2} = 1.5\ \mu\mathrm{m}$ as appropriate for a high-power laser we obtain $\bar{\beta}_\mathrm{m}/d_{1/e^2} = 10^{-4}\ \mathrm{W^{-1}}$. For $W = 100\ \mu\mathrm{m}$ and $P = 10$ W this results in a modal absorption coefficient of $\alpha_{2,\mathrm{m}} = 0.1\ \mathrm{cm^{-1}}$. Note that the modal two-photon absorption is maximal at minimum d_{1/e^2}, i.e., for a strong optical confinement. The secondary two-photon loss mechanism due to intraband absorption caused by the free carriers generated by two-photon absorption is strongly dependent on the carrier lifetime and the effective drift-diffusion length. In most cases, the resulting absorption coefficient can be neglected, except in structures where the intensity peak of the vertical mode is not located at the position of the active layer [22].

Figure 27.9 shows the impact of nonlinear gain compression and two-photon absorption on the power–current characteristics using the model presented in Section 27.3.4 with the parameters given in Table 27.2. The following conclusions can be drawn: First, a gain compression factor $\epsilon_\mathrm{s} = 10^{-17}\ \mathrm{cm^3}$ (saturation power $P_\mathrm{s} = 150$ W) or a two-photon absorption coefficient $\bar{\beta}/A_\mathrm{m} = 0.01\ (\mathrm{Wcm})^{-1}$ act very similar. Second, at a current of $I = 15$ A, which is typical for lasers operating in CW mode, the combination of both effects results in a reduction of the optical power by 10% (2 W; cf. Figure 27.9a). However, at a current of $I = 125$ A, which can be reached under pulsed operation [19], the power is reduced from 100 to 60 W, which seems a little bit too large, considering that leakage currents are not accounted for at all. Hence, either the gain compression factor or the two-photon absorption coefficient or both are smaller in reality than assumed here.

27.3.5.3 Leakage Currents

Leakage currents caused by the transport of carriers into regions without stimulated recombination can be divided into vertical and lateral ones. Vertical leakage currents are minority currents caused by the accumulation and subsequent recombination of electrons and holes in the p-doped and n-doped, respectively, optical confinement layers. This effect results in an increased free-carrier absorption, too. An analytical investigation of the carrier accumulation in the confinement layers and its impact on the power–current characteristics can be found in Reference [23] and an exact treatment based on the numerical solution of the drift-diffusion equations has been given in Reference [11,24].

The electron current flowing into the p-doped region can be obtained by integrating the continuity equation for the electron current density (Equation 27.137) over the p-doped region between the upper boundary of the active region $y = y_p$ and the p-metallization for the steady state,

$$\int_{\partial(\text{p-region})} \boldsymbol{j}_n \cdot \boldsymbol{n} dS = e \int_{\text{p-region}} R\, dV \tag{27.69}$$

where ∂(p-region) denotes the surface of the p-doped region with $\boldsymbol{n}$ being the normal vector. Assuming that the normal components of the electron current density vanish at the outer boundaries including the p-contact, we obtain the electron leakage current

$$I_\mathrm{n,leak} = \iint j_{n,y}|_{y=y_p}\, \mathrm{d}x\mathrm{d}z. \tag{27.70}$$

Hence, the electron leakage current can be calculated either from the electron current density at the boundary between active region and p-doped region or by integrating the recombination rate over the corresponding volume.

Figure 27.10a and b shows the vertical profiles of the current densities and the recombination rate of the asymmetric super-large optical-cavity structure published in [10] at a current of $I = 15$ A. Figure 27.10a reveals that for a properly designed structure the hole current flowing into the n-doped region can be neglected. The leakage current calculated from the electron current density at $y = 1.9$ μm is $I_{\mathrm{n,leak}} = 0.44$ A, which is also obtained from the integration of the recombination rate. The relative fraction of the leakage current is $(I - I_{\mathrm{n,leak}})/I = 0.97$, which coincides with the internal efficiency $\eta_{\mathrm{i}} = 0.97$, obtained from the length-dependent measurement of the external differential efficiency as described in 27.2.

With increasing bias the leakage current increases due to the bending of the band edges as shown in Reference [11], which contributes to the roll-over of the power–current characteristics. The electron leakage current can be reduced by an increase of the energy gap and doping level or a decrease of the thickness of the p-doped optical confinement layer as it is the case in extreme-asymmetric super large optical cavities. However, one should keep in mind that an increase of the energy gap results in a decrease of the electrical conductivity in the AlGaAs material system, an increase of the doping results in an increase of the free-carrier absorption and an increase of the waveguide asymmetry results in a decrease of the field intensity at the position of the active region.

The lateral leakage current $I_{\mathrm{p,spead}}$ caused by current spreading in the p-doped region can be reduced by an insulation of the highly doped p-contact and p-cladding layers beyond the p-metallization by implantation, diffusion of impurities, or etching as indicated in Figure 27.1 or by implementing a reverse-biased p-n junction. The lateral leakage current due to the diffusion of the carriers along the active region is more difficult to mitigate.

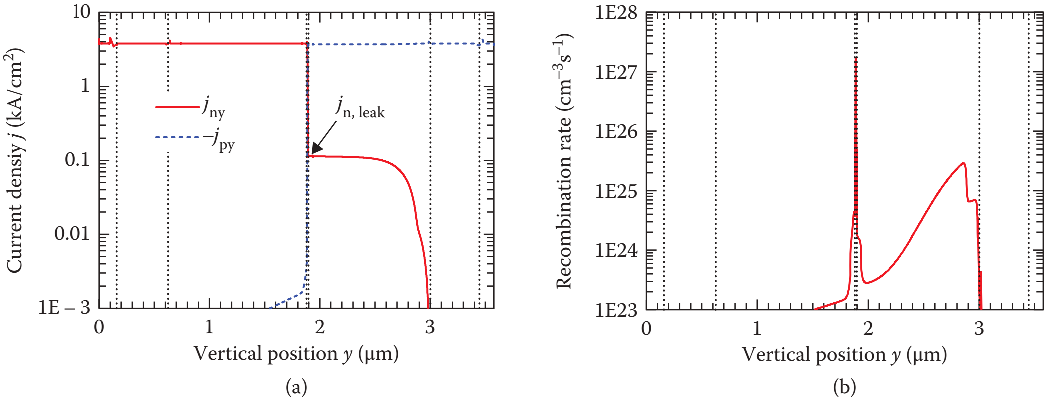
An approximate expression for $I_{\mathrm{p,spead}}$ has been derived in Reference [25],

$$\frac{I_{\mathrm{p,spead}}}{L} \approx -2\frac{\partial \varphi_{\mathrm{F}}}{\partial x}\Big|_{x=W/2} \sum_i \sigma_{\mathrm{p},i} d_i \tag{27.71}$$

where φ_{F} is the Fermi voltage given in Equation 27.60, $\sigma_{\mathrm{p},i}$ the hole conductivity of layer i and d_i the corresponding thickness. The derivative has to be taken at the edge of the p-contact stripe, and the summation includes all p-doped continuous semiconductor layers above the active region.

27.3.5.4 Carrier Capture

As it is well known [26–30], the carriers belonging to bound states in the QW(s) of the active region are not necessarily in thermal equilibrium with the carriers resulting from the continuum states located



(a) (b)

FIGURE 27.10 Vertical profiles of (a) current densities and (b) recombination rate for p-contact width $W = 100$ μm, cavity length $L = 4000$ μm, and output power $P = 15$ W. Heteroboundaries are indicated by dotted vertical lines. Note the logarithmic scales of the ordinates.

energetically above the QWs. It can be assumed that both types of carriers coexisting in the QW region are in quasi-equilibrium among themselves described by Fermi–Dirac statistics with independent quasi-Fermi potentials and transferred into each other by capture-escape processes. The transport of both types of carriers in the in-plane directions (x, z) can be described by classical drift diffusion. Most conveniently the bound carriers are described by sheet densities (unit $1/\mathrm{m}^2$) and appear in the rhs of the Poisson equation (27.141) as interface states.

An expression for the capture–escape rate that fulfils universal conditions such as the balance between capture and escape in case of equal quasi-Fermi potentials and no capture but finite escape in case of a fully occupied bound states has been given in [30]. For electrons (similarly for holes) it reads

$$Q_n = \frac{dn_\mathrm{f}}{\tau_\mathrm{c}}\left[1 - \frac{n_\mathrm{b}}{N_\mathrm{b}}\right]\left[1 - e^{\frac{e(\varphi_\mathrm{f}-\varphi_\mathrm{b})}{kT}}\right] \tag{27.72}$$

where n_f and n_b are the free and bound, electron densities, respectively; φ_f and φ_b are the corresponding quasi-Fermi potentials; d is the thickness of the QW(s); τ_c is the capture time; and N_b is the maximum bound electron density ($\varphi_\mathrm{b} \rightarrow -\infty$). Whereas the quasi-Fermi potentials of the free carriers depend directly on the bias applied to the contacts, the quasi-chemical potentials of the bound carriers are determined by the capture-escape rates.

The impact of the nonequilibrium between confined and unconfined carriers in high-power lasers on the power–current characteristics as a function of the hole capture time has been investigated in Reference [28], using, however, a capture-escape rate that differs from the one given in Equation 27.72.

27.4 Model for the Optical Field

We derive the parabolic paraxial wave equation based on the slowly varying amplitude and rotating wave approximations, taking into account gain dispersion, spontaneous emission, and a third-order nonlinear susceptibility. A balance equation for the electromagnetic energy density will be given.

27.4.1 Basic Three-Dimensional Equations

We start with the homogeneous Maxwell equation for the electric field $\boldsymbol{E}$ and the magnetic field $\boldsymbol{H}$:

$$\nabla \cdot \boldsymbol{D} = 0 \tag{27.73}$$

$$\nabla \cdot \boldsymbol{H} = 0 \tag{27.74}$$

$$\nabla \times \boldsymbol{E} + \mu_0 \partial_t \boldsymbol{H} = 0 \tag{27.75}$$

$$\nabla \times \boldsymbol{H} - \partial_t \boldsymbol{D} = 0 \tag{27.76}$$

where $\boldsymbol{D} = \varepsilon_0 \boldsymbol{E} + \boldsymbol{P}$ denotes the electric displacement and $\boldsymbol{P}$ the macroscopic polarization density of the material. The fields $\boldsymbol{E}$, $\boldsymbol{H}$, $\boldsymbol{D}$ depend on three spatial variables $\boldsymbol{r} = (x, y, z)$ and the time t. By applying $\nabla\times$ to Equation 27.75, ∂_t to Equation 27.76, and using Equation 27.73 we get the wave equation

$$\frac{1}{\varepsilon_0}\nabla(\nabla \cdot \boldsymbol{P}) + \nabla^2 \boldsymbol{E} = \frac{1}{c^2}\partial_{tt}\boldsymbol{E} + \mu_0 \partial_{tt}\boldsymbol{P} \tag{27.77}$$

The polarization density $\boldsymbol{P}$ contains a linear convolution of the electric field history $\boldsymbol{E}(t - \tau)$, $\tau \geq 0$, with a susceptibility function $\chi(r, \tau)$ and a second-order part which models dispersion ($\boldsymbol{P}_\mathrm{disp}$), nonlinear effects

($\boldsymbol{P}_{\mathrm{NL}}$), and spontaneous emission ($\boldsymbol{P}_{\mathrm{sp}}$):

$$\boldsymbol{P}(\boldsymbol{r},t)=\varepsilon_0\int_0^{\infty}\chi(r,\tau)\boldsymbol{E}(\boldsymbol{r},t-\tau)\,\mathrm{d}\tau+\boldsymbol{P}_{\mathrm{disp}}(\boldsymbol{r},t)+\boldsymbol{P}_{\mathrm{NL}}(\boldsymbol{r},t)+\boldsymbol{P}_{\mathrm{sp}}(\boldsymbol{r},t) \tag{27.78}$$

The spontaneous emission is modeled by introducing a spontaneous current density,

$$\partial_t\boldsymbol{P}_{\mathrm{sp}}(\boldsymbol{r},t)=\boldsymbol{J}_{\mathrm{sp}}(\boldsymbol{r},t) \tag{27.79}$$

We assume that $\boldsymbol{P}$ either is slowly varying in space, so that $\nabla\cdot\boldsymbol{P}\approx 0$ holds, or has discontinuities at boundaries between different materials. At these boundaries $\boldsymbol{E}$ and $\boldsymbol{H}$ have to fulfill certain continuity rules that can be derived from Maxwell equations. Due to the nearly planar geometry of edge-emitting lasers defined by the epitaxial layer structure, the electromagnetic field is either mainly transverse electric (TE) or transverse magnetic (TM) polarized. By assuming TE polarization and choosing a reference frequency ω_0, we have

$$\begin{aligned}\boldsymbol{E}(\boldsymbol{r},t)&=\boldsymbol{e}_x\frac{1}{2}E(\boldsymbol{r},t)\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \boldsymbol{P}_{\mathrm{disp}}(\boldsymbol{r},t)&=\boldsymbol{e}_x\frac{1}{2}P_{\mathrm{disp}}(\boldsymbol{r},t)\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \boldsymbol{P}_{\mathrm{NL}}(\boldsymbol{r},t)&=\boldsymbol{e}_x\frac{1}{2}P_{\mathrm{NL}}(\boldsymbol{r},t)\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \boldsymbol{J}_{\mathrm{sp}}(\boldsymbol{r},t)&=\boldsymbol{e}_x\frac{1}{2}j_{\mathrm{sp}}(\boldsymbol{r},t)\mathrm{e}^{i\omega_0 t}+\text{c.c.}\end{aligned} \tag{27.80}$$

where $\boldsymbol{e}_x$ denotes the unit vector in x direction, c.c. stands for complex conjugation, and $E, P_{\mathrm{disp}}, P_{\mathrm{NL}}, j_{\mathrm{sp}}$ are scalar complex-valued functions. In the slowly varying amplitude approximation the corresponding derivatives are given by

$$\begin{aligned}\partial_{tt}\boldsymbol{E}&\approx-\boldsymbol{e}_x\frac{1}{2}\left(\omega_0^2E-2i\omega_0\partial_tE\right)\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \partial_{tt}\boldsymbol{P}_{\mathrm{disp}}&\approx-\boldsymbol{e}_x\frac{1}{2}\omega_0^2P_{\mathrm{disp}}\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \partial_{tt}\boldsymbol{P}_{\mathrm{NL}}&\approx-\boldsymbol{e}_x\frac{1}{2}\omega_0^2P_{\mathrm{NL}}\mathrm{e}^{i\omega_0 t}+\text{c.c.}\\ \partial_{tt}\boldsymbol{P}_{\mathrm{sp}}&\approx\boldsymbol{e}_x\frac{1}{2}i\omega_0j_{\mathrm{sp}}\mathrm{e}^{i\omega_0 t}+\text{c.c.}\end{aligned} \tag{27.81}$$

Let $\chi(\boldsymbol{r},\omega)$ denote the Fourier transform of $\chi(\boldsymbol{r},t)$ evaluated at frequency ω. First we insert Equation 27.80 into Equation 27.78 and replace $E(\boldsymbol{r},t-\tau)$ by its first-order approximation $E(\boldsymbol{r},t)-\partial_tE(\boldsymbol{r},t)\tau$. Then we insert the result and Equation 27.80 into Equation 27.77 taking into account Equation 27.81. Finally, we multiply by $e^{-i\omega_0 t}$ and neglect the rapidly varying terms containing $e^{-i2\omega_0 t}$ (rotating wave approximation) and get

$$\begin{aligned}\Delta E=&-\frac{\omega_0^2}{c^2}E+\frac{2i\omega_0}{c^2}\partial_tE-\frac{\omega_0^2}{c^2}\chi(\boldsymbol{r},\omega_0)E+\frac{i\omega_0}{c^2}\left(2\chi(\boldsymbol{r},\omega_0)+\omega_0\partial_\omega\chi(\boldsymbol{r},\omega)_{|\omega=\omega_0}\right)\partial_tE\\ &-\mu_0\omega_0^2\left(P_{\mathrm{disp}}+P_{\mathrm{NL}}\right)+i\mu_0\omega_0j_{\mathrm{sp}}\end{aligned} \tag{27.82}$$

Consistent with the neglection of $\partial_{tt}E(\boldsymbol{r},t)$ we approximate in front of $\partial_t E(\boldsymbol{r},t)$:

$$2\chi(\boldsymbol{r},\omega_0) + \omega_0\partial_\omega\chi(\boldsymbol{r},\omega)_{|\omega=\omega_0} \approx 2\bar{\chi}(\omega_0) + \omega_0\partial_\omega\bar{\chi}(\omega)_{|\omega=\omega_0} \tag{27.83}$$

where $\bar{\chi}$ is an averaged real-valued susceptibility of the medium. This means that the spatial variation and the imaginary part of χ is considered to be a first-order correction, which can be neglected in front of the time derivative.

Introducing the complex refractive index $n^2(\boldsymbol{r},\omega) = 1 + \chi(\boldsymbol{r},\omega)$, the real-valued reference index $\bar{n}^2 = 1 + \bar{\chi}$, the real-valued group index $n_{\rm g} = \bar{n} + \omega_0\partial_\omega\bar{n}(\omega)_{|\omega=\omega_0}$ and $k_0 = \omega_0/c$, we get

$$\Delta E = 2ik_0\frac{\bar{n}n_{\rm g}}{c}\partial_t E - k_0^2 n^2 E - \mu_0\omega_0^2\left(P_{\rm disp} + P_{\rm NL}\right) + i\mu_0\omega_0 j_{\rm sp} \tag{27.84}$$

Next we remove the rapid oscillations along the longitudinal z direction with the Ansatz

$$E(\boldsymbol{r},t) = E^+(\boldsymbol{r},t){\rm e}^{-i\bar{n}k_0 z} + E^-(\boldsymbol{r},t){\rm e}^{i\bar{n}k_0 z} \tag{27.85}$$

Inserting Equation 27.85 into Equation 27.84, neglecting $\partial_{zz}E^\pm$, multiplying the result with ${\rm e}^{\pm i\bar{n}k_0 z}$, dropping rapidly varying terms containing ${\rm e}^{\pm 2i\bar{n}k_0 z}$, and dividing by $2i\bar{n}k_0$, we get

$$\begin{aligned}\frac{1}{v_{\rm g}}\partial_t E^\pm(\boldsymbol{r},t) \pm \partial_z E^\pm(\boldsymbol{r},t) &= \frac{1}{2i\bar{n}k_0}\left[(\partial_x)^2 + (\partial_y)^2\right]E^\pm(\boldsymbol{r},t) - ik_0\frac{n^2(\boldsymbol{r},\omega_0) - \bar{n}^2}{2\bar{n}}E^\pm(\boldsymbol{r},t)\\ &+ \frac{\mu_0\omega_0^2}{2i\bar{n}k_0}\left[P_{\rm disp}(\boldsymbol{r},t) + P_{\rm NL}(\boldsymbol{r},t)\right]{\rm e}^{\pm i\bar{n}k_0 z} - \frac{\mu_0\omega_0}{2\bar{n}k_0}j_{\rm sp}(\boldsymbol{r},t){\rm e}^{\pm i\bar{n}k_0 z}\end{aligned} \tag{27.86}$$

where $v_{\rm g} = c/n_g$.

Equation 27.86 must be supplemented by appropriate boundary conditions. At the plane facets of the laser located at $z = 0$ and $z = L$

$$\begin{aligned}E^+(x,y,0,t) - r_0 E^-(x,y,0,t) &= 0\\ E^-(x,y,L,t) - r_L e^{-i2\bar{n}k_0 L}E^+(x,y,L,t) &= 0\end{aligned} \tag{27.87}$$

hold. We should mention that in the paraxial approximation, the amplitude reflection coefficients r_0 and r_L are input parameters, which have to be calculated in advance.

At the transverse boundary denoted by Γ one can assume, for example, decaying fields or a perfect electric wall,

$$\lim_{|r_{\rm t}|\to\infty} E^\pm = 0 \quad \text{or} \quad E^\pm|_{r_{\rm t}\in\Gamma} = 0, \tag{27.88}$$

respectively. If only a part of the cross section of the cavity is simulated, a nonreflecting or transparent boundary condition has to be used, which models the fact that only outgoing waves should be present. A very popular method to implement a boundary condition of this type is the introduction of a so-called perfectly matched layer (PML) [31]. However, in the frequency domain, it results in a large number of spurious modes [32]. Within the slowly varying approximation discontinuities of n can only be treated by employing corresponding transition conditions, except for resonant Bragg waveguide gratings, which can be described by extra terms coupling the forward and backward propagating waves.

27.4.2 Ansatz for Dispersion, Nonlinear Susceptibility, and Spontaneous Emission

27.4.2.1 Dispersion

We use the following Ansatz for $P_{\mathrm{disp}}(\boldsymbol{r}, t)$:

$$P_{\mathrm{disp}}(\boldsymbol{r}, t) = -i\frac{n_{\mathrm{r}}(\boldsymbol{r}, t)g_{\mathrm{r}}(\boldsymbol{r}, t)k_0}{\omega_0^2\mu_0}\left[\mathcal{P}(\boldsymbol{r}, t) - E(\boldsymbol{r}, t)\right] \tag{27.89}$$

where the electric field E is subtracted to ensure that the contribution to the dispersion vanishes at the gain peak. We model dispersion via the following response function in the frequency domain [33–35]

$$\mathcal{P}(\boldsymbol{r}, \omega) = \mathfrak{L}(\boldsymbol{r}, \omega)E(\boldsymbol{r}, \omega) \tag{27.90}$$

with

$$\mathfrak{L}(\boldsymbol{r}, \omega) = \frac{\gamma(\boldsymbol{r})}{i[\omega - \omega_0 - (\omega_{\mathrm{p}}(\boldsymbol{r}) - \omega_0)] + \gamma(\boldsymbol{r})} \tag{27.91}$$

The Lorentzian $\mathfrak{L}(\boldsymbol{r}, \omega)$ achieves its maximum value 1 at the frequency ω_{p}. The imaginary part $\mathrm{Im}\,\mathfrak{L}(r, \omega)$ has a half width γ at half of the maximum. The approximation is valid only within a small frequency region around ω_0 corresponding to the frequency range of optical transitions in the active material. By multiplying Equation 27.90 with the denominator and taking the inverse Fourier transform with respect to $\omega - \omega_0$ we get the ordinary differential equation

$$\partial_t\mathcal{P}(\boldsymbol{r}, t) = \left[i(\omega_{\mathrm{p}}(\boldsymbol{r}) - \omega_0) - \gamma(\boldsymbol{r})\right]\mathcal{P}(\boldsymbol{r}, t) + \gamma(\boldsymbol{r})E(\boldsymbol{r}, t) \tag{27.92}$$

We use similar decompositions for the polarization $\mathcal{P}(\boldsymbol{r}, t)$ as for the electric field $E(\boldsymbol{r}, t)$,

$$\mathcal{P}(\boldsymbol{r}, t) = \mathcal{P}^{+}(\boldsymbol{r}, t)\mathrm{e}^{-i\tilde{n}k_0 z} + \mathcal{P}^{-}(\boldsymbol{r}, t)\mathrm{e}^{i\tilde{n}k_0 z} \tag{27.93}$$

Inserting Equations 27.93 and 27.85 into Equation 27.92, multiplying with $\mathrm{e}^{\pm i\tilde{n}k_0 z}$, and again neglecting $\mathrm{e}^{\pm 2i\tilde{n}k_0 z}$ we get

$$\partial_t\mathcal{P}^{\pm}(\boldsymbol{r}, t) = i(\omega_{\mathrm{p}}(\boldsymbol{r}) - \omega_0)\mathcal{P}^{\pm}(\boldsymbol{r}, t) + \gamma(\boldsymbol{r})\left[E^{\pm}(\boldsymbol{r}, t) - \mathcal{P}^{\pm}(\boldsymbol{r}, t)\right] \tag{27.94}$$

Dispersion can also be taken into account with higher order time derivatives [36], on a microscopic level [37–39], by means of a digital filter [40], or by a convolution integral [41].

27.4.2.2 Nonlinear Susceptibility

Considering a third-order nonlinearity and assuming an isotropic medium the nonlinear polarization density reads [42–44]

$$P_{\mathrm{NL}}(\boldsymbol{r}, t) = \varepsilon_0\frac{3}{4}\chi^{(3)}_{xxxx}(\boldsymbol{r}, t)|E(\boldsymbol{r}, t)|^2E(\boldsymbol{r}, t) \tag{27.95}$$

with the third-order susceptibility $\chi^{(3)}_{xxxx}(\omega_0; -\omega_0, -\omega_0, \omega_0)$. The optical Kerr coefficient $\tilde{n}_2$ and the two-photon absorption coefficient $\tilde{\beta}$ are defined as

$$\tilde{n}_2 - i\frac{\tilde{\beta}}{2k_0} = \frac{3}{8n_\mathrm{r}}\chi^{(3)}_{xxxx} \equiv \Delta\tilde{n}. \tag{27.96}$$

The connection with the commonly used coefficients n_2 and β related to the time-averaged intensity $I = \varepsilon_0\bar{n}c|E|^2/2$ and discussed in Section 27.5.2 is given by

$$n_2 - i\frac{\beta}{2k_0} = \frac{2\Delta\tilde{n}_2}{\varepsilon_0\bar{n}c} \equiv \Delta n_2 \tag{27.97}$$

where n_2 has the unit m^2/W and β the unit m/W.

27.4.2.3 Spontaneous Emission

The stochastic forces

$$F^{\pm}_{\mathrm{sp}}(\boldsymbol{r}, t) = -\frac{\mu_0\omega_0}{2\bar{n}k_0}j_{\mathrm{sp}}(\boldsymbol{r}, t)\mathrm{e}^{\pm i\bar{n}k_0 z} \tag{27.98}$$

in Equation 27.86 have the properties

$$\langle F^{+}_{\mathrm{sp}}(\boldsymbol{r}, t)\rangle = \langle F^{-}_{\mathrm{sp}}(\boldsymbol{r}, t)\rangle = 0 \tag{27.99}$$

$$\langle F^{+}_{\mathrm{sp}}(\boldsymbol{r}, t)F^{+*}_{\mathrm{sp}}(\boldsymbol{r}, t')\rangle = \langle F^{-}_{\mathrm{sp}}(\boldsymbol{r}, t)F^{-*}_{\mathrm{sp}}(\boldsymbol{r}', t')\rangle = \frac{2\hbar\omega_0 n_\mathrm{r}(\boldsymbol{r}, t)g(\boldsymbol{r}, t)n_{\mathrm{sp}}(\boldsymbol{r}, t)}{\bar{n}^2\varepsilon_0 c}\delta(\boldsymbol{r} - \boldsymbol{r}')\delta(t - t') \tag{27.100}$$

where $\langle\rangle$ denotes ensemble average and $\delta(x)$ is the Dirac delta function. Equation 27.100 is not suited for a numerical evaluation, because in dependence on the carrier densities the inversion (or spontaneous emission) factor n_{sp} has a singularity when the gain g changes its sign (transparency) so that the product $g \cdot n_{\mathrm{sp}}$ is undefined. One possibility to circumvent this is to take the second moment (Equation 27.100) proportional to $\beta_{\mathrm{sp}}R_{\mathrm{sp}}$ where R_{sp} given in Equation 27.139 is the rate of spontaneous emission into all modes and the dimensionless factor β_{sp} is chosen such that at threshold the correct values of the second moments are obtained [8].

27.4.3 Final Field Equation and Balance of Radiative Energy

Summarizing the results of the previous subchapter, the paraxial wave equation can be written as

$$\begin{aligned}\frac{1}{v_\mathrm{g}}\partial_t E^{\pm}(\boldsymbol{r}, t) \pm \partial_z E^{\pm}(\boldsymbol{r}, t) = &-\frac{i}{2\bar{n}k_0}\left(\partial_{xx} + \partial_{yy}\right)E^{\pm}(\boldsymbol{r}, t)\\ &- \frac{ik_0}{2\bar{n}}\Delta n^2(\boldsymbol{r}, t)E^{\pm}(\boldsymbol{r}, t) - \frac{n_\mathrm{r}(\boldsymbol{r}, t)g_\mathrm{r}(\boldsymbol{r}, t)}{2\bar{n}}\left[E^{\pm}(\boldsymbol{r}, t) - \mathcal{P}^{\pm}(\boldsymbol{r}, t)\right]\\ &- \frac{ik_0 n_\mathrm{r}(\boldsymbol{r}, t)}{\bar{n}}\Delta\tilde{n}_2(\boldsymbol{r}, t)\left[|E^{+}|^2 + |E^{-}|^2\right]E^{\pm}(\boldsymbol{r}, t) + F^{\pm}_{\mathrm{sp}}(\boldsymbol{r}, t)\end{aligned} \tag{27.101}$$

where

$$\Delta n^2(\boldsymbol{r},t) \equiv n^2(\boldsymbol{r},t,\omega_0) - \bar{n}^2 = \Delta n_{\mathrm{r}}^2 + i\frac{n_{\mathrm{r}}\,(g-\alpha)}{k_0} \tag{27.102}$$

Here Δn_{r}^2 is the real part of Δn^2, n_{r} the real part of n, g the coefficient of optical gain originating from the emission or absorption of photons due to transitions between the conduction and valence bands, and α the coefficient of absorption of photons due to transitions within the conduction and valence bands (such as free-carrier absorption and intervalence band absorption). Optical losses due to scattering on waveguide imperfections could be included in α, too.

Multiplying Equation 27.101 with the complex conjugate $E^{\pm *}$, multiplying the complex conjugate of Equation 27.101 with $E^{\pm}$ and adding all equations results in

$$\begin{aligned}\frac{1}{v_{\mathrm{g}}}\frac{d\|E\|^2}{dt} = {}& \frac{1}{\bar{n}k_0}\mathrm{Im}\left[\partial_x(E^{+*}\partial_x E^{+} + E^{-*}\partial_x E^{-}) + \partial_y(E^{+*}\partial_y E^{+} + E^{-*}\partial_y E^{-})\right] \\ & + \partial_z\left[|E^{-}|^2 - |E^{+}|^2\right] \\ & + \frac{n_{\mathrm{r}}(g-\alpha)}{\bar{n}}\|E\|^2 + \frac{n_{\mathrm{r}}g_{\mathrm{r}}}{\bar{n}}\left[\mathrm{Re}(E^{+*}\mathcal{P}^{+} + E^{-*}\mathcal{P}^{-}) - \|E\|^2\right] \\ & - \frac{n_{\mathrm{r}}\tilde{\beta}}{\bar{n}}\|E\|^4 + 2\mathrm{Re}(E^{+*}F_{\mathrm{sp}}^{+} + E^{-*}F_{\mathrm{sp}}^{-})\end{aligned} \tag{27.103}$$

with $\|E\|^2 = |E^{+}|^2 + |E^{-}|^2$. This equation can be interpreted as a balance equation for the radiative energy density

$$u_{\mathrm{rad}}(\boldsymbol{r},t) = \frac{\varepsilon_0\bar{n}n_{\mathrm{g}}}{2}\|E(\boldsymbol{r},t)\|^2 \tag{27.104}$$

Integrating Equation 27.103 over the device volume V and using the boundary conditions Equations 27.88 and 27.87 leads to

$$\begin{aligned}\frac{\mathrm{d}\int_V u_{\mathrm{rad}}\,\mathrm{d}V}{\mathrm{d}t} = {}& -P_{\mathrm{out}} + \frac{\varepsilon_0 c}{2}\int_V n_{\mathrm{r}}(g - g_{\mathrm{r}} - \alpha)\|E\|^2\,\mathrm{d}V \\ & + \frac{\varepsilon_0 c}{2}\int_V n_{\mathrm{r}}g_{\mathrm{r}}\left[\mathrm{Re}(E^{+*}\mathcal{P}^{+} + E^{-*}\mathcal{P}^{-})\right]\mathrm{d}V - \frac{\varepsilon_0 c}{2}\int_V n_{\mathrm{r}}\tilde{\beta}\|E\|^4\,\mathrm{d}V \\ & + \frac{\varepsilon_0 c}{\bar{n}}\int_V \mathrm{Re}(E^{+*}F_{\mathrm{sp}}^{+} + E^{-*}F_{\mathrm{sp}}^{-})\,\mathrm{d}V\end{aligned} \tag{27.105}$$

which is a generalization of Equation 27.31. The output power $P_{\mathrm{out}} = P_0 + P_L$ is given in Equation 27.30 where $R_0 = |r_0|^2$ and $R_L = |r_L|^2$. The optical power is

$$P^{\pm}(z) = \frac{\varepsilon_0\bar{n}c}{2}\iint |E^{\pm}(x,y,z)|^2\,\mathrm{d}x\mathrm{d}y. \tag{27.106}$$

Thus the first term in Equation 27.103 is the divergence of the transverse energy flux density, which is assumed to vansish on the transverse surface of the device. The second term gives the radiation leaving the cavity. The third and fourth terms describe the increase or decrease of the energy due to stimulated emission or absorption, respectively, and the last two terms due to two-photon absorption and spontaneous emission.

27.4.4 Cavity Modes, Beam Propagation Method, and Roundtrip Operator

The cavity modes are time-periodic solutions of the form $E^{\pm}_{\mathrm{m}}\exp(i\Omega_{\mathrm{m}}t)$, $\mathcal{P}^{\pm}\exp(i\Omega_{\mathrm{m}}t)$ and obey the linear equations

$$\pm\, i\partial_z E^{\pm}_{\mathrm{m}}(\boldsymbol{r}) = \left[\frac{\Omega_{\mathrm{m}}}{v_{\mathrm{g}}} + \mathbf{H}(\boldsymbol{r}, z)\right] E^{\pm}_{\mathrm{m}}(\boldsymbol{r}) \tag{27.107}$$

subject to the boundary conditions (Equations 27.87 and 27.88). The operator **H** is given by

$$\mathbf{H}(\boldsymbol{r}, z) = \frac{1}{2\bar{n}k_0}\left(\partial_{xx} + \partial_{yy}\right) + \frac{k_0}{2\bar{n}}\Delta n^2(\boldsymbol{r}) + i\frac{n_{\mathrm{r}}(\boldsymbol{r})g_{\mathrm{r}}(\boldsymbol{r})}{2\bar{n}}\left[\frac{\gamma(\boldsymbol{r})}{i\Omega_{\mathrm{m}} - i(\omega_{\mathrm{p}}(\boldsymbol{r}) - \omega_0) + \gamma(\boldsymbol{r})} - 1\right] \tag{27.108}$$

The nontrivial solutions of (Equation 27.107) may depend on time via the dependence of the complex-valued refractive index on temporally varying carrier densities and temperature. The complex-valued relative mode frequencies Ω_{m} are the eigenvalues and the mode profiles $E^{\pm}_{\mathrm{m}}$ are the eigenfunctions of Equation 27.107. The real parts of Ω_{m} give the wavelengths relative to the reference wavelength λ_0,

$$\Delta\lambda_m = \left.\frac{\mathrm{d}\lambda}{\mathrm{d}\omega}\right|_{\lambda_0} \mathrm{Re}(\Omega_{\mathrm{m}}) \tag{27.109}$$

and the imaginary parts describe the damping of the modes. For a passive cavity, $\mathrm{Im}(\Omega_{\mathrm{m}}) > 0$ must hold. Lasing modes of an active cavity are distinguished by vanishing damping, $\mathrm{Im}(\Omega_{\mathrm{m}}) = 0$, due to the balance of the outcoupling and internal losses and the gain.

It can be shown that the cavity modes fulfil an orthogonality relation which does not define a scalar product because of the non-Hermitian character of Equation 27.107. Due to the dispersion term in Equation 27.107 the orthogonality relation differs from that given in [6], but can be derived in the same manner.

If the operator **H** depends only on the transverse coordinates $\boldsymbol{r}_{\mathrm{t}}$, the solution of Equation 27.107 can be formally written as

$$E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z') = \mathrm{e}^{\mp i(\frac{\Omega_{\mathrm{m}}}{v_{\mathrm{g}}} + \mathbf{H})(z'-z)} E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z) \tag{27.110}$$

The numerical evaluation of Equation 27.110 is the basis of what is known as the beam propagation method (BPM) [45–47]. For the case of a spatially and temporally constant index, $n = \text{const.}$, Equation 27.110 can be evaluated exactly to yield

$$E^{\pm}_{\mathrm{m}}(\boldsymbol{r}'_{\mathrm{t}}, z') = \mathrm{e}^{\mp i(\frac{\Omega_{\mathrm{m}}}{v_{\mathrm{g}}} + \frac{k_0}{2\bar{n}}\Delta n^2)(z'-z)} \int G^{\pm}(\boldsymbol{r}'_{\mathrm{t}} - \boldsymbol{r}_{\mathrm{t}}, z' - z) E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z)\, \mathrm{d}x\mathrm{d}y \tag{27.111}$$

with

$$G^{\pm}(\boldsymbol{r}'_{\mathrm{t}} - \boldsymbol{r}_{\mathrm{t}}, z' - z) = \Theta\big(\pm (z' - z)\big)\left[\sqrt{\pm\frac{i\bar{n}k_0}{2\pi(z' - z)}}\right]^2 \mathrm{e}^{\mp\frac{i\bar{n}k_0|\boldsymbol{r}'_{\mathrm{t}} - \boldsymbol{r}_{\mathrm{t}}|^2}{2(z'-z)}} \tag{27.112}$$

where Θ denotes the Heaviside step function. The integral equation (Equation 27.111) together with the propagator Equation 27.112 is known as Huygen's integral in the Fresnel approximation.

Based on Equation 27.110 and the boundary conditions (Equation 27.87), it is possible to construct roundtrip operators $\mathbf{M}^{\pm}$. One starts at some position $z = z_0$ within the cavity and performs a full roundtrip. Depending on whether we start into forward (+) or backward (−) directions, the eigenvalue problems

$$\mathbf{M}^{\pm}(\Omega_{\mathrm{m}})E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z_0) = \mathrm{e}^{i\frac{2\Omega_{\mathrm{m}}}{v_{\mathrm{g}}}L} E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z_0) \tag{27.113}$$

are obtained. Note that the roundtrip operators $\mathbf{M}^{\pm}$ depend on the eigenvalues Ω_{m} if dispersion is taken into account. The eigenfunctions of $\mathbf{M}^{\pm}$ are the mode distributions $E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z_0)$ at the position z_0. A very popular method for solving Equation 27.113 is based on the Fox–Li approach, cf. [48] and the references therein. The idea is to choose a normalized, more or less arbitrary start distribution $E^{\pm}_{\mathrm{m}}(\boldsymbol{r}_{\mathrm{t}}, z_0)$ and to apply the roundtrip operator $\boldsymbol{M}^{\pm}$ recurrently until one arrives (hopefully) at a steady state. It is known that the algorithm fails if there are cavity modes having identical or nearly identical damping $\mathrm{Im}(\Omega_{\mathrm{m}})$, as it is the case in broad-area lasers. The association of the nonconvergence of the Fox–Li iteration with an dynamically unstable laser behavior should be done with care. Instead, for multimode high-power lasers, a time-dependent approach based on Equation 27.101 should be preferred, although it is numerically more challenging.

27.5 Models for Nonlinear Modes and Filamentation

The multipeaked and not diffraction-limited lateral field profile of wide-aperture semiconductor lasers has been a long-standing problem and has been investigated in the past by numerous authors [49–55]. Although the broadening of the far field of CW operating lasers with increasing power (also called far-field blooming) can be at least partially attributed to the thermal lensing effect [56–58], a complete picture of the origin and mechanism has not revealed yet.

One mechanism is believed to be due to carrier-induced antiguiding, i.e., the reduction of the refractive index with increasing carrier density. This leads to a self-focusing mechanism because the index increases in regions of high intensity due to a depletion of the injected carrier density and can result in the formation of what is sometimes called lasing filaments.

Another mechanism that could explain the multipeaked structure and the broadening of the farfield is the simultaneous lasing of a large number of waveguide modes, originating from a built-in or thermally induced waveguide. Indeed, recent experiments reveal, that even at currents several times above threshold the lateral modes can be clearly identified by spectrally resolved near- and far-field measurements [58,59]. However, with increasing current, a broadening of the individual modes and the appearance of new modes with broad near and far fields can be observed [60].

Here, we derive the equation for the description of the lateral field profile and discuss two basic nonlinearities due to the virtual transitions and due to lateral spatial hole burning.

27.5.1 Longitudinal–Lateral Approximate Projected Equations

First we project the basic equations onto the dominant vertical mode using the Ansatz

$$E^{\pm}(\boldsymbol{r}, t) = \sqrt{\frac{2d\hbar\omega_0}{\varepsilon_0 \bar{n} n_{\mathrm{g}}}}\,\phi(y, x, z)u^{\pm}(x, z, t) \tag{27.114}$$

where the mode profile $\phi(y, x, z)$ is normalized according to $\int |\phi|^2\, dy = 1$. The scaling in Equation 27.114 is chosen such that $|u^{\pm}|^2$ is a photon density (unit m^{-3}). The power is given by

$$P^{\pm} = \hbar\omega_0 v_{\mathrm{g}} d \int |u^{\pm}|^2\, dx \tag{27.115}$$

where d is the thickness of the active region.

For each (x, z), $\phi(y, x, z)$ is a solution of a vertical waveguide equation with a real-valued index profile n_0 not dependent on carrier densities and temperature,

$$\partial_{yy}\phi(x, y, z) + k_0^2 n_0^2(x, y, z)\phi(x, z, y) = k_0^2 n_{\mathrm{eff},0}^2(x, z)\phi(x, y, z) \tag{27.116}$$

where the real-valued effective index $n_{\mathrm{eff},0}$ is the eigenvalue of Equation 27.116. Inserting Equation 27.114 into Equation 27.101, multiplying with ϕ, and integrating along y yields the equations

$$\begin{aligned} \frac{1}{v_{\mathrm{g}}}\partial_t u^{\pm}(x, z, t) = {} & -\frac{i}{2\bar{n}k_0}\partial_{xx}u^{\pm}(x, z, t) \mp \partial_z u^{\pm}(x, z, t) - \frac{ik_0}{2\bar{n}}\left[n_{\mathrm{eff}}^2(x, z, t) - \bar{n}^2\right] u^{\pm}(x, z, t) \\ & - ik_0 \Delta n_{2,\mathrm{eff}}(x, z, t)\hbar\omega_0 v_{\mathrm{g}} d \|u(x, z, t)\|^2 u^{\pm}(x, z, t) \end{aligned} \tag{27.117}$$

where we omitted the dispersion and spontaneous emission terms for simplicity and

$$n_{\mathrm{eff}}^2 = n_{\mathrm{eff,r}}^2 + i\frac{\bar{n}\left(g_{\mathrm{eff}} - \alpha_{\mathrm{eff}}\right)}{k_0}, \tag{27.118}$$

$$n_{\mathrm{eff,r}}^2 = n_{\mathrm{eff},0}^2 + \int (n_{\mathrm{r}}^2 - n_0^2)|\phi|^2\, \mathrm{d}y, \tag{27.119}$$

$$g_{\mathrm{eff}} - \alpha_{\mathrm{eff}} = \frac{\int n_{\mathrm{r}}(g - \alpha)|\phi|^2\, \mathrm{d}y}{\bar{n}} \tag{27.120}$$

and

$$\Delta n_{2,\mathrm{eff}} = \frac{\int n_{\mathrm{r}} \Delta n_2 |\phi|^4\, dy}{\bar{n}} \approx \frac{\Delta \bar{n}_2}{d_{1/e^2}} \tag{27.121}$$

The second term in Equation 27.119 treats effects, which are not included in n_0 and thus $n_{\mathrm{eff},0}$, for example, the dependence of the real and imaginary parts of n_{r} on the carrier densities or the temperature. The vertical mode size d_{1/e^2} has been introduced in Equation 27.68. The approach sketched is called the "effective index method" in the semiconductor laser community. Inserting Equation 27.114 into the rate of stimulated recombination Equation 27.140 and averaging over the active region $1/d \int_0^d\, dy$ yields

$$R_{\mathrm{st}} = v_{\mathrm{g}}\, g_{\mathrm{eff}} \|u\|^2 \tag{27.122}$$

with $\|u\|^2 = |u^+|^2 + |u^-|^2$.

Equation 27.117 together with correspondingly projected equations for the polarization (Equation 27.94) and a lateral diffusion equation for the excess carriers have been successfully applied to the simulation of a large variety of high-power laser structures [61–66]. A discussion on numerical issues can be found in [67].

27.5.2 Nonlinearities due to Virtual Transitions

The energy gaps of the confinement and cladding layers of a laser structure are larger than the energy of the photons generated by stimulated emission. In this situation, the photon energy is too small to allow absorption of single-photons due to transitions of electrons between the valence and conduction bands, as intended. However, virtual transitions involving two photons are still possible, which result in a third-order susceptibility defined in Equation 27.96. An approximate expression for the dispersion of the two-photon absorption coefficient β for direct transitions has been given in [68]:

$$\beta(\omega) = K\frac{\sqrt{E_{\mathrm{p}}}}{n_{\mathrm{r}}^2 E_{\mathrm{g}}^3} F_2\left(\frac{\hbar\omega}{E_{\mathrm{g}}}\right) \tag{27.123}$$

where E_{p} is the energy equivalent of the momentum matrix element for direct transitions between the valence and conduction bands, E_{g} is the (direct) energy gap and

$$F_2(x) = \frac{(2x-1)^{1.5}}{(2x)^5} \quad \text{for} \quad 2x > 1 \tag{27.124}$$

The factor K can be considered to be a free parameter. The two-photon absorption coefficient $\beta = 260$ m/TW experimentally determined for GaAs at a wavelength of $\lambda = 1064$ nm [44] is obtained with $K = 41,200\ \mathrm{m/TW} \times \mathrm{eV}^3/\sqrt{\mathrm{eV}}$, using $E_{\mathrm{g}} = 1.42$ eV, $E_{\mathrm{p}} = 26.1$ eV, and $n_{\mathrm{r}} = 3.48$. Note the E_{g}^{-3} dependence of β.

Two-photon absorption as well as Raman and Stark effects result also in an intensity-dependent contribution to the real part of the refractive index expressed as the optical Kerr coefficient n_2,

$$n_2(\omega) = \tilde{K}\frac{\hbar c\sqrt{E_{\mathrm{p}}}}{2n_{\mathrm{r}}^2 E_{\mathrm{g}}^4} G_2\left(\frac{\hbar\omega}{E_{\mathrm{g}}}\right) \tag{27.125}$$

where the function $G_2(\hbar\omega/E_{\mathrm{g}})$ given in [68] is shown in Figure 27.11 together with the function $F_2(\hbar\omega/E_{\mathrm{g}})$. It can be seen, that G_2 is maximal around $\hbar\omega = 0.5E_{\mathrm{g}}$ and changes its sign at $\hbar\omega = 0.7E_{\mathrm{g}}$, where F_2 is

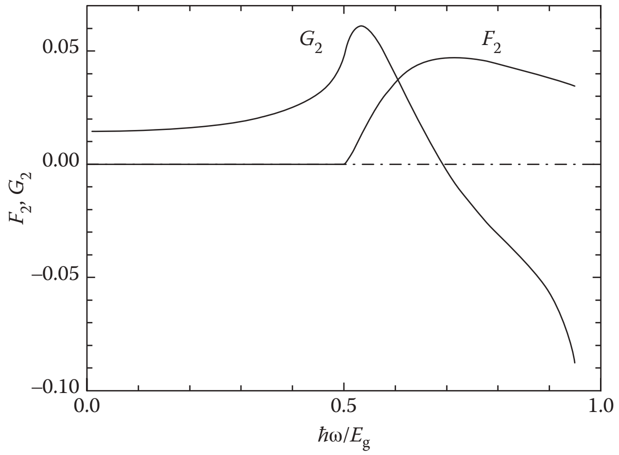


FIGURE 27.11 Functions F_2 and G_2 used in Equations 27.123 and 27.125.

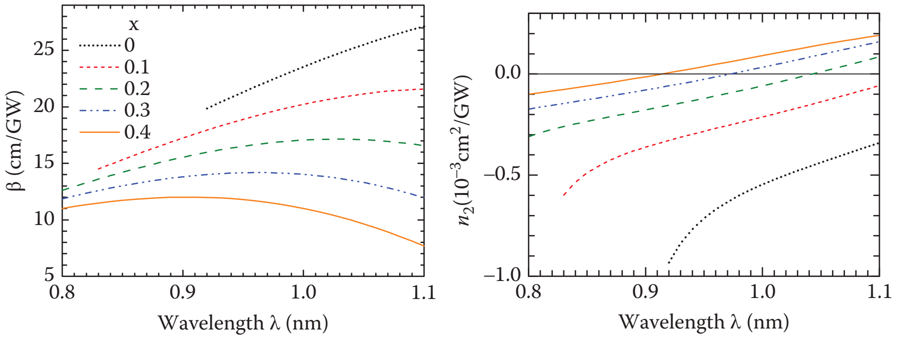


(a)

(b)

FIGURE 27.12 Nonlinear coefficients calculated by Equations 27.123 and 27.125 versus wavelength for different Al compositions x in $\text{Al}_x\text{Ga}_{1-x}\text{As}$. (a) Two-photon absorption coefficient and (b) Optical Kerr coefficient.

maximal[†]. The factor $\tilde{K}$ can again be considered as a free parameter. The optical Kerr coefficient $n_2 = -4.1 \cdot 10^{-17}$ m/W experimentally determined for GaAs at a wavelength of $\lambda = 1064$ nm [44] is obtained with $\tilde{K} = 7.212 \cdot 10^{11}\ \text{m/W} \times 1/(\text{Ws m}) \times \text{eV}^4/\sqrt{\text{eV}}$.

The dependencies of β and n_2 of $\text{Al}_x\text{Ga}_{1-x}\text{As}$ on λ are shown in Figure 27.12a and 27.12b, respectively. The two-photon absorption increases from $\beta \propto 10$ cm/GW to $\beta \propto 25$ cm/GW if the Al composition is decreased from $x = 0.4$ to $x = 0$ due to the decrease of E_g. It shows a nonmonotonous dependence on the wavelength given by $F_2(\lambda)$. The optical Kerr coefficient decreases with increasing x and changes its sign in dependence on λ at higher Al compositions within the wavelength range investigated. For smaller Al compositions and wavelengths n_2 is negative, but for larger Al compositions and wavelengths n_2 is positive. For $\lambda = 980$ nm and relevant compositions $|n_2| < 2 \cdot 10^{-4}\ \text{cm}^2/\text{GW}$. Under CW operation, the maximum power density of broad-area lasers, which are state of the art during the writing of the book is of the order $10^{-2}\ \text{GW/cm}^2$. Hence the resulting index change $|\Delta n| < 4 \cdot 10^{-6}$ should not have a big impact on the optical field.

It should be noted that in nonisotropic media the relation between the nonlinear polarization and the electric field is more complicated than given in Equation 27.95. Hence the two-photon absorption and the optical Kerr effect depend on the crystallographic orientation and on the polarization direction of the optical field.

27.5.3 Nonlinearity Induced by Lateral Spatial Hole Burning

We now derive equations for the right and left traveling fields alone, eliminating the carrier density. This is only possible for a (hypothetical) steady state. To this end, the real and imaginary parts of Δn_{eff}^2 are linearized around a reference carrier density N_{ref}, which is typically set to the transparency carrier density N_{tr} were $g_{\text{eff}}(N_{\text{tr}}) = 0$. Other possible choices could be the carrier density for waveguide transparency (solution of $g_{\text{eff}}(N_{\text{ref}}) = \alpha_{\text{eff}}$) or the threshold carrier density of a laterally infinite laser (solution of $g_{\text{eff}}(N_{\text{thr}}) = \alpha_{\text{eff}} + \alpha_{\text{out}}$).

For the steady state, linearizing the recombination rate as in Section 27.3.2, neglecting drift-diffusion, and assuming a constant injection current density the rate equation can be solved for the excess carrier density,

---

[†] The functions F_2 and G_2 due to indirect transitions behave differently [69]: The maximum of F_2 occurs slightly above the indirect bandgap, and G_2 is positive throughout the transparent wavelength range and crosses zero only above the indirect gap. The two-photon absorption coefficient is dominated by direct transitions for $\hbar\omega > E_{\text{g,direct}}/2$ if $E_{\text{g,indirect}} > E_{\text{g,direct}}/2$.

$$N - N_{\mathrm{tr}} = \frac{\frac{j\tau_N}{ed} - N_{\mathrm{tr}}}{1 + v_{\mathrm{g}} g'_{\mathrm{eff}} \tau_N \|u_{\mathrm{s}}\|^2}. \tag{27.126}$$

From Equation 27.126 it can be seen that $N \to N_{\mathrm{tr}}$ for $\|u_{\mathrm{s}}\|^2 \to \infty$, i.e., the carrier density cannot be depleted below the transparency carrier density. Inserting Equation 27.126 into $\Delta n^2_{\mathrm{eff,r}}(N)$, $g_{\mathrm{eff}}(N)$, and $\alpha_{\mathrm{eff}}(N)$ yields

$$g_{\mathrm{eff}}(j) = \frac{g'_{\mathrm{eff}} \tau_N (j - j_{\mathrm{tr}})}{ed(1 + \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2)}, \tag{27.127}$$

$$\alpha_{\mathrm{eff}}(j) = \alpha_{\mathrm{eff}}(N_{\mathrm{tr}}) + \frac{\alpha'_{\mathrm{eff}} \tau_N (j - j_{\mathrm{tr}})}{ed(1 + \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2)}, \tag{27.128}$$

$$n^2_{\mathrm{eff,r}}(j) = n^2_{\mathrm{eff,r}}(N_{\mathrm{tr}}) + \frac{\alpha_{\mathrm{H}} \bar{n} g'_{\mathrm{eff}} \tau_N (j - j_{\mathrm{tr}})}{edk_0(1 + \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2)} \tag{27.129}$$

with the saturation parameter

$$\epsilon_{\mathrm{sat}} = v_{\mathrm{g}} g'_{\mathrm{eff}} \tau_N \tag{27.130}$$

and Henry's α-factor

$$\alpha_{\mathrm{H}} = 2k_0 n'_{\mathrm{eff}} / g'_{\mathrm{eff}}. \tag{27.131}$$

For typical values $n_{\mathrm{g}} = 4$, $g'_{\mathrm{eff}} = 10 \cdot 10^{-18}\ \mathrm{cm}^2$, and $\tau_N = 1$ ns we obtain $\varepsilon_{\mathrm{sat}} = 7.5 \cdot 10^{-17}\ \mathrm{cm}^3$. In general, $g'_{\mathrm{eff}} > 0$ and $n'_{\mathrm{eff}} < 0$ and hence $\alpha_{\mathrm{H}} < 0$ for frequencies around the gain peak. Typical values of α_{H} range from -1 to -10.

The stationary states correspond to time-harmonic solutions

$$u^{\pm}(x, z, t) = u^{\pm}_{\mathrm{s}}(x, z) e^{i\Omega t} \tag{27.132}$$

of Equation 27.117 with $\mathrm{Im}(\Omega) = 0$. Inserting Equations 27.132, 27.127, and 27.129 into Equation 27.117, we obtain

$$\begin{aligned} \pm i\partial_z u^{\pm}_{\mathrm{s}} = {} & \frac{1}{2\bar{n}k_0} \partial_{xx} u^{\pm}_{\mathrm{s}}(x, z, t) + \frac{\Omega}{v_{\mathrm{g}}} u^{\pm}_{\mathrm{s}} + \frac{k_0}{2\bar{n}} \left[n^2_{\mathrm{eff,r}}(N_{\mathrm{tr}}) - \bar{n}^2 \right] u^{\pm}_{\mathrm{s}} - \frac{i}{2} \alpha_{\mathrm{eff}}(N_{\mathrm{tr}}) u^{\pm}_{\mathrm{s}} \\ & + \frac{\tau_N \left[(i + \alpha_{\mathrm{H}}) g'_{\mathrm{eff}} - i\alpha'_{\mathrm{eff}} \right] \left(j - j_{\mathrm{tr}} \right)}{2ed(1 + \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2)} u^{\pm}_{\mathrm{s}} + k_0 \Delta n_{2,\mathrm{eff}} \hbar\omega_0 v_{\mathrm{g}} d \|u_{\mathrm{s}}\|^2 u^{\pm}_{\mathrm{s}} \end{aligned} \tag{27.133}$$

For $\varepsilon_{\mathrm{sat}} \|u\|^2 \ll 1$ we can expand

$$(1 + \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2)^{-1} \approx 1 - \epsilon_{\mathrm{sat}} \|u_{\mathrm{s}}\|^2 \tag{27.134}$$

so that the second-last term in Equation 27.133 resembles the last term with

$$\Delta n_{2,\mathrm{SHB}} = - \frac{\tau_N \left[(\alpha_{\mathrm{H}} + i) g'_{\mathrm{eff}} - i\alpha'_{\mathrm{eff}} \right] \left(j - j_{\mathrm{tr}} \right) \epsilon_{\mathrm{sat}}}{2ek_0 \hbar\omega_0 v_{\mathrm{g}} d^2} \tag{27.135}$$

For typical values $\alpha_H = -2$, $g'_{\text{eff}} = 10 \cdot 10^{-18}\ \text{cm}^2$, $j = 10\ \text{kA/cm}^2$, $d = 10\ \text{nm}$, $\tau_N = 1\ \text{ns}$, $j_{\text{tr}} = 0.16\ \text{kA/cm}^2$ (corresponding to $N_{\text{tr}} = 10^{18}\ \text{cm}^{-3}$), $\lambda_0 = 1\ \mu\text{m}$, $n_g = 4$, $\varepsilon_{\text{sat}} = 75 \cdot 10^{-18}\ \text{cm}^3$ we obtain $\text{Real}(\Delta n_{2,\text{SHB}}) = 5 \cdot 10^{-4}\ \text{cm/W}$, which is several orders of magnitudes larger than the absolute value of the effective optical Kerr coefficient due to non-resonant virtual transitions $\text{Real}(\Delta n_{2,\text{eff}}) \approx -7 \cdot 10^{-10}\ \text{cm/W}$ for $\bar{n}_2 = -10^{-13}\ \text{cm}^2/\text{W}$ (cf. Figure 27.12b) and $d_{1/e^2} = 1.5\ \mu\text{m}$ (cf. Equation 27.121).

Due to the fact that $\text{Real}(\Delta n_{2,\text{SHB}})$ is positive, two basic instabilities sometimes termed “filamentation” arise [44]. First, a local intensity maximum induces a variation of the real part of the effective index with a larger value at the position of the intensity peak than outside. Thus a local index waveguide is created (self-focusing) [49]. However, at the position of the intensity peak the effective gain is decreased which results in an reduced amplification in the local-waveguide core and an enhanced amplification outside (self-defocusing).

The other instability, first described by Bespalov and Talanov [70], is the breakup of a laser beam with a homogeneous intensity distribution into a beam with a random intensity distribution as a consequence of the growth of irregularities initially present on the laser wavefront. For a mathematical description of the effect, the forward and backward propagating waves have to be expressed as a sum of three plane-wave components each [44,71].

In [51,72] the mean-field approximation, $\bar{u}_s^{\pm} = 1/L \int_0^L u_s^{\pm}\, dz$ has been applied to Equation 27.133 and the resulting nonlinear second-order ordinary differential equation has been solved numerically. In both references, the case of a purely gain-guided laser is considered, i.e., any impact of a built-in or thermally induced index guide has not been investigated. In [72], a zoo of solutions of different types, including asymmetric ones, has been found. The basic stationary states are the linear modes with the wavelengths

$$\Delta\lambda_{\nu k} = -\frac{\lambda_0}{Lk_0 n_g}\left[\frac{\varphi_0 + \varphi_L}{2} + \pi k - Lk_0\bar{n} - \frac{Lk_0}{2\bar{n}}\text{Re}(n_\nu^2 - \bar{n}^2)\right] \tag{27.136}$$

where k denotes the longitudinal mode, n_ν is the modal index of the νth lateral mode, φ_0 and φ_L are the phases of the reflectivities. The other types of modes exist only due to the nonlinearity in the complex effective index and arise above the thresholds of the linear-guided modes.

There are a number of shortcomings of the theory presented so far. The assumption of a constant injection current density, i.e., an infinite series resistance as in Section 27.3.2 discussed, and the neglect of drift-diffusion result in an overestimation of spatial hole burning. A local variation of the complex effective index is not only caused by its dependence on the carrier density but also on the temperature ($\partial n/\partial T > 0$). Furthermore, in all analytical investigations, we are aware of no built-in or thermally induced index waveguides have been taken into account. These waveguides stabilize the linear guided modes, which are thus observable even far above threshold [60].

Based on an expansion of the optical field on the linear-guided modes and a numerical solution of the drift-diffusion equations in the mean-field approximation the far-field blooming of an index-guided broad-area laser has been investigated in [73]. The simulations revealed that a substantial part of the far-field blooming is not caused by self-heating but by increasing gain nonuniformity due to lateral spatial holeburning and laterally varying hole injection into the QWs. A discussion of filamentation effects based on a numerical solution of Equation 27.117 can be found in [53–55].

27.6 Thermodynamic-Based Energy-Transport Model

In high-power lasers operated in CW mode the transport of the charged carriers (electrons and holes) and the photons must be consistently formulated with the temperature flow in order to describe self-heating effects such as thermal roll-over and thermal lensing properly. A derivation of such a self-consistent energy-transport model by applying fundamental thermodynamic principles has been given in [74] using Boltzmann statistics. The model fulfils the first and second laws of thermodynamics as well as Onsager's reciprocity relations for the current densities. We note, that in this model electron, hole, and lattice temperatures are assumed to be equal, opposed to other energy-transport models [29,75]. A more general energy-transport model for semiconductor devices has been derived in [76] taking into account Fermi statistics and different temperatures for the charged carriers and the lattice, but disregarding optical fields. Previous formulations have been also given in [77,78], for example. In what follows we will summarize the energy-transport model paying particular attention to a consistent formulation with the model for the optical field presented in Section 27.4.

27.6.1 Basic Equations

The particle current flow is governed by the continuity equations for electrons and holes,

$$\nabla \boldsymbol{j}_n = +e\left(R + \partial_t n\right) \tag{27.137}$$

$$\nabla \boldsymbol{j}_p = -e\left(R + \partial_t p\right) \tag{27.138}$$

were $\boldsymbol{j}_n$ and $\boldsymbol{j}_p$ are the current densities for electrons and holes, respectively. The recombination rate R given in Equation 27.46 consists of nonradiative recombination $R_{\text{non-rad}}$, radiative spontaneous recombination R_{sp}, and radiative stimulated recombination R_{st}. The rate of radiative spontaneous recombination is often written as

$$R_{\text{sp}} = B(np - n_0 p_0) \tag{27.139}$$

with the equilibrium electron and hole densities n_0 and p_0, respectively. In the case of Boltzmann statistics, the coefficient B is constant whereas in the general case of Fermi statistics B decreases with increasing carrier densities.

The rate of stimulated recombination is the rate by which the energy density of the optical field changes by stimulated emission or absorption of a photon due to transitions between the conduction and valence bands, divided by the energy of the emitted or absorbed photon and follows from Equations 27.104 and 27.103 to

$$R_{\text{st}} = \frac{\varepsilon_0 c n_{\text{r}}}{2\hbar\omega_0}\left[g\|E\|^2 + g_{\text{r}} \sum_{\nu=+,-} \text{Re}\left(E^{\nu *}\mathcal{P}^{\nu} - E^{\nu *}E^{\nu}\right)\right] \tag{27.140}$$

The electrostatic field itself is affected by the charge distribution of mobile (n and p) and fixed (n_{A} and p_{D}) carrier densities. The corresponding electrostatic potential φ solves the Poisson equation

$$-\nabla(\varepsilon_0\varepsilon_{\text{s}}\nabla\varphi) = e(p - n + p_{\text{D}} - n_{\text{A}}) \tag{27.141}$$

with the relative static dielectric constant ε_{s}. For parabolic bands the relations between quasi-Fermi potentials φ_n and φ_p, electrostatic potential φ and carrier densities n and p are given by Equation 27.59.

In what follows we introduce the entropies per particle[†]

$$s_n = k_B \left[1 + R_n - \frac{\partial_T E_c}{k_B} + \frac{e\varphi_n + E_c - e\varphi}{k_B T}\right] \tag{27.142}$$

$$s_p = k_B \left[1 + R_p + \frac{\partial_T E_v}{k_B} - \frac{e\varphi_p + E_v - e\varphi}{k_B T}\right] \tag{27.143}$$

and the energies per particle

$$u_n = k_B T R_n - T\partial_T E_c + E_c = T(s_n - k_B) + e(\varphi - \varphi_n) \tag{27.144}$$

$$u_p = k_B T R_p + T\partial_T E_v - E_v = T(s_p - k_B) + e(\varphi_p - \varphi) \tag{27.145}$$

The functions R_n and R_p are given by the temperature derivatives of the inverse Fermi integrals,

$$R_n = -k_B T \partial_T \mathcal{F}_i^{\text{inv}}\left(\frac{n}{N_c}\right) \tag{27.146}$$

$$R_p = -k_B T \partial_T \mathcal{F}_i^{\text{inv}}\left(\frac{p}{N_v}\right) \tag{27.147}$$

For the bulk case ($i = 1/2$), Boltzmann statistics, parabolic bands, and temperature-independent electron and holes masses R_n and R_p are equal to $3/2$.

The electron and hole current densites are given by

$$\boldsymbol{j}_n = -\sigma_n(\nabla\varphi_n - P_n \nabla T) \tag{27.148}$$

$$\boldsymbol{j}_p = -\sigma_p(\nabla\varphi_p + P_p \nabla T) \tag{27.149}$$

where σ_n and σ_p are the electrical conductivities and P_n and P_p are the Seebeck coefficients or thermoelectric powers being the entropies per particle divided by the elementary charge e,

$$P_n = \frac{s_n}{e} \quad \text{and} \quad P_p = \frac{s_p}{e} \tag{27.150}$$

If the coefficients in front of the temperature derivatives in Equations 27.148 and 27.149 are derived from the Boltzmann equation in relaxation time approximation, then the factorization $\sigma_n \cdot P_n$ and $\sigma_p \cdot P_p$ is only possible for parabolic bands and Boltzmann statistics. The same holds for the factorization of the electrical conductivities into products of carrier-density independent mobilities and carrier densities, $\sigma_n = e\mu_n \cdot n$ and $\sigma_p = e\mu_p \cdot p$. Furthermore, the magnitudes of P_n, P_p similarly as μ_n, μ_p depend on the scattering processes involved [79]. For example, if the dependence of the relaxation time on the energy is given by $\tau_0[E/(k_B T)]^r$ where r ranges typically between $-3/2$ and $+3/2$, then $R_n = R_p = 3/2+r$ in Equations 27.142 and 27.143. Thus $R_n = R_p = 3/2$ holds only for an energy-independent relaxation time. The temperature derivatives $\partial_T E_c$ and $\partial_T E_v$ of the conduction and valence band edges are often not included in the definition of the Seebeck coefficients.

According to Reference [74] the heat flow equation reads

$$c_h \partial_t T - \nabla \kappa_L \nabla T = h \tag{27.151}$$

[†] The entropies can be also written as $s_n = e\partial_T(\varphi_n)_{(n,p)} + k_B$, $s_p = -e\partial_T(\varphi_p)_{(n,p)} + k_B$, where n, p are kept constant in the differentiation.

with the thermal conductivity of the crystal lattice κ_{L}, the heat capacity

$$c_{\mathrm{h}} = c_{\mathrm{L}} + n\partial_T u_n + p\partial_T u_{\mathrm{p}} \tag{27.152}$$

with c_{L} being the heat capacity of the lattice and the heat source density

$$\begin{aligned} h = {} & \frac{k_{\mathrm{B}}T}{e}\boldsymbol{\nabla}(\boldsymbol{j}_n - \boldsymbol{j}_p) + T(\boldsymbol{j}_n\boldsymbol{\nabla}P_n - \boldsymbol{j}_p\boldsymbol{\nabla}P_p) \\ & + \frac{1}{\sigma_n}\boldsymbol{j}_n^2 + \frac{1}{\sigma_p}\boldsymbol{j}_p^2 + (u_n + u_p)R - \partial_t u_{\mathrm{rad}} - \gamma_{\mathrm{rad}} \end{aligned} \tag{27.153}$$

The first term in Equation 27.153 is related to thermodiffusion and can be written as

$$\frac{k_{\mathrm{B}}T}{e}\boldsymbol{\nabla}\cdot(\boldsymbol{j}_n - \boldsymbol{j}_p) = 2k_{\mathrm{B}}TR + k_{\mathrm{B}}T(\partial_t n + \partial_t p) \tag{27.154}$$

taking into account Equations 27.137 and 27.138. The second term describes Thomson–Peltier heat,

$$h_{\mathrm{TP}} = T(\boldsymbol{j}_n\boldsymbol{\nabla}P_n - \boldsymbol{j}_p\boldsymbol{\nabla}P_p) = h_{\mathrm{Thomson}} + h_{\mathrm{Peltier}} \tag{27.155}$$

which is generated by a current flow along the gradients of the Seebeck coefficients ∇P_n and ∇P_p. By applying the chain rule to the gradients, the contributions due to Thompson heat and Peltier heat can be separated,

$$h_{\mathrm{Thomson}} = T\boldsymbol{\nabla}T\left(\boldsymbol{j}_n\partial_T P_n|_{(n,p)} - \boldsymbol{j}_p\partial_T P_p|_{(n,p)}\right) \tag{27.156}$$

$$h_{\mathrm{Peltier}} = T\left(\boldsymbol{j}_n\partial_n P_n|_T\boldsymbol{\nabla}n - \boldsymbol{j}_p\partial_p P_p|_T\boldsymbol{\nabla}p\right) \tag{27.157}$$

The third and forth terms correspond to Joule heat:

$$h_{\mathrm{J}} = \frac{1}{\sigma_n}\boldsymbol{j}_n^2 + \frac{1}{\sigma_p}\boldsymbol{j}_p^2 \tag{27.158}$$

generated by scattering of the carriers on phonons resulting in a energy loss to the lattice. The last term is due to contributions of the recombination of electron–hole pairs which sets free the energy $u_n + u_p$ that is either transferred to the lattice as heat or transferred to the radiative field. The latter part is described by the term $\partial_t u_{\mathrm{rad}}$, which has to be subtracted from the source term, like the term γ_{rad}, which denotes the energy loss from the cavity. Inserting Equations 27.154, 27.155, and 27.158 into Equation 27.153 gives

$$h = k_{\mathrm{B}}T(\partial_t n + \partial_t p) + h_{\mathrm{TP}} + h_{\mathrm{J}} + h_{\mathrm{rec+abs}} \tag{27.159}$$

with the recombination and absorption heat

$$h_{\mathrm{rec+abs}} = e(TP_n + TP_p + \varphi_p - \varphi_n)R - \partial_t u_{\mathrm{rad}} - \gamma_{\mathrm{rad}} \tag{27.160}$$

where $R = R_{\mathrm{non\text{-}rad}} + R_{\mathrm{sp}} + R_{\mathrm{st}}$. Likewise the rate of radiative recombination, the radiative energy density u_{rad} and the radiative energy loss γ_{rad} have contributions from spontaneous and stimulated emission, $u_{\mathrm{rad}} = u_{\mathrm{sp}} + u_{\mathrm{st}}$ and $\gamma_{\mathrm{rad}} = \gamma_{\mathrm{sp}} + \gamma_{\mathrm{st}}$. Here, u_{sp} is the energy density and γ_{sp} the corresponding cavity loss of the radiation generated by spontaneous emission into all modes (i.e., spatial directions, polarization directions of the field and frequencies) not included in $E^{\pm}$ given by Equation 27.101.

The balance equation for the energy density of the radiation generated by stimulated emission is given by Equations 27.103 and 27.104. As it has been stated before the first term on the rhs of Equation 27.103 gives the divergence of the transverse energy flux density and the second term the radiation leaving the cavity in propagation direction. Both terms combined give the total stimulated-energy loss from the cavity $-\gamma_{\mathrm{st}}$,

$$\begin{aligned}-\gamma_{\mathrm{st}} = {} & \frac{\varepsilon_0 c}{2k_0}\mathrm{Im}\left[\partial_x(E^{+*}\partial_x E^{+} + E^{-*}\partial_x E^{-}) + \partial_y(E^{+*}\partial_y E^{+} + E^{-*}\partial_y E^{-})\right] \\ & + \frac{\varepsilon_0 \bar{n} c}{2}\partial_z\left[|E^{-}(r,t)|^2 - |E^{+}(r,t)|^2\right] \end{aligned} \tag{27.161}$$

and hence

$$\partial_t u_{\mathrm{st}} = \frac{\varepsilon_0 c n_{\mathrm{r}}}{2}\left((g - g_r - \alpha)\|E\|^2 + g_r \mathrm{Re}(E^{+*}\mathcal{P}^{+} + E^{-*}\mathcal{P}^{-})\right) - \frac{\varepsilon_0 c n_{\mathrm{r}}\tilde{\beta}}{2}\|E\|^4 - \gamma_{\mathrm{st}}. \tag{27.162}$$

Inserting Equations 27.162 and 27.140 into Equation 27.160 gives

$$\begin{aligned} h_{\mathrm{rec+abs}} = {} & e(\mathrm{TP}_n + \mathrm{TP}_p + \varphi_p - \varphi_n)R_{\mathrm{non\text{-}rad}} + \frac{\varepsilon_0 c n_{\mathrm{r}}\alpha}{2}\|E\|^2 + \frac{\varepsilon_0 c n_{\mathrm{r}}\tilde{\beta}}{2}\|E\|^4 \\ & + \left[e(\mathrm{TP}_n + \mathrm{TP}_p + \varphi_p - \varphi_n) - \hbar\omega_0\right] R_{\mathrm{st}} \\ & + e(\mathrm{TP}_n + \mathrm{TP}_p + \varphi_p - \varphi_n)R_{\mathrm{sp}} - \partial_t u_{\mathrm{sp}} - \gamma_{\mathrm{sp}} \end{aligned} \tag{27.163}$$

with the rate of stimulated recombination Equation 27.140. Equation 27.163 is the net heat source caused by recombination and absorption. The first term is the heat generated by nonradiative recombination. The second and third terms describe the heat due to absorption of the stimulated radiation. The fourth term is caused by a possible incomplete energy transfer from the carrier ensemble to the radiation field during stimulated emission, also referred to as quantum defect energy. The last terms describe the heat due to the absorption of the spontaneous radiation, which could be treated similarly as the stimulated radiation but approximations have to be employed because the field generated by spontaneous emission is more challenging to calculate.

27.6.2 Spatial Distributions of the Heat Sources

The profiles of the heat sources of an asymmetric super-large optical-cavity structure similar to that published in [10] are shown in Figure 27.13a through 27.13d for the steady state for an output power of $P_{\mathrm{out}} = 18$ W and an averaged internal power of $\bar{P} = 8$ W. Some of the parameters are given in Table 27.1. The one-dimensional simulation (along y) has been performed with the simulator WIAS-TeSCA [80]. The absorption heat

$$h_{\mathrm{abs}} = (f_{\mathrm{c},n} n + f_{\mathrm{c},p} p)\bar{P}\frac{|\phi|^2}{W} \tag{27.164}$$

with $\phi(y)$ being the vertical normalized mode profile is shown in Figure 27.13. The cross sections for free-carrier absorption are $f_{\mathrm{c},n} = 4 \cdot 10^{-18}$ cm^2 and $f_{\mathrm{c},p} = 12 \cdot 10^{-18}$ cm^2. The main contributions arise in the active layer located at $y \approx 1.9$ μm due to the high nonequilibrium electron and hole densities and in the adjacent p- and n-doped confinement layers where the optical mode resides. The recombination heat

$$h_{\mathrm{rec}} = (5k_{\mathrm{B}}T + E_{\mathrm{g}})\left(R_{\mathrm{non\text{-}rad}} + R_{\mathrm{sp}}\right) \tag{27.165}$$

in Boltzmann approximation is maximal in the active layer as expected. Note that the temperature dependencies of E_c and E_v were not taken into account. The recombination of leaky electrons and holes in the p-confinement layer (cf. Figure 27.10b) generates heat, too. The quantum defect heat

$$h_{\text{defect}} = (5k_B T + E_g - \hbar\omega_0)\frac{g\bar{P}|\phi|^2}{\hbar\omega_0 W} \tag{27.166}$$

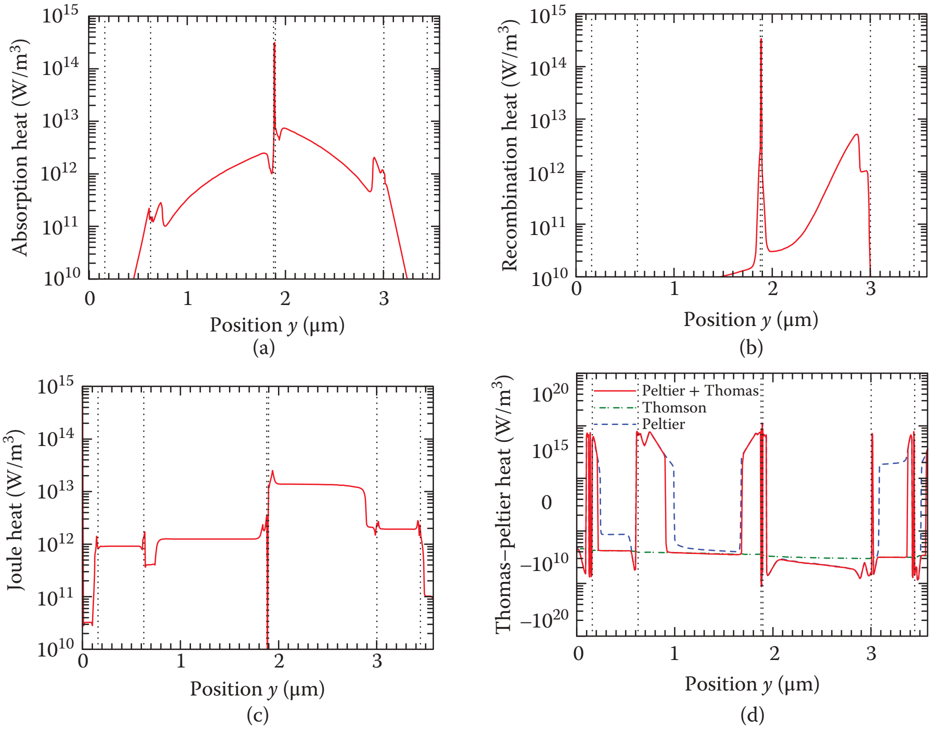
in a Boltzmann approximation, not shown here, is nonvanishing only in the active region and has the same order of magnitude like the recombination heat there ($h_{\text{defect}} \approx 8 \cdot 10^{14}$ W/m^3). The Joule heat (Equation 27.158) shown in Figure 27.13c is mainly generated in the p-confinement layer due to its low doping and the small mobility of the holes. Finally, Thomson heat

$$h_{\text{Thompson}} = \frac{3}{2}\frac{k_B}{e}\frac{dT}{dy}\left(j_{n,y} - j_{p,y}\right) \tag{27.167}$$

and Peltier heat

$$h_{\text{Peltier}} = -\frac{k_B T}{e}\left[\frac{d\ln(n)}{dy} j_{n,y} - \frac{d\ln(p)}{dy} j_{p,y}\right] \tag{27.168}$$

in Boltzmann approximations are shown in Figure 27.13d. The Thompson heat is negative due to the temperature gradient. The Peltier heat is positive or negative corresponding to the signs of the gradients of the carrier densities. Except in the p-cladding layer ($y > 3$ μm) it dominates over the Peltier heat. Note that the Peltier heat results in a cooling of the p-confinement layer. The integrated heat powers are $Q_{\text{Joule}} = 10.2$ W, $Q_{\text{abs}} = 2.7$ W, $Q_{\text{rec}} = 1.3$ W, and $Q_{\text{defect}} = 1.9$ W. Hence Joule heat amounts to more than 50% of the total heat.



(a) (b) (c) (d)

FIGURE 27.13 Vertical profiles of the heat sources of a high-power laser. (a) Absorption heat, (b) recombination heat, (c) Joule heat, and (d) Thomson–Peltier heat. Heteroboundaries are indicated by dotted vertical lines.

27.6.3 Energy Conservation

Inserting Equations 27.149 and 27.148 into the heat sources (Equations 27.155, 27.158 through 27.160) and integrating over the device volume V leads to

$$\begin{aligned}\int_V c_{\mathrm{h}}\partial_t T\, dV - \int_V \boldsymbol{\nabla}\kappa_{\mathrm{L}}\boldsymbol{\nabla}T\, dV = k_{\mathrm{B}}\int_V T(\partial_t n + \partial_t p)\,\mathrm{d}V \\ + \int_V \boldsymbol{j}_n\boldsymbol{\nabla}(TP_n - \varphi_n)\, dV - \int_V \boldsymbol{j}_p\boldsymbol{\nabla}(TP_p + \varphi_p)\,\mathrm{d}V + \int_V eR(TP_n - \varphi_n)\,\mathrm{d}V \\ + \int_V eR(TP_p + \varphi_p)\mathrm{d}V - \partial_t\int_V u_{\mathrm{rad}}\,\mathrm{d}V - \int_V \gamma_{\mathrm{rad}}\,\mathrm{d}V \end{aligned} \tag{27.169}$$

Using a Green's identity we can convert

$$\int_V \boldsymbol{j}_n\boldsymbol{\nabla}(\mathrm{TP}_n - \varphi_n)\,\mathrm{d}V = \int_{\partial V}(\mathrm{TP}_n - \varphi_n)\boldsymbol{j}_n\cdot\boldsymbol{n}dS - \int_V(\mathrm{TP}_n - \varphi_n)\underbrace{\boldsymbol{\nabla j}_n}_{e(R+\partial_t n)}\,\mathrm{d}V \tag{27.170}$$

and

$$-\int_V \boldsymbol{j}_p\boldsymbol{\nabla}(\mathrm{TP}_p + \varphi_p)\,\mathrm{d}V = -\int_{\partial V}(\mathrm{TP}_p + \varphi_p)\boldsymbol{j}_p\cdot\boldsymbol{n}\mathrm{d}S + \int_V(\mathrm{TP}_p + \varphi_p)\underbrace{\boldsymbol{\nabla j}_p}_{-e(R+\partial_t p)}\,\mathrm{d}V \tag{27.171}$$

where ∂V denotes the surface of the device with $\boldsymbol{n}$ being the normal vector. Hence the terms containing the recombination rate cancel, and after rearranging we obtain

$$\begin{aligned}&\int_V c_{\mathrm{h}}\partial_t T\,\mathrm{d}V - \int_{\partial V}\kappa_{\mathrm{L}}\boldsymbol{\nabla}T\cdot\boldsymbol{n}dS \\ &= \int_V \underbrace{(Tk_{\mathrm{B}} - e\mathrm{TP}_n + e\varphi_n)}_{-u_n+e\varphi}\partial_t n\,\mathrm{d}V + \int_V \underbrace{(Tk_{\mathrm{B}} - e\mathrm{T}P_p - e\varphi_p)}_{-u_p-e\varphi}\partial_t p\,\mathrm{d}V \\ &+ \int_{\partial V}(\mathrm{TP}_n - \varphi_n)\boldsymbol{j}_n\cdot\boldsymbol{n}\mathrm{d}S - \int_{\partial V}(\mathrm{T}P_p + \varphi_p)\boldsymbol{j}_p\cdot\boldsymbol{n}\mathrm{d}S \\ &- \partial_t\int_V u_{\mathrm{rad}}\,dV - \int_V \gamma_{\mathrm{rad}}\,\mathrm{d}V\end{aligned} \tag{27.172}$$

From the Poisson equation (Equation 27.141) we can derive the relation

$$e\int_V \varphi(\partial_t n - \partial_t p)\,\mathrm{d}V = \varepsilon_0\int_{\partial V}\varphi\varepsilon_{\mathrm{s}}\partial_t\boldsymbol{\nabla}\varphi\cdot\boldsymbol{n}\mathrm{d}S - \frac{\varepsilon_0}{2}\int_V \varepsilon_{\mathrm{s}}\partial_t|\boldsymbol{\nabla}\varphi|^2\,\mathrm{d}V \tag{27.173}$$

where we applied again a Green's identity. Using this relation and the expression for the heat capacity Equation 27.152 we obtain the energy balance equation

$$\frac{d\int_V u\,\mathrm{d}V}{\mathrm{d}t} = -\int_{\partial V}\boldsymbol{j}_u\cdot\boldsymbol{n}dS - \int_V \gamma_{\mathrm{rad}}\,\mathrm{d}V \tag{27.174}$$

where u is the total energy density (sum of electro-static, internal, and radiative energy)

$$u = \frac{\varepsilon_0\varepsilon_s}{2}|\nabla\varphi|^2 + c_L T + u_n n + u_p p + u_{\mathrm{rad}}, \tag{27.175}$$

and $\boldsymbol{j}_u$ is the energy current density,

$$\boldsymbol{j}_u = -\varepsilon_0\varepsilon_s\varphi\partial_t\nabla\varphi - \kappa_L\nabla T - (TP_n - \varphi_n)\boldsymbol{j}_n + (TP_p + \varphi_p)\boldsymbol{j}_p \tag{27.176}$$

both already introduced in [74]. The first term in Equation 27.176 is related to the displacement current density. The other terms can be reduced to the entropy current density multiplied by T and the particle flux multiplied by the respective quasi-Fermi potentials.

In what follows, we consider the steady state ($d/dt = \partial_t = 0$) and evaluate the surface integral in Equation 27.174. We assume no flow of electrical current through the surface, except at the n-contact located at $y = 0$ and the p-contact at $y = H$:

$$\left.\begin{aligned} \boldsymbol{j}_n \cdot \boldsymbol{n} = 0 \\ \boldsymbol{j}_p \cdot \boldsymbol{n} = 0 \end{aligned}\right\} \quad \text{for} \quad y \neq 0 \quad \text{and} \quad y \neq H \tag{27.177}$$

Between the contacts a forward bias U is applied, so that

$$\varphi_n|_{y=H} = \varphi_p|_{y=H} = U \qquad \text{and} \qquad \varphi_n|_{y=0} = \varphi_p|_{y=0} = 0 \tag{27.178}$$

hold. The normal components of the electron current density at the p-contact $y = H$ and the hole current density at the n-contact $y = 0$ are assumed to vanish,

$$j_{n,y}|_{y=H} = j_{p,y}|_{y=0} = 0 \tag{27.179}$$

Similarly, we assume no heat flow through the surface, except at the surface, located at $y = H$, attached to the heatsink where

$$\kappa_L\partial_y T|_{y=H} = \frac{T_{\mathrm{ref}} - T|_{y=H}}{r_{\mathrm{th}}} \tag{27.180}$$

with r_{th} being the thermal transmission resistance (unit Km^2/W). By inserting the boundary conditions into Equation 27.174 we get for the steady state

$$\iint \frac{T|_{y=H} - T_{\mathrm{ref}}}{r_{\mathrm{th}}}\,\mathrm{d}x\mathrm{d}z = UI - \int_V \gamma_{\mathrm{rad}}\,\mathrm{d}V + \iint [(TP_p)|_{y=H} - (TP_n)|_{y=0}]j\,\mathrm{d}x\mathrm{d}z \tag{27.181}$$

with $j = j_{n,y}|_{y=0} = -j_{p,y}|_{y=H}$ and $I = \iint j\,\mathrm{d}x\mathrm{d}z$. The lhs of Equation 27.181 is the heat flow to the heatsink. The first term on the rhs is the electric input power UI and the second term is the optical power that leaves the cavity. The last term can be considered as Peltier power, which is generated between the electric contacts in the presence of a current flow and results into heating or cooling. Assuming that the spontaneous emission is absorbed in the cavity so that $\gamma_{\mathrm{rad}} = \gamma_{\mathrm{st}}$, using Equation 27.161 and the boundary conditions Equations 27.88 and 27.87, the second term can be shown to be (cf. Equation 27.105)

$$\int_V \gamma_{\mathrm{rad}}\,dV = P_{\mathrm{out}} \tag{27.182}$$

Thus in the steady state the total heat generated in the cavity is given by the electrical input power *UI* minus the optical output power, which coincides with Equation 27.11, minus or plus the Peltier heat.

28.4 Summary 78

28.1 Introduction

The brightness of an optical source is commonly defined as the emitted power per unit of emitting area and per unit of the solid angle into which the power is emitted (Walpole 1996). Therefore, a high-brightness source requires not only a high value of the emitted power but also a high “beam quality” in terms of a low product of the beam size and the beam divergence. The product of the beam radius at waist and the beam divergence half angle is called “beam parameter product” and based on it, the most widely used figure of merit for beam quality, the beam propagation ratio M^2, is defined as the ratio of the beam parameter product of the beam of interest to the beam parameter product of a diffraction-limited, perfect Gaussian beam (TEM_{00}) of the same wavelength λ (ISO 2005; Siegman et al. 1998). Therefore, a value $M^2 = 1$ represents an ideal diffraction-limited source, while values higher than unity indicate a degradation of the beam quality.

Semiconductor lasers are optical sources with very well-known advantages over other types of optical sources: small size, high conversion efficiency, and low cost. There are many applications of semiconductor lasers demanding high brightness: material processing, optical pumping of solid state and fiber lasers, medical treatments, optical wireless communications, and in general all applications requiring high power launched into an optical fiber. However, the brightness of a semiconductor laser is usually limited due to two counteracting requirements: a large emitting area is required to produce high power with reduced bulk and surface heating, while reduced dimensions are required to maintain a single spatial mode and thus a high-quality beam. High-power semiconductor lasers are based on broad-area (BA) devices, with a poor beam quality along the lateral axis, while devices with reduced lateral dimensions and good beam quality, such as ridge waveguide (RW) lasers, suffer from a limited maximum output power.

As a consequence, an important research effort has been devoted to improve the brightness of semiconductor lasers during the last years and various new approaches have been proposed, including lasers with a tapered gain region (Walpole 1996; Wenzel et al. 2003; Sumpf et al. 2009), the master-oscillator power amplifier configuration (O'Brien et al. 1993; Spreemann et al. 2009), and the angled grating distributed feedback laser (Lang et al. 1998; Paschke et al. 2003). Tapered lasers, also called flared unstable cavity lasers, are possibly the best choice to achieve high brightness at moderate cost, due to the technological simplicity of their fabrication process.

The schematic of a typical tapered laser is shown in Figure 28.1a. It is similar to the tapered semiconductor optical amplifier (SOA) described in Chapter 22 of this book (Tijero et al. 2017). In brief, it is composed of a straight and narrow index-guided (IG) section, usually an RW structure, and a gain or IG tapered section where the beam is amplified. Ideally, the optical beam of a taper laser is a single lateral mode that diffracts at the exit of the RW section and is amplified in the tapered section while preserving its shape. The main difference with the tapered SOA is that the reflectivities of the facets are modified to provide laser oscillation at a reasonable value of the injection current. The output facet is usually antireflection (AR) coated while the back facet is coated to provide a high reflectance (HR) in order to decrease the threshold current and to maximize the output power. In many cases, the designs include beam spoiler elements in the form of trenches located in the neighborhood of the border between the RW and the tapered section (Figure 28.1a) (Kintzer et al. 1993). The main role of these elements is to filter the backward propagating field out of the RW. Most of the tapered lasers are based on a standard Fabry–Pérot cavity and therefore they present multiple longitudinal mode spectra. Some designs include a distributed Bragg reflector (DBR) at the end of the RW in order to provide narrow and stable emission spectra (Hasler et al. 2008).

In comparison with other semiconductor lasers, the specific design of tapered lasers leads to an optical beam with strong astigmatism. The virtual source for the vertical (y) axis (sometimes referred to as fast axis) is located at the output facet of the laser from where the beam diffracts in air. However, in the lateral (x) axis (sometimes referred to as slow axis), the beam diffracts from the exit of the RW section in the semiconductor medium and therefore, at low power, the separation between the two virtual sources (astigmatism) is approximately given by the taper section length L_{TAP} divided by the effective index n_{eff}. This is illustrated in Figure 28.1b. In the vertical axis, the beam can be considered as diffraction limited no matter the power. However, in the lateral axis the beam often degrades losing its diffraction-limited character when the power increases. As mentioned earlier, this degradation is usually characterized by the beam propagation ratio M^2. Referring to Figure 28.1c, the beam parameter product, bpp, and M^2 in the lateral axis are, respectively, given by

$$\text{bpp} = W_{0x}\theta_x \text{ and } M^2 = \frac{\pi}{\lambda}\text{bpp} \tag{28.1}$$

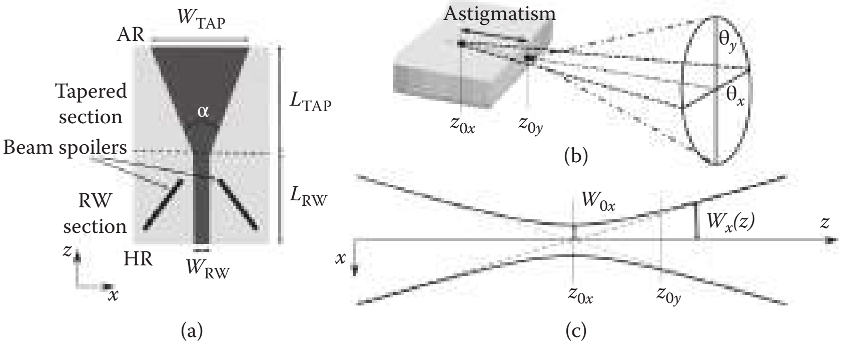

FIGURE 28.1 (a) Schematics of a gain-guided tapered laser. The shaded area is the contact region. Grooves acting as beam spoilers are also depicted. (b) Schematics showing the far field distribution of a tapered laser as a consequence of astigmatism. (c) Evolution of the beam size in the lateral direction along the propagation axis z.

(λ/π being the bpp of a Gaussian beam of wavelength λ). In Equation 28.1, W_{0x} is the beam half width at the virtual source position (beam waist half width), and θ_x is the beam divergence half angle (far-field half width) given by

$$\theta_x = \lim_{z\to\infty} \frac{W_x(z)}{(z - z_{0x})} \tag{28.2}$$

where $W_x(z)$ is the beam half width at the z position and z_{0x} the virtual source location. It is important to point out here that the beam sizes in Equations 28.1 and 28.2 (and therefore the beam divergence) are defined in terms of the second-order moment (variance) of the power density distribution by $W_x(z) = 2\sigma_x(z)$ where

$$\sigma_x^2(z) = \frac{\int\limits_{-\infty}^{\infty}\int\limits_{-\infty}^{\infty} P(x,y,z)(x-\bar{x})^2 \mathrm{d}x\,\mathrm{d}y}{\int\limits_{-\infty}^{\infty}\int\limits_{-\infty}^{\infty} P(x,y,z)\mathrm{d}x\,\mathrm{d}y} \tag{28.3}$$

and $\bar{x}$ is the first order moment of the power density distribution (x coordinate of the centroid) (ISO 2005). When $W_x(z)$ is defined in this way, and only in this case, the evolution of the beam lateral size along the propagation axis z for any simple astigmatic beam can be described by the hyperbola depicted in Figure 28.1c and given by

$$W_x(z) = W_{0x}\sqrt{1 + \left(\frac{M^2\lambda(z - z_{0x})}{\pi(W_{0x})^2}\right)^2} \tag{28.4}$$

The fitting of the measured $W_x(z)$ to this expression is a method for the experimental determination of M^2, W_{0x}, and z_{0x} (ISO 2005).

Nevertheless, it is a common practice in the research groups having developed tapered lasers in the last years to characterize the beam quality by the parameter $M^2(1/e^2)$ (Krakowski et al. 2002; Sumpf et al. 2002), using the expression

$$M^2(1/e^2) = \frac{\pi}{\lambda}\theta_x(1/e^2)W_{0x}(1/e^2) \tag{28.5}$$

where $\theta_x(1/e^2)$ and $W_{0x}(1/e^2)$ are the half widths of the divergence and virtual source at $1/e^2$, respectively. For Gaussian beams $M^2(1/e^2) = M^2 = 1$ and in general $M^2(1/e^2)$ is a useful parameter to compare different lasers and to estimate the efficiency of the source to couple power into a reduced area device, such as a single mode fiber. However, $M^2(1/e^2)$ for non-Gaussian beams is usually much lower than M^2 and it is not actually a beam propagation ratio in the sense that it is not an invariant of the beam when it propagates in air or across passive, nonaberrating optical elements as required by a real beam propagation ratio. Therefore, the reader should be aware of this when interpreting the real relevance of this parameter. An example of the severe discrepancies between M^2 and $M^2(1/e^2)$ for a non-Gaussian beam will be commented in Section 28.3.5.

Two clearly different types of tapered lasers have been reported to date: gain-guided (GG) and IG lasers. The GG tapered lasers feature a relatively large full taper angle, α_{tap}, electrically defined in the p-contact layer. In these lasers, α_{tap} is designed to match the free diffraction angle (typically 4°–8°, depending on wavelength), as we will describe later. In the IG tapered lasers a small taper angle ($\alpha_{\text{tap}} < 1°$) is defined both, electrically in the p-contact layer and optically by an effective index step created by removing a fraction of the upper epitaxial layers. The beam properties of the two kind of tapered lasers are significantly different (Borruel et al. 2004a). GG tapered lasers with a taper angle close to the free diffraction angle have been fabricated at many different wavelengths from red (Blume et al. 2012) to around 2μm (Pfahler et al. 2006). A review of previous work on these devices can be found in Wenzel et al. (2003) and Sumpf et al. (2009). GG tapered lasers have demonstrated good beam quality and continuous wave (cw) output powers higher than 10 W at 980 nm (Fiebig et al. 2009), 1060 nm (Sumpf et al. 2009), and 1030 nm (Müller et al. 2016). Narrow IG tapered lasers have achieved more than 1 W at 980 nm (Krakowski et al. 2003) and 915 nm (Michel et al. 2005). Narrow IG lasers are usually combined in parallel arrays in high-power laser bars (Auzanneau et al. 2003; Wilson et al. 1999).

It is well known that the interaction between the optical field and the semiconductor gain media promotes a complex spatial-spectral dynamics in semiconductor lasers. In the case of tapered lasers, nonlinear effects, such as spatial hole burning (SHB) and thermal lensing add complexity to the physical phenomena involved and make the high power behavior to significantly deviate from the ideal low-power performance. Efficient and accurate modeling approaches are thus necessary to analyze and predict the beam properties of tapered lasers in order to design new geometries with improved performance. During last 20 years, different approaches have been applied to the modeling and simulation of tapered lasers and amplifiers. For a review see (Tijero et al. 2017) in this book.

Our group at the Universidad Politécnica of Madrid, in collaboration with the University of Nottingham, developed CONAN (Borruel et al. 2002, 2004a; Sujecki et al. 2003), a sophisticated simulator for tapered lasers that solves the electrical, optical, and thermal equations for these devices. Despite the assumptions needed to reduce the model complexity (steady state, single frequency, two-dimensional [2D] propagation of the optical mode), the simulations showed good qualitative and quantitative agreement with experimental results in tapered lasers with different geometries and based on different materials (Sujecki et al. 2003; Borruel et al. 2004a; Odriozola et al. 2009; Esquivias et al. 2010). Furthermore, the simulator demonstrated to be a useful tool to predict the behavior of novel designs prior to their fabrication (Borruel et al. 2005; Michel et al. 2009). Other models in literature (Williams et al. 1999; Mariojouls et al. 2000), based on similar approaches, have also reproduced the main trends observed experimentally.

In this chapter, we present a didactic overview of how the main beam characteristics of high-brightness tapered lasers can be accounted by simulation approaches with specific detail devoted to our simulation tool, and provide illustrative examples representative of some of the most typical behaviors of these devices. After this introduction, Section 28.2 presents a brief description of our simulation model and our procedure to calibrate the model in comparison with experimental results; in Section 28.3, we apply the model to three devices representative of some of the most common geometries and guiding mechanisms and analyze how geometry and guiding determine the beam characteristics. The chapter ends with a summary in Section 28.4.

28.2 Simulation Model

28.2.1 Model Overview

Our quasi-3D (three-dimensional) model (Borruel et al. 2002, 2004a; Sujecki et al. 2003) solves self-consistently the complete steady-state electrical, thermal, and optical equations for the tapered laser, assuming single-frequency operation. The laser simulator includes a 3D electrical solver of the Poisson and continuity equations coupled to a 3D thermal solver of the heat-flow equation with the local heat sources provided by the electrical solution. The optical fields in the tapered laser are solved using a 2D wide-angle finite-difference beam propagation method (WA-FDBPM) making use of the effective index approximation (Hadley 1992). Further details of the model can be found in Chapter 22 of this book, which is devoted to tapered SOAs (Tijero et al. 2017). Here, we briefly describe the model for completeness, in order to emphasize the differences when applying it to tapered lasers instead of tapered amplifiers. In fact, the main difference is that in the simulator for tapered amplifiers the WA-FDBPM is applied for the propagation of the optical solution only in the forward direction, while in the case of tapered lasers, the optical solution has to be propagated in both, the forward and then in the backward direction taking into account the corresponding reflectivities of the front and rear facets as corresponds to an optical resonator (Fox and Li 1961). Table 28.1 summarizes the main physical effects included in the model and how their dependence on temperature, wavelength, or carrier densities has been considered.

The simulator flow is shown in Figure 28.2. The solution procedure is initialized by a one-dimensional (1D) laser simulator (Harold, 3.0) which provides for each bias current the lasing wavelength, the bias voltage, and the average photon density in the laser cavity. The tapered laser is divided into 2D slices perpendicular to the z-axis at positions z_i where $i = 1, \dots, N$. The 1D average photon density is used to define an initial guess optical field at the first slice, at the rear facet of the device. The photon density of this field is used as input for the electrothermal solver to calculate the lateral gain and refractive index perturbation profiles in the first slice. With these inputs, a 2D WA-FDBPM making use of the effective index approximation propagates the optical field through the first slice and provides the electrothermal solver with the photon density profile corresponding to the next slice. This procedure is repeated until arriving to the front facet of the device, $i = N$. After applying the electrothermal solver to the last slice, the output power P_{out} and the excess power P_{exc} are calculated (Tijero et al. 2017) and used as inputs for a 3D thermal solver that is applied to the entire cavity and provides a new temperature profile. The whole process is repeated backward, i.e., propagating the solution from the front to the rear facet. After a number of round trips or iterations, the steady state for all the electrical, thermal, and optical variables is found.

TABLE 28.1 Main Physical Effects Included in the Model

Physical Effect or Parameter	Included	Comments
Temperature dependence of energy gap	YES	Empirical Varshni form
Band-gap renormalization	NOT	
Contribution to current density from thermal gradients	YES	Defined by the electron and hole thermoelectric powers
Carrier capture/escape processes in the quantum well (QW)	YES	Defined by electron and hole capture times
Thermionic emission in heterojunctions	NOT	
Fermi–Dirac statistics in bulk materials	NOT	
Dependence of electron and hole mobilities on dopant concentration	YES	Electric field and temperature dependencies not included
Auger recombination	YES	Temperature-dependent Auger parameters
Shockley–Read–Hall (SRH) nonradiative recombination	YES	Complete SRH formula, dependent on both electron and hole carrier concentrations, and on trap properties (density, energy, and degeneration factor of the trap, considering a temperature-dependent capture cross section)
Wavelength dependence of refractive index	YES	Temperature dependence not included
Free-carrier absorption	YES	Linear with local carrier concentration, defined by electron and hole free-carrier absorption coefficients
Nonconstant linewidth enhancement factor	YES	Calculated in QW region from a carrier-dependent differential refractive index, and carrier and wavelength-dependent differential gain
Gain broadening	YES	Lorentzian function
Coulomb enhancement of the gain	NOT	
Spontaneous emission noise	NOT	
Detailed calculation of local heat sources	YES	Local heat sources: Joule effect, nonradiative recombination, free-carrier absorption
Temperature dependence of thermal conductivities	YES	Included in semiconductor layers

FIGURE 28.2 Main flow of the quasi-3D simulator for tapered lasers CONAN.

The convergence criterion is based on the stability of the optical field at the rear facet after consecutive iterations, both in shape and power. It can be expressed in terms of a parameter ε as

$$\varepsilon = \frac{\left\langle \left|E_n(x) - E_{n-1}(x)\right|, \left|E_n(x) - E_{n-1}(x)\right| \right\rangle}{\left\langle \left|E_n(x) + E_{n-1}(x)\right|, \left|E_n(x) + E_{n-1}(x)\right| \right\rangle} \tag{28.6}$$

where $E_n(x)$ is the optical field at the rear facet after n iterations and $\langle , \rangle$ denotes the scalar product. The iterative process finishes when ε is lower than a threshold value supplied by the user, typically 5×10^{-5}.

As commented previously, in order to filter the front facet back-reflected optical field reaching the ridge section, some tapered devices include beam spoilers (Walpole 1996). The beam spoilers are modeled by setting the optical field to zero at the beam spoiler locations (Mariojouls et al. 2000).

It should be noticed that our algorithm uses a fixed lasing wavelength provided by the 1D simulator. In a more rigorous approach, the lasing wavelength should be recalculated during the quasi-3D algorithm in order to take into account the spatial effects on it. Nevertheless, the comparison with experimental results has proven the approximate validity of our approach.

In some cases, the tapered lasers are fabricated with separate contacts for each section (Paschke et al. 2005; Odriozola et al. 2009; Michel et al. 2009). The model takes into account this possibility and allows the different sections to have different bias voltages. This is implemented as follows: after the initialization, the 1D simulator provides the laser wavelength, the initial photon density, and a bias voltage V_0. Then, for each section *i*, the applied bias voltage is recalculated as $V_i = V_0 + \Delta V_i$, where ΔV_i can be positive or negative. With these voltage inputs, the simulator proceeds normally and finally, the current at each section is calculated by integration of the current density.

The model can also be applied to the simulation of tapered lasers under patterned injection current (Borruel et al. 2004b). This is an interesting strategy aimed at counteracting the detrimental effects of the SHB. For this, a predefined function that laterally scales the epilayer material conductivities is introduced in the simulator. In this way, the local resistance is modified and therefore the current density profile is also modified according to the conductivity profile.

28.2.2 Model Options Regarding Symmetry

Our simulation procedure is based on launching a trial optical field and solving the forward and backward propagation until convergence (Fox and Li 1961). Depending on the symmetry of the initial trial optical field, the model has three versions:

- Half-cavity (HC) model: This is the basic version of the model. In this version, as in similar models (Williams et al. 1999; Mariojouls et al. 2000), the trial optical field is the fundamental mode of the passive RW section (an even function), although we have checked that the final optical field is independent of the shape of the initial field, provided it is an even function. Since the beam propagation method (BPM) preserves the parity of the field and the device is symmetric, only half of the cavity needs to be explicitly solved, thus reducing the computational effort. However, this version cannot take into consideration the effect of the odd components of the field and fails in reproducing some experimental features of the beam properties of IG tapered lasers, such as the excitation of secondary lateral modes. Therefore, the model was upgraded and two versions including optical fields with both odd and even components were created (Esquivias et al. 2010).
- Full cavity coherent coupling (FCCC) model: In this version, the equations are solved in the full cavity and the initial trial field is an asymmetric field $E_{\mathrm{a}}(x)$, containing odd and even components, i.e., $E_{\mathrm{a}}(x) = E_{\mathrm{e}}(x) + E_{\mathrm{o}}(x)$. The photon density is taken as proportional to $|E_{\mathrm{a}}(x)|^2$ with $E_{\mathrm{a}}(x)$ being the optical field after the propagation by the BPM through the previous slice. This photon density is in general asymmetric, although it can result in a final symmetric solution, depending on the particular device under study. This version often produces a snake-like intensity profile in the plane of the active layer. The corresponding near-field (NF) and far-field (FF) profiles are asymmetric and the intensity profile is not stable after subsequent roundtrips. This kind of behavior has been experimentally observed and attributed to the coherent coupling of frequency-locked lateral modes (Guthre et al. 1994).
- Full cavity incoherent coupling (FCIC) model: As in the FCCC version, the equations are solved in the full cavity and the initial trial field is an asymmetric field $E_{\mathrm{a}}(x)$, but in this case, the photon density is calculated as proportional to $|E_{\mathrm{s}}(x)|^2$, the addition of the field intensities of the even and odd components of $E_{\mathrm{a}}(x)$: $|E_{\mathrm{s}}(x)|^2 = |E_{\mathrm{e}}(x)|^2 + |E_{\mathrm{o}}(x)|^2$. In this way, the photon density is symmetric, and consequently also the carrier and temperature profiles. This approach is equivalent to the simultaneous propagation of an even and an odd field with slightly different frequencies and therefore only coupled through its interaction with the gain medium, i.e., incoherently coupled. This version is more appropriate than the HC model for IG lasers supporting higher order lateral modes besides the fundamental mode.

28.2.3 Model Calibration and Comparison with Experiments

A critical point in all sophisticated laser models is the high number of relatively unknown material parameters. Some of them (energy band parameters, refractive index, etc.) are specific of the different semiconductor materials used in the device. These are usually well known only for the most common binary materials (GaAs, InP), relatively well known for some ternary alloys and relatively unknown for many other alloys. Even for the best known materials, the temperature or wavelength dependence of some parameters has not been reported. In addition, other important parameters (scattering losses, trap characteristics, etc.) depend on the particular fabrication process, and can be different for nominally identical materials. As a consequence, it is always necessary to calibrate the model parameters with experimental results in order to reproduce the experiments and to predict the trends of the device performance when modifying the material composition or the device geometry.

The main idea is to find, if possible, a set of simulation parameters such that the model reproduces the main trends of relevant experimental results, such as power–voltage–current characteristics, FF and NF patterns, and evolution of M^2 and FF and NF patterns with current. If these simulation parameters conveniently account for the main physical effects causing the observed beam properties, then the model will predict qualitatively, and even quantitatively, the performance of new devices based on the same materials but with different design. In other words, it is not so important to use a complete set of correct material parameters, but rather to find out those parameters relevant for the model and related to the main internal process limiting the maximum power or degrading the beam quality.

Our calibration process includes three steps, the first one at theoretical level, the second one by comparing with experimental results in BA lasers, and the third one by comparing with results in tapered lasers. Prior to the calibration, it is important to consider the entire epilayer structure and find out in the literature as many material parameters as possible, especially in the most standard references (Adachi 1992; Vurgaftman et al. 2001). Unfortunately, as stated above, many important parameters, such as refractive index, Auger, and free-carrier absorption coefficients, have never been measured for new materials or alloy compositions, in which case we use judicious guess values based on the parameter values in other alloys with similar gap or composition.

The first step of the calibration procedure is the fitting of the parameters used to calculate the material gain spectra $g_{\text{mat}}(\lambda)$ and the spontaneous recombination rate R_{sp}, as a function of the electron and hole quasi-Fermi energies. As it is described in Tijero et al. (2017), the simulation tool operates with a parabolic band model for the calculation of these functions but takes into account band mixing effects by the following fitting procedure: first, we use a valence band (VB) mixing model (Coldren and Corzine 1995), to calculate the quantum well (QW) energy levels and the maximum gain and the spontaneous recombination rate versus carrier concentration, $g_{\max}(n)$, and $R_{\text{sp}}(n)$. Then, these calculations are fitted by the results provided by the simulation tool using same formulation but considering parabolic valence subbands. The fitting parameters are the QW energy levels, the effective mass of each level, and two scaling parameters (multiplying factors) for $g_{\text{mat}}(\lambda)$ and for R_{sp}. Finally, the tool is fed with the parameters that best fit $g_{\max}(n)$ and $R_{\text{sp}}(n)$ obtained by the VB mixing model. Very good agreement was achieved for a wide range of carrier densities.

The second step in the calibration procedure is to compare 1D simulations with experimental results in BA lasers fabricated with the same epitaxial material than the tapered lasers. It is important to include power–current (P–I) characteristics for lasers with different cavity lengths measured at different temperatures, as well as the FF patterns along the vertical axis. The goal of this step is to determine those simulation parameters related to the material quality (scattering losses and Shockley–Reed–Hall recombination parameters), and also to modify those relevant parameters, which are not well known, such as the Auger coefficient and its temperature dependence. The comparison is made between measured and simulated results in terms of the threshold current density (J_{th}) dependence on the cavity length L, internal quantum efficiency, internal losses, and characteristic temperature T_0. The comparison between measured and calculated FF patterns provides a method to modify the refractive indices, especially that of the QW, which is very important for the calculation of the optical confinement factor in the simulations. The comparison between experimental and simulated current–voltage characteristics provides information on the total resistance of the device, which is relevant for a correct estimation of the Joule heating in the simulations.

The final stage of our calibration procedure includes two parameters: one to account for the carrier-induced refractive index change, and the other one to account for the heat transfer efficiency. For the first one, we focus on its effect on the beam divergence and fit the experimental value of the beam divergence at a fixed output power to the simulated value. This can be achieved by using as fitting parameter the coefficient n_1 that relates the index change and the carrier density assuming a square root dependence (Borruel et al. 2004a). Regarding heat transfer, in order to avoid extending the thermal simulation region, we artificially consider a heat-sink area equal to the device area and use the heat-sink thickness as fitting parameter. We use it to fit the experimental average temperature increase when increasing the current to the simulated temperature increase (on average). The experimental average temperature increase is estimated from the shift of the lasing wavelength when increasing the current, assuming a standard dependence. We have checked that by changing the heat sink thickness, the average value of the temperature changes without important modifications in the lateral and longitudinal temperature profiles.

This procedure was applied to 975 nm (IG and GG with beam-spoilers) and to 735 nm (GG without beam spoilers) tapered lasers in Borruel et al. (2004a). We found a good agreement in the P–I characteristics, shape of the NF and FF patterns, and especially in the evolution of beam properties (M^2, astigmatism, widths of NF at waist and FF patterns) with the injection level. Furthermore, we also found a good agreement between the maximum measured power in the 975 nm GG devices and the maximum power with numerical convergence in the simulations, indicating that the physical mechanism limiting the power was correctly reproduced. This good agreement provided the basis for a new geometrical design, the clarinet laser (Borruel et al. 2005), which showed beam properties similar to those predicted by the simulations. Our model was also applied to simulate the 915-nm IG lasers described in Michel et al. (2005), but in this case the experiments showed a double peak in the NF and FF which was not reproduced by the simulations and gave rise to the upgraded FCIC version of the model previously described. Additional comparisons between experiments and simulations can be found in Odriozola et al. (2009), Michel et al. (2009), and Esquivias et al. (2010).

28.3 Simulation Examples

In order to illustrate the capabilities of the simulation tools for accounting for the behavior of typical tapered laser geometries and guiding mechanisms, we have selected three representative geometries and guiding mechanisms sharing the same epitaxial structure. In this section, we analyze with our simulation tool CONAN the effect of these design parameters on the device performance. We devote specific attention to the comparative analysis of the effects on the beam properties of the device geometry and injection conditions. Since this analysis is presented here mainly for illustrative purposes, some interesting effects will be just overviewed without a detailed study. The half-cavity version of the simulator was used in the three examples. The simulations were performed under isothermal conditions to concentrate the focus in carrier-related effects, since thermal effects are strongly dependent on the value of some relatively unknown material parameters. A detailed discussion on the role of thermal effects in tapered lasers can be found in Esquivias et al. (2010).

28.3.1 Device Geometries and Simulation Parameters

The epitaxial structure of the simulated devices corresponds to that of the 1060 nm GG tapered lasers reported in Ruiz et al. (2009). In brief, it consists of a strained InGaAs QW embedded in a large InGaAsP symmetric optical cavity with AlGaAs cladding regions. We will compare the beam properties of three devices: (1) a GG tapered laser with beam spoilers (GG-BS), (2) a GG tapered laser without beam spoilers (GG-NBS), and (3) a narrow IG laser without beam spoilers (IG).

The geometrical and material parameters used in the simulations are identical for the three devices except for the taper angle and guiding mechanism in the tapered section. The total cavity length is 3 mm and the taper angles are 6° and 1° for the GG and IG devices, respectively. Table 28.2 shows these parameters as well as a brief summary of the most influential material and device parameters used in the

TABLE 28.2 Geometrical Parameters of the Tapered Lasers and Summary of the Most Relevant Material and Device Parameters Used in the Simulation

Symbol	Parameter	Value	Units
L_{RW}	Length of the RW section	1	mm
W_{RW}	Width of the RW section	2.5	μm
L_{TAP}	Length of the taper section	2	mm
R_f	Front facet reflectivity	0.025	
R_b	Back facet reflectivity	0.95	
	Full aperture of beam spoilers	17	μm
	Distance from beam spoilers to back facet	1	mm
α_{tap}	Full taper angle	6 (GG); 1 (IG)	°
Δn_{eff}	Effective index step of the RW section	4.7×10^{-3}	
T_{HS}	Heat sink temperature	20	°C
Γ	Confinement factor	0.0084	
α_{scat}	Scattering losses coefficient	0.5	cm^{-1}
$C_n(C_p)$	Electron (hole) Auger recombination coefficient	$2(2) \times 10^{-30}$	cm^6s^{-1}
k_e, (k_h)	Electron (hole) free-carrier absorption coefficient	$3(7) \times 10^{-18}$	cm^2
n_I	Differential refractive index coefficient	4.5×10^{-11}	$cm^{3/2}$

simulation. These parameters were extracted from standard references or fitted after applying the calibration procedure described in Section 2.3 to the GG-BS device (Esquivias et al. 2010). The taper angle of the GG devices was selected so as to fit the calculated free diffraction angle assuming an index step $\Delta n_{eff} = 4.7 \times 10^{-3}$.

28.3.2 GG Tapered Laser with Beam Spoilers

The GG-BS device presented here is representative of GG tapered lasers with beam spoilers. At low power, these devices show single-lobed NF and FF patterns and low values of M^2. Figure 28.3a and b illustrates the evolution of the profile of the forward and backward optical field intensities along the cavity at low power (slightly above threshold). A more detailed view of the beam profiles at different longitudinal positions is provided in Figure 28.4a and b. The shape of the fundamental lateral mode of the RW section entering the gain section (see curve A in Figure 28.4a) can be approximated by a Gaussian function. In this example, the calculated full width of the mode at $1/e^2$ (W_{mode}) is 4 μm.

When entering the tapered section, the mode is subjected to two different effects: (1) amplification by the gain medium and (2) free diffraction if the full taper angle is larger than the free diffraction full angle θ_D (at $1/e^2$). The free diffraction angle of an ideal Gaussian beam is given by

$$tg\left({}^{\theta_D}\!/\!_2\right) = \frac{2 \cdot \lambda}{\pi \cdot n_{eff} \cdot w_{mode}} \tag{28.7}$$

where n_{eff} is the effective index of the vertical waveguide. In the case of the GG-BS device under analysis, the full taper angle (6°) has been chosen to match the value of θ_D. Figure 28.4a shows the lateral intensity profile of the forward traveling light at cross sections taken at several positions along the cavity (curve A at $z = 1$ mm, curve B at $z = 2$ mm, and curve C at $z = 3$ mm, $z = 0$ and $z = 3$ mm being the back and the output facet, respectively). The beam expands smoothly as it propagates along the tapered section and reaches the output facet keeping its Gaussian-like profile (curve C), although the wave front has a convex shape, and therefore the phase at the facet is far from being uniform. The reflected (or backward) field continues diffracting in its way back but now the freely diffracting beam does not overlap any more with the gain region and therefore the beam becomes narrower as it propagates backward. This evolution is

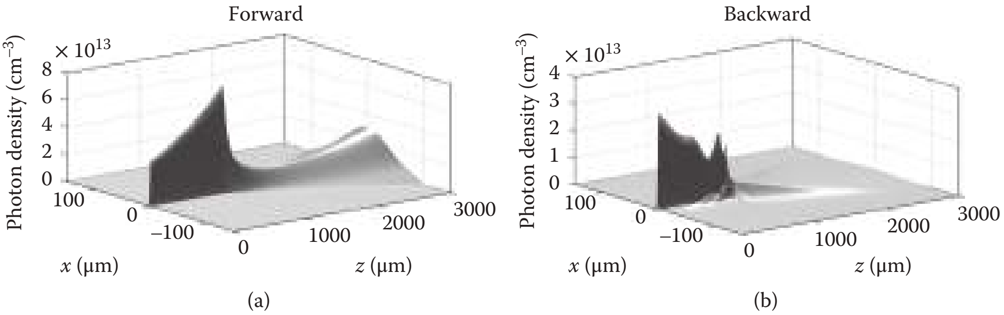

FIGURE 28.3 (a) Forward and (b) backward optical field intensity inside the cavity for the GG-BS tapered laser, when operated at low power ($P_{\text{out}} = 38$ mW).

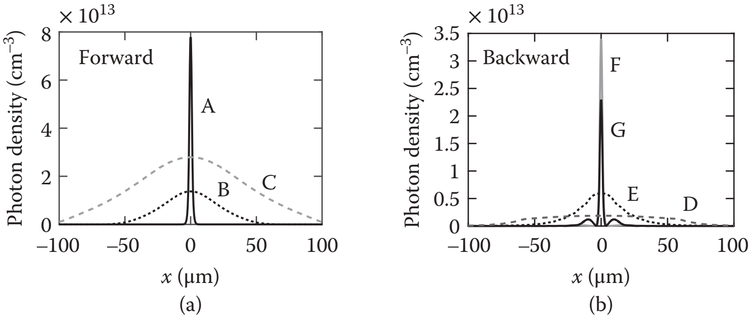

FIGURE 28.4 (a) Forward and (b) backward optical field intensities at different positions inside the cavity for the GG-BS device, when operated at low power ($P_{\text{out}} = 38$ mW). In panel (a): A at $z = 1$ mm, B at $z = 2$ mm, and C at $z = 3$ mm (output facet). In panel (b): D at $z = 2$ mm, E at $z = 1$ mm, F at $z = 0.5$ mm, and G at $z = 0$ mm (back facet).

illustrated in Figure 28.4b, where curves D and E show the intensity profiles at an intermediate position in the tapered region ($z = 2$ mm) and at the entrance of the RW section, respectively. As the beam entering the RW section is wider than the fundamental mode of this section (70 versus 4 μm at $1/e^2$), a substantial part of the power is not coupled producing the so-called coupling losses (Walpole 1996) or taper losses. The beam propagating along the RW section is filtered by the single-mode waveguide, with the help of the beam spoilers. Curves F and G are the profiles at the middle of the RW section and at the back facet of the device, respectively. The side lobes of curve F reveal that the filtering effect is still imperfect at the middle of the RW section (see also Figure 28.5b). However, at the back facet, the lobes have virtually disappeared and the beam is as narrow as the fundamental mode of the waveguide revealing that in this case the filtering effect is fully accomplished at the back facet. In other cases, the filtering could be still accomplished in the subsequent forward propagation along the RW and the second pass through the beam spoilers after the reflection at the back facet.

Even more insight into the evolution of the beam inside the cavity can be gained by the gray-scale plots in Figure 28.5. In these plots, the forward (Figure 28.5a) and backward (Figure 28.5b) photon densities in each slice perpendicular to the longitudinal axis have been normalized to their maximum value in the slice and white lines have been drawn at the border of the injected region and at the position of the beam spoilers. In comparison with the smooth and homogeneous expansion of the photon density profile of the forward field in the tapered section, the width of the backward field photon density profile increases from $z = 3$ mm to about $z = 2.5$ mm and decreases afterward due to the gain guiding in the narrower part of the tapered region. Nevertheless, at the entrance of the RW section, the photon density profile of the

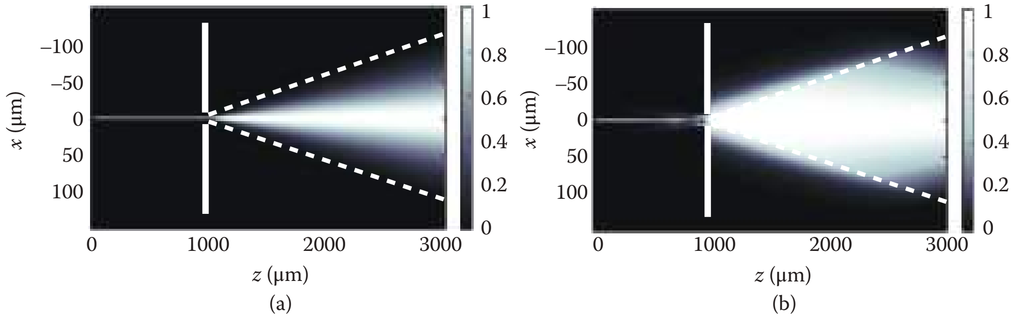

FIGURE 28.5 Normalized (a) forward and (b) backward optical field intensity inside the cavity at each z slice for the GG-BS device, when operated at low power (P_{out} = 38 mW). The white dashed lines indicate the pumped tapered region, while the white solid lines indicate the position of the beam spoilers.

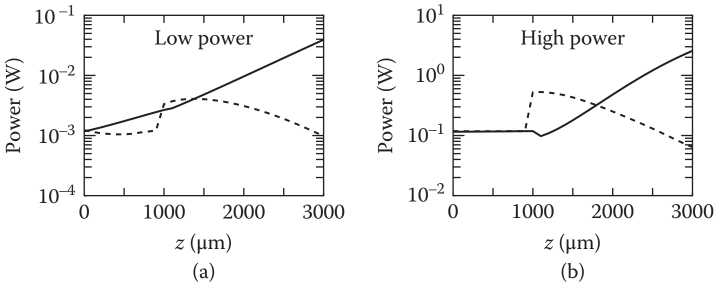

FIGURE 28.6 Optical power of the forward (solid) and backward (dashed) traveling optical fields along the cavity for the GG-BS laser, when operated at (a) low power (P_{out} = 38 mW) and (b) high power (P_{out} = 2.5 W).

backward field still expands far beyond the limits of the injected area. At this point, the filtering role of the beam spoilers is crucial and only tiny diffraction lobes survive after entering the RW section.

To complete the picture, the evolution along the cavity of the total powers carried by the forward and backward beams is shown in Figure 28.6. These powers were obtained by integration of the forward and backward photon densities in the lateral direction at each longitudinal position. In the logarithmic scale of Figure 28.6, an exponential growth of the power is represented by a straight line in which slope is proportional to the effective modal gain, defined as the difference between the modal gain and all the losses occurring in the beam propagation. At low power (Figure 28.6a), the forward field effective gain is constant in both sections. In this case, it is slightly lower in the RW section due to a lower material gain and a slightly worse overlapping with the optical mode in the RW section (not shown). The backward beam power shows initially an exponential growth up to about z = 2.5 mm due to the good overlapping with the gain region. The progressively worse overlapping makes the beam amplification to decreases down to negative values at the entrance of the RW section. At this point, the power drops down due to the filtering effect of the beam spoilers. The subsequent evolution of the backward propagating power is the result of the competing mechanisms of filtering and gain in the RW section, the balance being slightly positive at the back facet. The evolution of the forward and backward propagating powers at high power is illustrated in Figure 28.6b and is mentioned later in this section.

The nearly ideal behavior of the GG-BS device observed at low power changes dramatically when increasing the output power. The main reason for this is the mutual interaction in the semiconductor material between photons and carriers in a feedback loop leading eventually to power saturation and self-focusing at high output powers. Let us start with the optical mode profile. At high injection the mode narrows, thus concentrating a high photon density in the cavity axis. This high photon density depletes the carrier density along the cavity axis due to the higher stimulated recombination in this region, the so-called SHB effect. Figure 28.7a shows the simulated carrier density for the GG-BS device at the output facet for increasing output powers. The initially flat profile of the carrier density evolves when the injection increases to a "batman-ears" like profile, with maxima at the sides and minimum at the center. This profile has been experimentally observed through spontaneous emission measurements (Pagano et al. 2011). The carrier density minimum is limited by the transparency carrier density, 1.2×10^{18} cm^{-3} in our example. The initial simplified approach by Walpole (1996) suggested that the local gain saturation in the cavity axis caused by the SHB would induce an increase of the photon density in the side regions, leading to a top hat shape. But in semiconductor materials, a change of the carrier density produces simultaneously changes in the gain and in the refractive index, which are related by the linewidth enhancement factor. Figure 28.7b and c shows the corresponding gain and index profiles at the power levels of Figure 28.7a. The gain decreases at the cavity axis and the refractive index increases. The shape of the index profile produces a parasitic waveguide for the beam, with more important consequences on the beam shape than the gain profile. The carrier-induced waveguide produces a convergent lens effect during the beam propagation along the tapered region, which concentrates the power density at the center of the beam, thus closing the feedback loop (see Figure 28.4d).

At high power density, the strong feedback induces self-focusing of the beam, leading to saturation of the output power. This effect can be visualized with the help of Figure 28.8, where (as in Figure 28.5) we have plotted the forward (Figure 28.8a) and backward (Figure 28.8b) normalized photon densities at a high power level. In comparison with Figure 28.5a, the forward beam is much narrower, showing clearly the self-focusing. More difficult is the interpretation of the backward beam shape in the tapered section (Figure 28.8b). The expansion of the backward beam beyond the limits of the injected region adds to the gain guiding and the induced index guiding a new degree of complexity making the beam shape extremely difficult to interpret in simple terms. Again, the filtering role of the beam spoilers is apparent in the RW

FIGURE 28.7 (a) Carrier density, (b) material gain, (c) refractive index perturbation, and (d) photon density profiles at the output facet for the GG-BS laser at different output powers: $P_{\text{out}} = 38$ mW (solid), $P_{\text{out}} = 955$ mW (dashed), and $P_{\text{out}} = 2.5$ W (dotted). Vertical dashed gray lines indicate the pumped region limits.

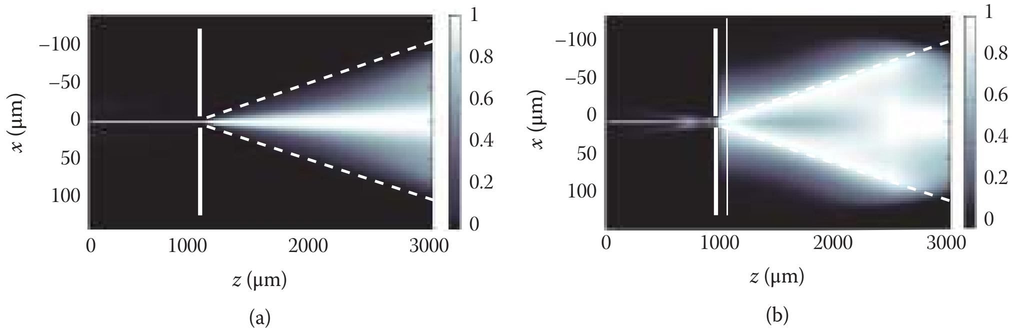

FIGURE 28.8 Normalized (a) forward and (b) backward optical field intensity inside the cavity at each z slice for the GG-BS device, when operated at high power ($P_{\text{out}} = 2.5$ W). The white dashed lines indicate the pumped tapered region, while the white solid lines indicate the position of the beam spoilers.

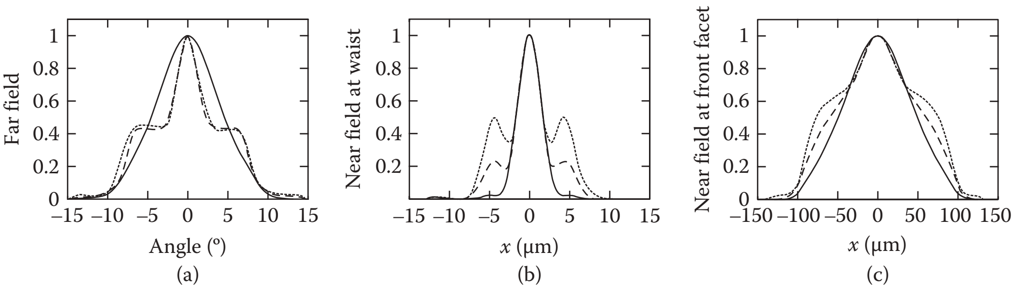

FIGURE 28.9 (a) Far field, (b) near field at waist, and (c) near field at the front facet for the GG-BS device at three power levels, $P_{\text{out}} = 38$ mW (solid), $P_{\text{out}} = 955$ mW (dashed), and $P_{\text{out}} = 2.5$ W (dotted).

section. The small diffraction lobes surviving at low power are now more noticeable and can even reach the back facet from where they are reflected as can be (hardly) seen in Figure 28.8a.

The evolution of the integrated forward propagating power at high injection (Figure 28.6b) shows also clear differences with respect to the low injection behavior. The nearly homogeneous effective gain for the forward field at low power (Figure 28.6a) becomes clearly different in the RW and tapered sections at high power. In the RW section, the effective gain vanishes revealing a strong gain saturation confirmed by a carrier density in this section slightly higher than the transparency value (not shown). As the total round-trip gain should be constant, the absence of gain in the RW section is compensated with the high values of the effective gain at the beginning of the tapered section. Further in the tapered section, the forward effective gain decreases slowly due once more to gain saturation. In contrast, the evolution of the backward propagating power at high injection is not significantly different from the low-injection behavior. In the RW section, after the sudden drop of the power due to the beam spoilers, the modal gain remains constant at a value close to zero as for the forward beam.

The SHB and self-focusing of the beam at high injection not only limit the maximum power, but also degrade the beam quality. Figure 28.9 shows the FF pattern and the NF patterns at waist and at the facet, at three power levels. Under simplifying ideal assumptions, the expected value of the FF width can be estimated by applying Snell's law to the beam at the output facet. In this case, this yields a full beam divergence angle θ_{out} (at $1/e^2$) $\sim n_{\text{eff}} \cdot \theta_{\text{D}} = 20°$ ($n_{\text{eff}} = 3.34$). The simulated value at low power is $\theta_{\text{out}} = 16.5°$, not far from the previous estimation. It is clear how the shape of the beam is modified by the carrier-induced convergent lens when increasing the power: the NF patterns at waist and at the front facet develop shoulders and the FF patterns evolve into a narrower central lobe together with the apparition of side lobes. These effects produce also an increase of the astigmatism and the value of M^2 is shown in Section 3.5.

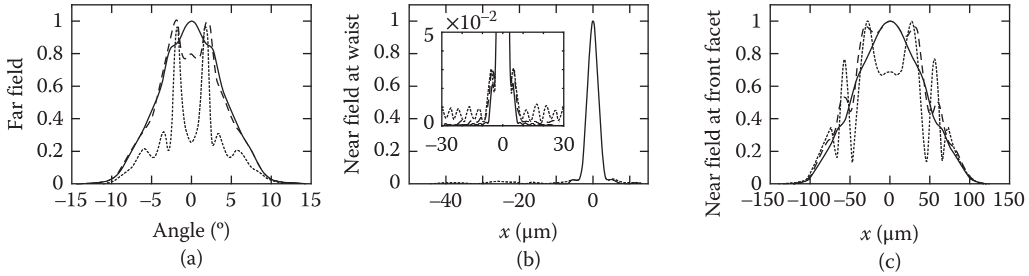
28.3.3 GG Tapered Laser without Beam Spoilers

The GG-NBS device presented here is representative of GG tapered lasers without beam spoilers. In spite of the advantages of the use of beam spoilers, they have also drawbacks due to the additional processing steps and also to the possible introduction of defects close to the active region. In fact, very high power levels have been reported for tapered lasers without beam spoilers (Sumpf et al. 2009; Müller et al. 2016). In this case, the filtering properties of the RW section had been improved by increasing its length, after a careful balance to optimize this design parameter (Wenzel et al. 2003). The main characteristic of the beam experimentally observed in tapered lasers without beam spoilers is a multilobed FF pattern, with an increasing number of lobes together with an increase of the peak to valley ratio when increasing the output power (Borruel et al. 2004a; Fiebig et al. 2009; Sumpf et al. 2009; Müller et al. 2016).

Figure 28.10 shows the simulated evolution of the FF and NF profiles of the GG-NBS device as a function of the output power. The relatively smooth profiles of the FF and NF at low power evolve when the injection increases to a more structured profile with an increasing number of more and more distinguishable lobes. The FF width at $1/e^2$ decreases slightly when the power increases, while the $1/e^2$ NF width at waist remains almost invariant, in agreement with what has been experimentally observed (Fiebig et al. 2009). These behaviors yield an almost invariant low value of $M^2(1/e^2)$. However, the value of M^2 (second moment) significantly increases with the power, mainly due to the tiny side lobes below the $1/e^2$ level in the NF at waist (see inset in Figure 28.10b). These differences will be commented later in Section 3.5. The agreement between the appearance and the evolution of the FF and NF lobes in simulation and experiments provides support for the use of the simulation tool to provide a physical understanding of the origin of these lobes in devices without beam spoilers.

Aiming at this, for an output power level of 0.26 W, Figure 28.11 shows gray-scale plots of the forward (Figure 28.11a) and backward (Figure 28.11b) propagating photon densities, normalized to their maximum value at each cavity position. The side lobes that are already apparent at the beginning of the tapered section, propagate toward the front facet, and finally result in the multilobed NF pattern shown in Figure 28.10c. During the backward propagation (Figure 28.11b), the highest intensity side lobes run away the tapered region where they extinguish without reaching the RW section. However, the backward field entering the RW section is not perfectly filtered and a fraction of it is diffracted by the RW section aperture producing side lobes in the field that reaches the back facet. This residual field at the sides of the RW section is reflected by the back facet and interferes in the tapered section with the forward field arising directly from the RW section, thus producing the multiple peaks observed in the beam characteristics.

The lack of a complete filtering in the RW section is more important at high power, as the intensity of the backward field increases and optically pumps the sides regions around the RW, thus reducing the absorption. This effect is further illustrated in Figure 28.12, where we have plotted the forward and backward photon densities (Figure 28.12a) and the carrier density (Figure 28.12b) at the interface between the



(a) (b) (c)

FIGURE 28.10 (a) Far field, (b) near field at waist, and (c) near field at the front facet for the GG-NBS device at three power levels, $P_{out} = 40$ mW (solid), $P_{out} = 260$ mW (dashed), and $P_{out} = 393$ mW (dotted). The inset in (b) is a magnification emphasizing the side lobes far from the axis appearing at $P_{out} = 260$ and 393 mW.

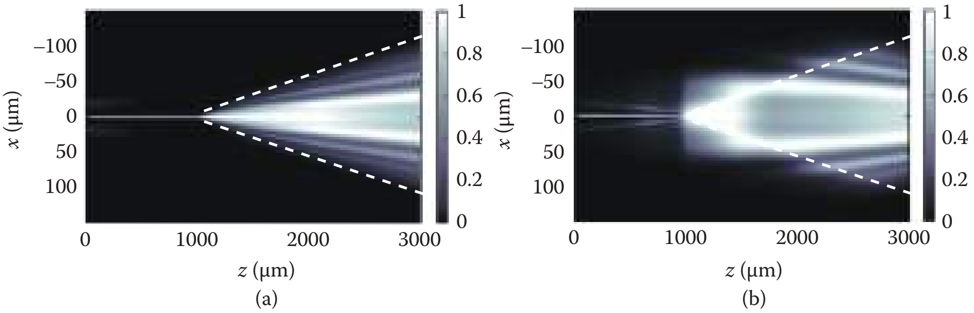


FIGURE 28.11 Normalized (a) forward and (b) backward optical field intensity inside the cavity at each z slice for the GG-NBS device, when operated at high power (P_{out} = 260 mW). The white dashed lines indicate the pumped tapered region.

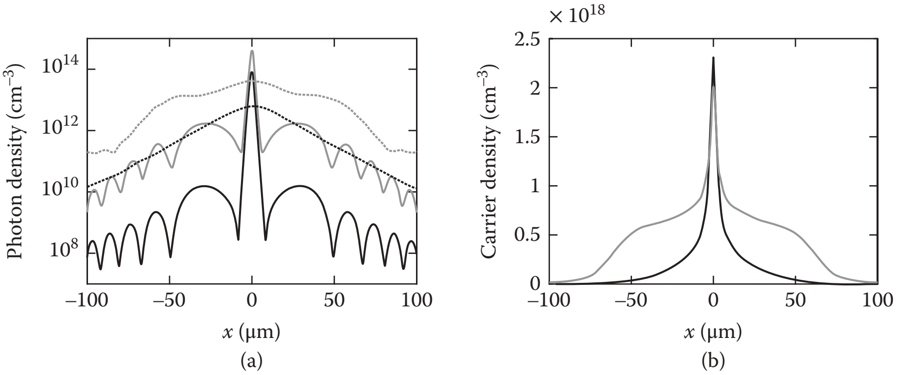

FIGURE 28.12 (a) Forward (solid) and backward (dotted) photon densities and (b) carrier density profiles at the interface between the RW (2.5μm wide) and tapered sections for the GG-NBS device at two output powers P_{out} = 40 mW (black), P_{out} = 260 mW (gray).

RW and tapered sections at two power levels. At low power, the side lobes of the forward field are around 40 dB below the main lobe in the RW (Figure 28.12a) and therefore, this results in a single-lobed NF at the facet (see Figure 28.10c). The backward field at the sides of the RW is low and therefore the induced carrier density (Figure 28.12b) is far below transparency; in consequence, this region is highly absorbent. However, at medium and high injection levels, the backward field intensity is high enough for pumping the sides of the RW to a carrier concentration close to transparency (Figure 28.12b), thus decreasing their absorption. As a result, the forward field intensity at the side lobes becomes only around 20 dB lower than the maximum (Figure 28.12a) giving rise to the multilobed profile obtained at medium and high power level.

Our previous simulations of GG tapered lasers without beam spoilers have shown the same trends as the experimental results (Borruel et al. 2004a; Odriozola et al. 2009), but the quantitative agreement is not as good as we have found in tapered laser with beam spoilers. Furthermore, the maximum output power with numerical convergence in the simulations is usually lower than the measured maximum power. We attribute these discrepancies to the limitations of our steady-state single-frequency model. We think that in the real device, there is a complex dynamics of the different lateral modes giving rise to rapidly varying NF and FF patterns. As the measured NF and FF patterns are temporal averages, it is expected that the narrow and pronounced lobes would average resulting in smoother profiles. In fact, the lack of convergence in the simulations is due to different shapes and positions of the lobes after subsequent round-trips, yielding a stable output power but a different field profile after each iteration. This is illustrated in Figure 28.13, where we have plotted the NF at the facet after two consecutive round-trips for simulation conditions in which a stable solution is not found. The averaging of the field intensity after different roundtrips would produce less pronounced lobes as they appear in the experimental results.

28.3.4 Narrow Index-Guided Tapered Laser

The IG device analyzed in this section is representative of narrow IG tapered lasers. Significant differences with respect to the behavior of large angle GG devices arise from the fact that the single lateral optical mode launched by the RW section does not just expand by free diffraction into an injected tapered region designed to match the free diffraction angle. Instead, the beam is guided in a narrow tapered section defined by the refractive index step, where injection takes place.

The gray-scale plots of Figure 28.14 are illustrative of the forward and backward beam propagation in the IG device at low power (notice the different lateral dimension with respect to the corresponding plots for GG devices). The forward beam expands preserving its shape, with most of the power (99.8% at $z = 2$ mm) inside the guiding region (Figure 28.14a). The propagation of the backward field is determined by a combination of competitive phenomena: diffraction, gain and index guiding, and reflections at the waveguide interface, resulting in a multilobed profile (Figure 28.14b). The index guiding, as well as the relatively small taper angle, produces a beam entering the RW which is narrower than that of the GG devices, hence reducing the taper losses. The RW section acts again as a spatial filter, and the beam recovers its original single-mode shape after a complete round trip.

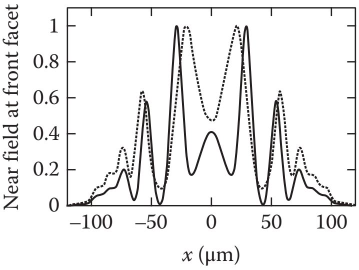

FIGURE 28.13 Example of the simulated NF profiles at the facet for two consecutive iterations of a simulation of the GG-NBS device under conditions in which a stable solution is not found.

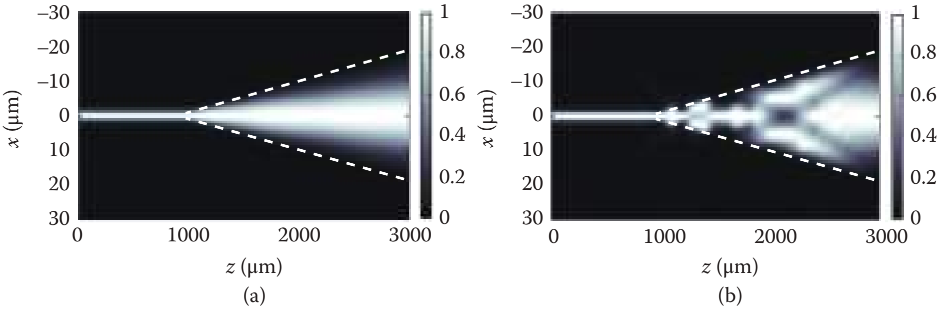

(a)

(b)

FIGURE 28.14 Normalized (a) forward and (b) backward optical field intensity inside the cavity at each z slice for the IG device, when operated at very low power ($P_{\text{out}} = 40$ mW). The white dashed lines indicate the pumped tapered region and the index step.

The main effect degrading the beam quality of IG tapered lasers is carrier-induced lensing and self-focusing, similar to the effect analyzed in Section 28.3.2 for GG devices, but with important differences. Figure 28.15 shows the simulated evolution of the FF and NF profiles of the IG device as a function of the output power. Both the profiles as well as the evolution with power are completely different than those of the GG devices shown in Figures 28.9 and 28.10. At very low power (40 mW), since the beam expands in the tapered section covering almost all the guiding region, the simulated FF width at $1/e^2$ is $\theta_{out} = 3.28°$, close to 3.34°, the value resulting from applying Snell's law to the taper angle. In consequence, the beam is clearly astigmatic (204 μm). But the picture changes dramatically when increasing the power: the carrier lensing reduces the width of the beam at the output facet down to sizes for which diffraction effects become relevant, and consequently, the angular width of the FF patterns increases with the output power while the NF at waist and the NF at the facet narrow. In addition, the carrier lensing also produces an almost collimated beam inside the cavity (see Figure 28.16). Therefore, the virtual source position shifts toward the output facet and even beyond, giving rise to a fast decrease of the astigmatism to zero or even to negative values. The evolution of the beam inside the tapered region, as a consequence of the carrier-induced graded index profile (Figure 28.16), resembles that of a graded-index lens or an optical fiber. The strong SHB at high power produces a self-focusing of the beam leading to saturation of the output power, as will be shown in the next section.

28.3.5 Comparison between Devices

In this section, the main performance parameters of the three simulated devices are comparatively analyzed. Figure 28.17a shows the P–I characteristics, and Table 28.3 summarizes the main parameters

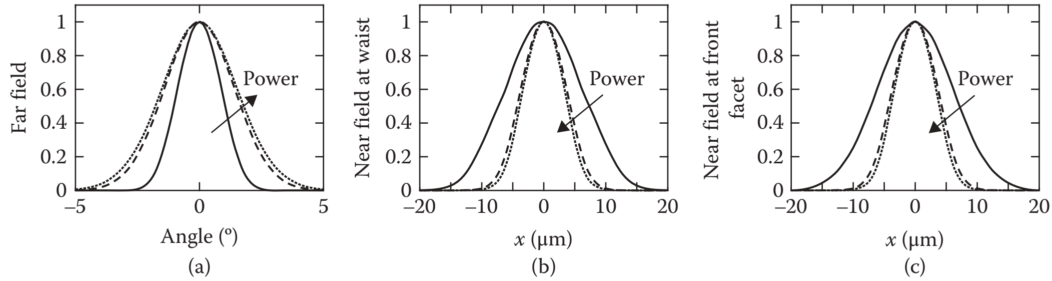

FIGURE 28.15 (a) Far field, (b) near field at waist, and (c) near field at the front facet for the IG device at three power levels, $P_{out} = 40$ mW (solid), $P_{out} = 623$ mW (dashed), and $P_{out} = 912$ mW (dotted).

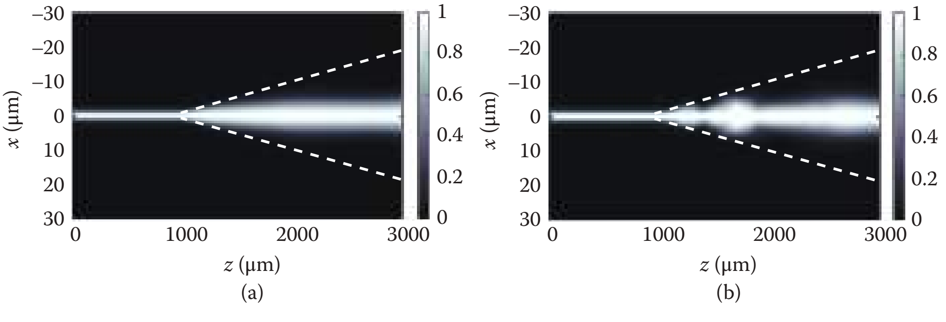

FIGURE 28.16 Normalized (a) forward and (b) backward optical field intensity inside the cavity at each z slice for the IG device, when operated at high power ($P_{out} = 912$ mW). The white dashed lines indicate the pumped tapered region and the index step.

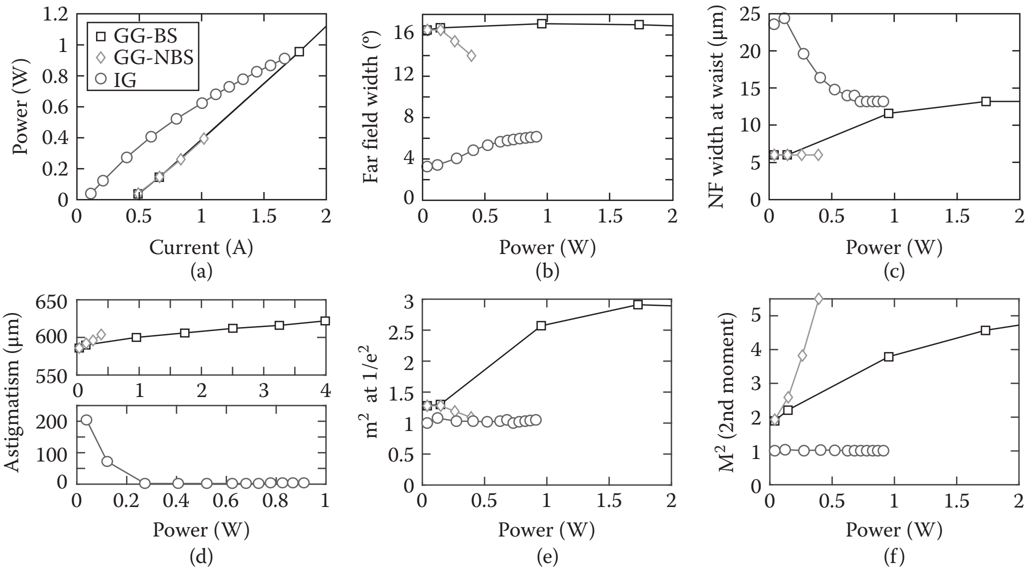

FIGURE 28.17 Comparison of the figures of merit for the different devices: GG-BS (squares), GG-NBS (diamonds), and IG (circles). (a) Power versus current characteristics, (b) far-field width versus power, taken at FWHM (open) and $1/e^2$ (closed), (c) near field at waist width versus power, taken at FWHM (open) and $1/e^2$ (closed), (d) astigmatism versus power, (e) M^2 $(1/e^2)$ versus power, and (f) M^2 (FWHM) versus power.

TABLE 28.3 Parameters Extracted from the Simulated P–I Characteristics of the Three Devices

	GG-BS	GG-NBS	IG
Threshold current (A)	0.43	0.43	0.066
Threshold current density (A/cm^2)	198	197	156
Slope efficiency at threshold (W/A)	0.625	0.625	0.85
Taper losses (cm^{-1})	8.6	8.6	5.4

extracted from these results: the threshold current and threshold current density, the slope efficiency, and the taper losses. The threshold currents of the GG-BS and GG-NBS devices are similar and much higher than that of the IG device, as expected from the comparison of the device area; however, the threshold current density of the IG device is lower, due to the lower taper losses. The taper losses at threshold can be estimated from the simulation results by considering the threshold current density and the modal gain versus current density characteristic, and taking into account the mirror and the internal losses. Values of 8.6 and 5.4 cm^{-1} are obtained for the GG and IG devices, respectively, the lower value for the IG device due to the better matching of the backward field. This difference in the taper losses is also the reason for the higher slope efficiency of the IG device. However, the strong narrowing of the beam in this device due to carrier lensing makes the slope efficiency to decrease when the injection increases (see Figure 28.17a).

Figure 28.17b and c shows the evolution of the widths of the FF and of the NF at waist (at $1/e^2$), respectively, for the three simulated devices. At low power, the FF widths of the GG and IG devices are 16.5° and 3.3°, respectively, not far from the expected value for a Gaussian beam applying Snell's law, as previously discussed. On the contrary, the NF at waist is much wider in the case of the IG device, as expected from its lower divergence. The astigmatism at low power (Figure 28.17d) is also quite different, with the virtual source (or beam waist) located at a distance behind the front facet $z_{vs} = 590$ μm and $z_{vs} = 204$ μm for the GG and IG devices, respectively. The former value is close to $L_{tap}/n_{eff} = 599$ μm, the expected value for the free diffraction of a beam at the output of the RW; the latter is lower, even at very low power, due to the index-guiding mechanism.

As previously mentioned, the devices show clear differences in the evolution of their beam characteristics when power increases. In summary: in the GG-BS device, the FF width at $1/e^2$ is approximately constant and the waist increases, in the GG-NBS the waist is constant and the FF width decreases, and in the IG device the FF broadens and the waist remains constant. These differences are also reflected in the behavior of the astigmatism (Figure 28.17d), which increases with the power for the GG devices while decreases for the IG laser. Finally, the evolution of $M^2(1/e^2)$ and M^2 (second moment) for the three devices is compared in Figure 28.17e and f, respectively. The best beam quality is obtained for the IG device with a M^2 (second moment) close to the unity, indicating a diffraction-limited beam. When power increases, the increase of the value of M^2 (second moment) is much faster for the GG-NBS device than for the GG-BS laser due to the fact that the multiple lobes in both the FF and the NF at waist of the first one strongly affect the second moment widths. On the contrary, the value of $M^2(1/e^2)$ is very low, close to the unity, for the GG-NBS device, even at the highest power in the simulations. Similar discrepancies between M^2 (second moment) and $M^2(1/e^2)$ have been reported experimentally for GG devices without beam spoilers (Fiebig et al. 2009).

28.4 Summary

We have presented an overview of the current state of the art in the modeling of high-power tapered lasers, with a detailed description of our steady-state single frequency quasi-3D simulation tool. We have explained the calibration procedure required for making meaningful comparisons with experiments and using the simulator as a predictive tool. The capabilities of the model have been illustrated by comparing the beam properties of three different types of tapered lasers emitting at 1060 nm: GG with beam spoilers, GG without beam spoilers, and narrow IG. The simulations reproduce the different behaviors experimentally observed in the three types of device and can be used for a better understanding of the interaction between carriers and photons that determines the operation of tapered lasers.

High-power laser diodes first gained interest as pump sources for solid-state lasers, with cost/watt and reliability as the primary market drivers. In recent years, new markets have been opened by increases in the brightness of the laser diode sources and by advances in the optical systems for beam shaping and combining. The work in this chapter is motivated by the development of high-brightness laser diodes for direct-diode laser systems targeting industrial applications and a desire to illustrate the important role of laser simulation tools at both the device and system level. Traditionally, welding and sheet metal cutting are the most lucrative industrial laser markets, but they are also the most demanding in terms of brightness. Laser additive manufacturing processes, such as selective laser melting, are also quickly becoming a reality and allow the fabrication of structures that cannot be made by traditional means. Their automated nature is opening the door to new manufacturing paradigms.

Direct-diode laser systems for industrial applications combine the beams from many individual laser diodes (or diode arrays) to couple them into an optical fiber for delivery to the target. The role of the optical system is to combine the individual beams without losing their brightness. High-power direct-diode lasers rely on multiple beam-combining methods, including incoherent or "side-by-side" beam combining, polarization multiplexing, and spectral beam combining. The first commercial kW-class direct-diode laser system used an external cavity to stabilize the wavelengths of, and spectrally combine, the beams of a large number of broad-area (BA) lasers to couple a 1 kW beam into a 200 μm fiber (Huang et al., 2011). The brightness of the final system is ultimately limited by the brightness of the individual sources.

All beam-combining techniques couple light back into the laser diodes—deliberately, as in external wavelength stabilization and spectral beam combining, or accidentally due to reflections off the optics. This optical feedback is known to affect both the beam quality and the degradation of the laser diodes (Hempel et al., 2013), but little has been published on how this feedback affects the operation of the laser. As the power and performance requirements increase, the role of external optical feedback is becoming increasingly interesting.

This chapter focuses on the impact of external optical feedback on high-brightness laser diodes. We start by introducing the common beam quality metrics used for lasers and briefly review the diode laser technologies most commonly considered for high-brightness direct-diode laser systems, before focusing on the tapered laser and showing why they are strong contenders for future high-power direct-diode laser systems. We then describe the coupling of our continuous wave (CW) simulation tool, *Speclase*, to commercial optical design tools to self-consistently simulate high-brightness diode lasers with external optical feedback. We conclude with a case study exploring the impact of unintentional feedback on the excitation of higher order vertical modes and lateral beam quality in a large optical cavity (LOC) tapered laser.

29.1 Power Scaling and the Role of Beam Quality

The purpose of the beam-combining optics in a direct-diode laser is usually to couple the highest amount of power from the individual laser diode sources into the end of an optical fiber. The brightness of the combined beam (units = W cm^{-2} sr^{-1}) limits the power that can be coupled into the delivery fiber and depends on the brightness of the individual diode sources.

Metrics such as the beam parameter product (BPP) Q or beam propagation factor M^2 are common metrics used by manufacturers and industries to specify the beam quality of both the individual laser diode and direct-diode laser systems. The BPP is the product of beam radius (measured at the beam waist) and the half-angle beam divergence:

$$Q = \omega_0 \times \theta_{\text{div}}, \tag{29.1}$$

where ω_0 is the beam radius measured in millimeter and θ_{div} measured in milliradian and Q is the BPP measured in mm·mrad. The BPP allows optical designers to determine the number of individual beams that can be imaged onto the end of a fiber with a fixed diameter (physical aperture) and maximum acceptance angle (numerical aperture). The power coupled into the fiber also depends on the power of the combined beam (and hence of the individual emitters). The brightness (units: W cm^{-2} sr^{-1}) is defined as

$$B = \frac{P}{\pi^2 Q^2} = \frac{P}{\lambda^2 M^2} = \frac{P}{\lambda^2 M_x^2 M_y^2}, \tag{29.2}$$

where P is the laser output power, Q is the BPP, λ is the wavelength and M^2 is the beam propagation factor. M^2 is another measure of beam quality as defined by ISO 11146. The beam quality metrics, M^2 and Q are related by Equation 29.2, as shown in Table 29.1 for $\lambda = 975$ nm. (A detailed discussion of beam quality metrics is in Chapter 28.)

Figure 29.1 shows the power and beam quality needed for different industrial laser applications. The dashed lines show the improvement in laser diodes (and direct-diode laser systems based on them) between 2000 and 2014. A laser with a power of 20 W and $M^2 \sim 20$–30 (e.g., a good BA laser diode [Thestrup et al., 2003]) is suitable for printing and material processing, but not for additive manufacturing, welding, or cutting. Conversely, a laser with a power of 10 W and $M^2 < 1.5$ (e.g., a good tapered laser diode [Fiebig et al., 2008]) is suitable for sheet metal drilling, marking, additive manufacturing, welding, and cutting of metal.

TABLE 29.1 Correspondent Values of M^2 and Q

5.0	1.6
10.0	3.1
20.0	6.2
30.0	9.3

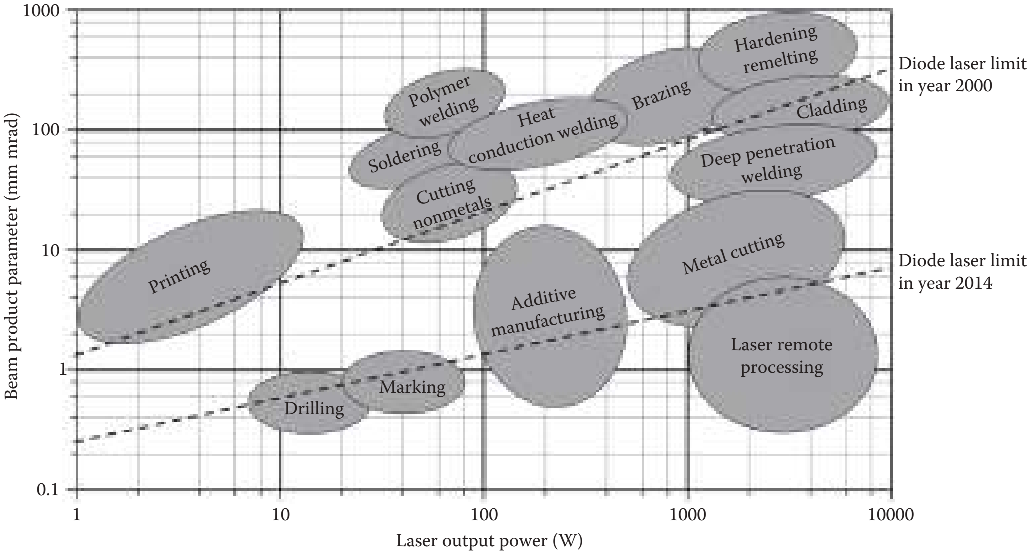

FIGURE 29.1 Beam parameter product versus laser power for different applications.

29.2 High-Brightness Laser Diode Sources

Laser diodes for the most demanding industrial applications should have high brightness (e.g., $P \geq 10$ W, $Q < 1$ mm·mrad, or $M^2 < 3$) and high-power conversion efficiency (PCE) (e.g., $PCE \geq 55\%$). The sources (and their performance) should be reliable and insensitive to reflections.

29.2.1 Vertical Cavity Design

The vertical cavity design of a laser diode for efficient, high-power operation in an external cavity is more complicated than that of an isolated high-power laser diode. First, a wide vertical mode profile (vertical near-field pattern) is needed for efficient external cavity coupling and reduced alignment tolerance. This also increases the tolerance to "smile" (a bend in the horizontal axis of a laser bar, which introduces pointing errors in the slow axis) across a laser array and allows the use of simpler, less costly optics. Second, the excitation and lasing of higher order vertical cavity modes by external optical feedback must be suppressed; photons coupled from external cavity will lead to stimulated emission. Third, a narrow vertical far-field divergence is needed to minimize the impact of optical aberrations, thereby improving the cost and performance of the optical system. Finally, the need for high-PCE means that Joule heating and free-carrier absorption (FCA) play critical roles in the vertical cavity design (Larkins et al., 2014).

High-brightness laser diodes typically use LOC waveguides to produce a wide vertical near-field pattern and narrow far-field divergence pattern. The LOC cavity reduces the power density at the facet (increasing the mirror damage threshold) and reduces the vertical confinement factor (reducing carrier-induced lensing). The confinement factor is the ratio of modal power contained in the active area to that contained in the structure. Below is the definition of the vertical confinement factor:

$$\Gamma(y) = \frac{\int_{-d/2}^{+d/2} E(y)^2 \mathrm{d}y}{\int_{-\infty}^{+\infty} E(y)^2 \mathrm{d}y}. \tag{29.3}$$

The LOC waveguide also facilitates external cavity feedback (e.g., for wavelength stabilization and/or lateral mode filtering), but also makes the device more sensitive to parasitic reflections.

As the LOC waveguide thickness increases beyond a certain point, the influence of the cladding layer diminishes and the waveguide is formed by the index contrast of the active region and the waveguide. Further increases in waveguide thickness raise the Joule heating and FCA losses, but do not significantly increase the near-field width or reduce the far-field divergence. Wider near-field patterns can be achieved (with thinner, more efficient waveguides) using other methods, including low-index quantum barriers to reduce the index contrast between the active region and the waveguide (Wang et al., 2013); or high-index optical traps to draw the field profile out into the waveguide (Buda et al., 1999).

LOC waveguides support multiple vertical modes, but, in the absence of external feedback, lasing is limited to the mode that reaches threshold first. When operated in a system with external feedback, however, back coupling to higher order modes can cause them to lase. Even if the higher order modes do not lase, the additional stimulated emission and FCA can reduce the laser's efficiency and increase self-heating. External feedback also affects the reliability of high-power laser diodes (Tomm et al., 2011). Thus, feedback is becoming important as diode laser systems grow in power and complexity.

The suppression of higher order vertical modes becomes more challenging when the laser is operated in an external cavity, where the optical feedback also excites the higher order vertical modes. First, as little power as possible must couple into the higher order vertical modes. Second, the higher order vertical modes must be prevented from reaching threshold. This can be achieved by engineering the laser cavity to make the confinement factors of higher order modes much lower than that of the fundamental mode, so that their modal gain is lower. Accordingly, we define a new figure of merit for modal discrimination (MD):

$$\mathrm{MD} = \Gamma(1)/\Gamma(n), \tag{29.4}$$

where Γ is the optical confinement factor and n refers to the higher order mode with the largest confinement factor. MD_n can also be used to describe the MD of a particular mode n. (*Note:* Propagation loss is neglected in MD, as it depends on the doping profile and operating bias—which are usually optimized *after* the initial cavity design.)

Power from the external cavity can be coupled into the higher order modes, even if they do not reach threshold. The modal gain of the higher order modes can also be reduced by increasing their propagation loss—either by FCA or by substrate leakage. Damping of the higher order vertical modes also reduces the total amplified spontaneous emission (ASE) from these parasitic modes. ASE and gain of light coupled into these modes do not contribute to the fundamental mode. Instead, they act as current leakage paths, contributing to self-heating and reducing the PCE.

LOC laser structures based on both the low-index quantum barrier and the high-index optical trap approaches were optimized (optically and electrically) for operation with external optical feedback (Larkins

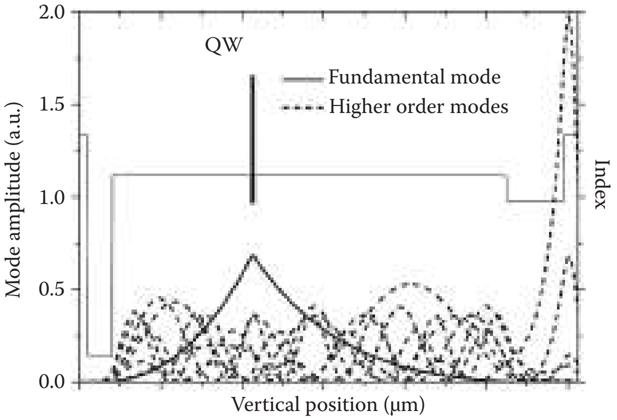

FIGURE 29.2 Vertical mode profiles in the ELoD2 LOC laser structure.

TABLE 29.2 Confinement Factor and MD Values for All Vertical Modes in ELoD2 Structure

et al., 2014). The tapered lasers in this chapter are based on the ELoD2 vertical cavity with low-index quantum barriers (Crump et al., 2013c). This structure supports eight vertical modes, as shown in Figure 29.2. Their confinement factors and MD are given in Table 29.2.

29.2.2 Lateral Cavity Design

State-of-the-art high-power lasers need a large output power, high PCE, and excellent beam quality. Ridge waveguide (RW) lasers can produce a diffraction limited beam (single lateral mode), but have only achieved output powers of 1.6 W (Yang et al., 2004). Flared RW lasers have achieved a maximum power of 3 W and kink-free power of 2.2 W (Sverdlov et al., 2013). To achieve higher output powers, the laser diode needs a larger gain volume (energy reservoir). This can be most easily achieved by increasing the emitter width, which has the added benefit of lowering the power density at the facet—thereby increasing the catastrophic optical mirror damage (COMD) threshold.

Slab-coupled optical waveguide laser (SCOWL) diodes (Donnelly et al., 2003) use a shallower RW etch to allow the beam profile to expand laterally in the "slab" below. They have been used as high-brightness sources for power scaling by spectral beam combining (Huang et al., 2009). SCOWLs have good beam quality and low astigmatism, but their limitations are similar to those of the flared RW laser and comparatively low power (2.8 W) (Huang et al., 2007) limits their single-emitter brightness.

BA diodes have achieved powers of 29 W, reliable operation at 20 W, and record PCE (76%) at 0°C. BA lasers have simultaneously achieved high power *and* high PCE at 300 K (14.5 W, PCE >60%)

(Crump et al., 2009, 2013a). Their main limitation is their poor slow-axis beam quality ($M^2 \sim 20$–30) (Knigge et al., 2005).

Lim et al. used simulations to investigate the dependence of the beam quality of BA lasers on cavity length and width as a function of power (Lim et al., 2005). Lim's work showed that the brightness of gain-guided BA lasers improved with reduced cavity width and increased cavity length—establishing a new basis for the development of narrow broad-area (NBA) laser diodes. Since then, NBA laser diodes have received increasing attention (Crump et al., 2013b; Decker et al., 2014; Skidmore et al., 2016), with powers of 7.5 W with $Q_{\text{slow axis}} = 1.8$ mm·mrad and high efficiency (PCE = 57%) (Crump et al., 2013b). Despite the impressive performance of NBA laser diodes, they still fall short of the desired performance for the most demanding applications.

The beam quality of BA lasers can also be improved using asymmetric feedback to reduce the threshold of a particular higher order lateral mode (Pillai and Garmire, 1996; Thestrup et al., 2003; Wolff et al., 2003; Lang et al., 2008), exploiting a concept previously demonstrated for phase-locked laser arrays (). However, the usefulness of asymmetric feedback stabilization for high-brightness operation still needs to be demonstrated—in particular, whether they can maintain their high beam quality and PCE at high power

Tapered laser diodes have received great interest, since they combine the lateral mode confinement/filtering of the RW laser and the large gain volume of the BA laser. Thus, tapered lasers are able to produce a high output power (12 W) with high beam quality ($M^2 < 1.2$) and exceptional brightness ($B = 1.1$ GW·cm^{-2} sr^{-1}) (Walpole et al., 1992; Kelemen et al., 2005; Sumpf et al., 2010). This comes at the expense of lower PCE (43%–55%) and power-dependent "wandering" astigmatism (Dittmar et al., 2006; Fiebig et al., 2008). Thus, the tapered laser is promising for high-brightness direct-diode laser systems. The main challenges are to control their beam quality degradation at high power and to understand the role of optical feedback.

29.2.3 Evolution of Lateral Beam Quality of High-Brightness Tapered Laser Diode

The tapered laser diode comprises RW and tapered amplifier (TA) sections. The RW supports a single lateral mode, to inject a diffraction-limited beam into the amplifier. It also filters out higher order lateral modes from the backward traveling fields it receives from the tapered section. The TA provides a large gain volume with a large output aperture. The taper angle is chosen to match the diffraction angle from the RW (Pearson et al., 1969; Walpole et al., 1992), allowing the field to expand in the taper to produce a smooth output field profile, as illustrated in Figure 29.3.

A nearly diffraction-limited lateral beam is obtained from conventional tapered lasers at low to moderate power, but the beam quality degrades rapidly at high power. This beam quality degradation reveals degradation of the RW filter performance due to gain saturation inside the RW and absorption bleaching by the backward traveling fields outside of it (Sujecki et al., 2003; Kaunga-nyirenda et al., 2014; Larkins et al., 2014, 2016). The absorption bleaching (due to band filling by the generated carriers) renders the material transparent and allows the backward traveling fields outside the RW to reach the rear facet, where they are reflected and reenter the TA, as shown in Figure 29.4

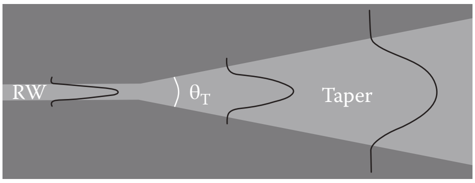

FIGURE 29.3 Schematic diagram of a tapered laser, showing the adiabatic expansion of the beam in the taper.

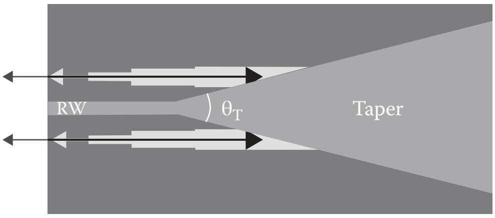

FIGURE 29.4 The beam outside the ridge waveguide (RW) bleaches the absorption in these regions, allowing the reflected beam from the back fact to travel back and couple into the tapered amplifier (TA)

These unfiltered fields create high-spatial-frequency features in the near-field pattern. These high-frequency features or filaments are caused by the propagation and diffraction of the backward-traveling fields in the absorption bleached regions outside the RW (Lim et al., 2012; Larkins et al., 2014). This diffraction is primarily due to the diffraction of the backward propagating fields that are *not* coupled into the RW. Figure 29.5a shows the back propagating field in a 975 nm-tapered laser at $I = 15$A. The backward propagating fields are amplified in the taper and gain guided at the edges of the taper to form a high-intensity spot where the RW joins the TA. The fields diffracting from this spot are clearly visible alongside of the RW. Figure 29.5b shows the backward propagating fields from this high-intensity spot in the absence of index and gain-guiding effects. The field pattern agrees with the corresponding region in Figure 29.5a (inside the white box)—except that the central lobe widens due to the absence of index guiding by the RW. In Figure 29.5c, only the central field lobe (the lobe that couples into the RW) was back propagated, while in Figure 29.5d only the outer lobes of the spot were propagated. Figure 29.5c and d shows that only the fields *not* coupled into the RW give rise to the diffraction pattern—and thus, for the absorption bleaching and beam quality degradation.

Finally, spatial hole burning at the center of the taper and electrical over-pumping at the edges creates high carrier densities and gain at the edges of the taper, as seen in quantitative intracavity spontaneous emission imaging measurements (Bull et al., 2004, 2006). Amplification and carrier-induced waveguiding in these regions cause the "batman" ears in the near-field pattern and amplify/guide the backward fields that degrade the RW filter performance (Williams et al., 1999; Sujecki et al., 2003) Different techniques have been suggested to overcome the degradation of beam quality, such as reducing the front facet reflectivity, using beam spoilers or using a longer RW section. Figure 29.6 shows the impact of reducing front facet reflectivity on the total photon density distribution (i.e. the sum of densities of both the forward and backward traveling waves). These techniques all reduce the backward traveling field and associated absorption bleaching. At the emitter powers sought for high-brightness direct-diode lasers (>10 W), however, these techniques are insufficient. (Beam quality degradation in tapered lasers is also discussed in Chapter 28.)

An integrated distributed Bragg reflector (DBR) mirror at the end of the RW provides a solution with better high-power performance. The rear facet of the laser must be antireflection (AR) coated for the DBR to work properly. The DBR (and AR-coated facet) act a spatial filter, allowing the backward traveling fields in the regions outside the RW to exit the rear facet, as illustrated in Figure 29.7. In order to study the spatial filtering performance of the RW section, and understand how the DBR RW section improves the spatial filtering performance of the conventional tapered laser, we define the RW filter response as the ratio of the forward and backward propagating field distributions at the interface between RW and TA sections:

$$H_{\mathrm{RW}} = \log_{10}\left[\frac{P_{\mathrm{forward}}}{P_{\mathrm{backward}}}\right]. \tag{29.5}$$

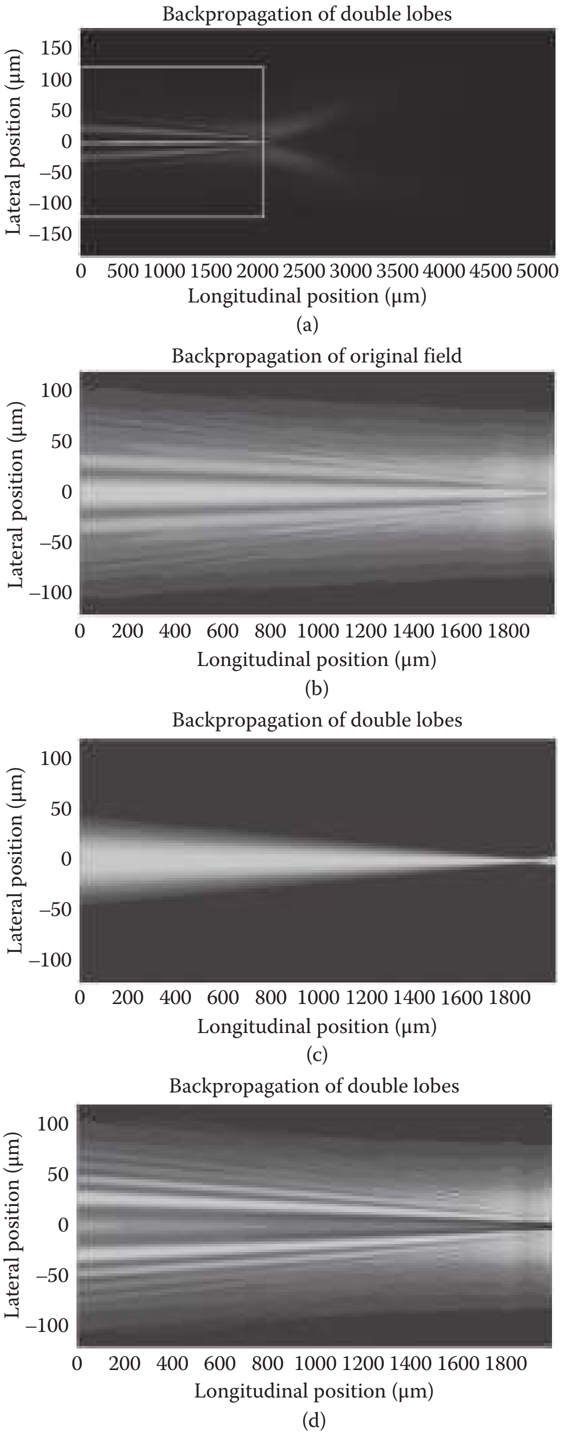

FIGURE 29.5 (a) Backward propagating field in 975 nm tapered laser ($I = 15$ A) for converged simulation. FIGURE 29.6 Impact of front facet reflectivity on the shape of forward and backward traveling waves. Both figures (a and b) show the total photon density distribution (forward + backward).

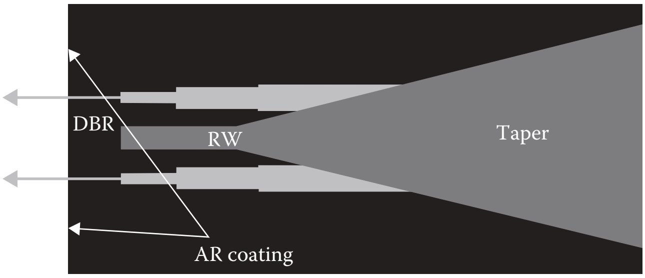

FIGURE 29.7 Schematic diagram of the DBR-tapered laser, showing how the back-propagating beams outside of the RW are allowed to leave the structure, instead of coupling back into the TA.

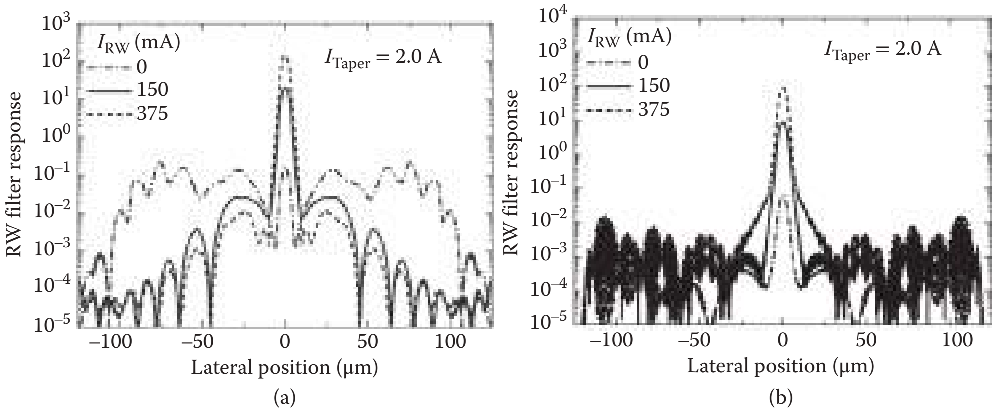

FIGURE 29.8 RW filter performance comparison of conventional (a) and DBR (b) tapered lasers.

Figure 29.8 compares the RW filter responses of DBR and conventional tapered lasers with dual contacts for a constant taper current as a function of RW current. In the conventional tapered laser, the fields in the RW are not amplified at the lowest RW current, but those outside the RW propagate and are reflected—reducing the performance of the RW filter. In the DBRtapered laser, these fields are not reflected and exit

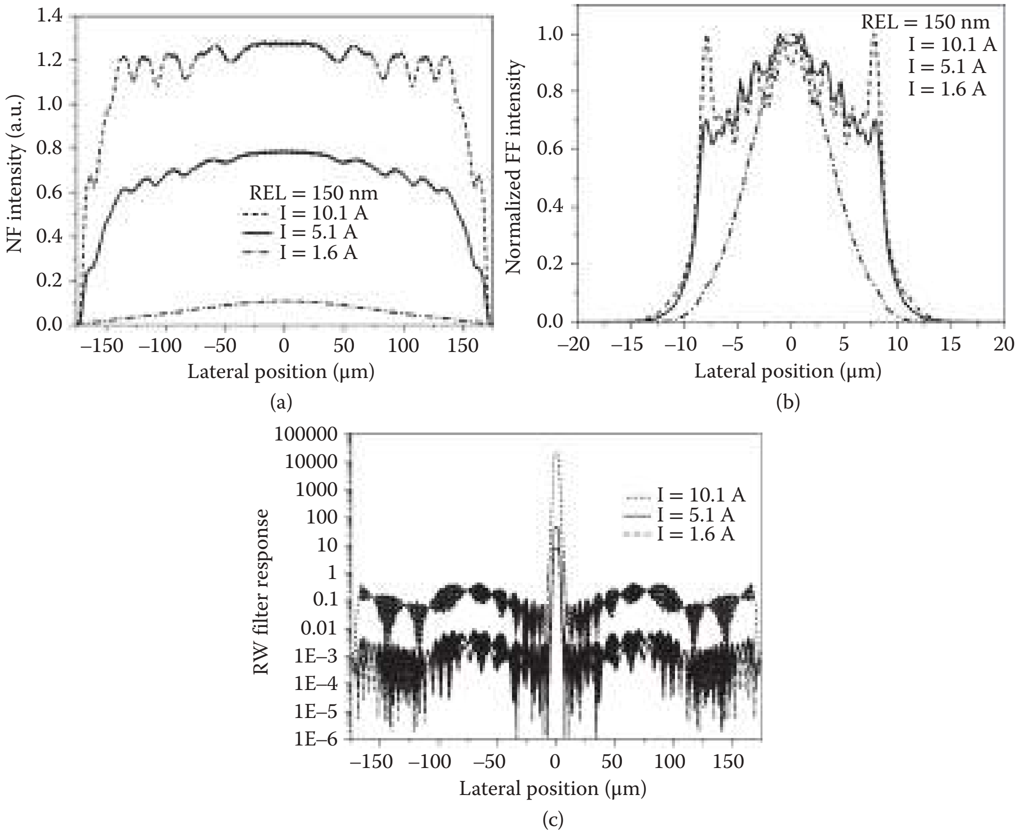

FIGURE 29.9 Evolution of near-field (a), far-field (b) and RW filter response (c) with current.

through the AR-coated rear facet. Thus, the filter performance of the DBRtapered laser remains good up to higher powers.

Despite the large performance improvement of the DBR-tapered laser at high powers, $M^2_{\text{2nd moment}}$ still increases with power. To understand this, we studied the evolution of the near- and far-field patterns and the RW response with current, as shown in Figure 29.9.

As the current increases, high spatial frequency features appear in the near-field pattern and grow in strength, causing degradation of the far-field pattern. The appearance of these features correlates with a sudden reduction in the RW filter performance. Furthermore, the RW width and etch depth have little impact on beam quality as seen in Figure 29.10. (Figure 29.10 also shows that $M^2_{e^{-2}}$ [beam radius w_0 in Equation 29.1 is measured at $1/e^2$] is independent of current, while $M^2_{\text{2nd moment}}$ [beam radius w_0 in Equation 29.1 is measured using second moment of area definition, as defined in Chapter 29] provides a more sensitive measure of the changes in the near and far-field patterns.)

Figure 29.11 shows the forward propagating field at the junction of the RW and TA sections. Although the fields outside the RW are small, they will be strongly amplified.

The fields outside the RW section explain the degradation of the filter function (and the changes in the near- and far-field patterns), but there is a problem: *If the backward propagating fields outside the RW all escape through the AR-coated rear facet, then where do these forward propagating fields come from?* The answer lies in the forward propagating photon distribution in Figure 29.12, which reveals a single aperture diffraction pattern—as confirmed by the positions of the nodes in the pattern. Although these simulations assume a simple patterned rear facet reflectivity, the DBR will also produce aperture diffraction.

29.3 External Cavity Laser Simulation

New simulation tools are needed to address the problems posed by high-brightness diode lasers operating in a system context with external optical feedback. The laser diode and the external cavity pose different modeling challenges and require the use of different modeling approaches and software tools. These approaches and tools must be brought together to model the laser diode and the external optical system self-consistently.

29.3.1 Laser Diode Simulation Tool "*Speclase*"

The simulation of high-brightness laser diodes is a challenging task, which requires self-consistent modeling of the electrical, optical, and thermal processes throughout the device (Williams et al., 1999; Lim, 2003; Sujecki et al., 2003; Lim et al., 2009). LOC devices with external feedback bring the additional challenge of simulating fields with different vertical mode profiles and their competition for the available gain.

The simulation of the laser diode is performed with an in-house laser simulation tool, *Speclase* (Lim et al., 2009), for the self-consistent quasi-3D optical, electrical, and thermal simulation of high-brightness laser diodes. *Speclase* uses the two-dimensional (2D) wide-angle finite-difference beam-propagation method (WA FD-BPM) for the optical field propagation in the longitudinal and lateral directions (x–z plane). Bipolar electrical simulations are performed in a series of planes orthogonal to the optical axis (x–y planes), neglecting heat and carrier flow in the z-direction. The electrothermal and optical solvers are coupled through the stimulated emission/absorption and ASE processes and refractive index perturbations (calculated from perturbations of the gain/absorption spectra using the Kramers–Kronig relations).

The optical solver models the spectral behavior of the device by propagating multiple wavelengths and their competition through the spectral-spatial gain distribution. Figure 29.13 shows the flow diagram of *Speclase*. The electrothermal and optical models are solved self-consistently, using an accelerated Fox–Li iterative approach (Agrawal, 1984).

In order to model the excitation and competition of fields with different vertical mode profiles, *Speclase* calculates each of the vertical field distributions and their vertical confinement factors. This allows *Speclase* to calculate the effective index and FCA distributions needed for the 2D propagation of the fields with each of the allowed vertical mode profiles. Figure 29.14 describes the flow diagram of *Speclase* for the simulation of a high-brightness LOC laser diode coupled to an external cavity.

29.3.2 External Cavity Simulation Tool

The modeling of the external cavity requires modeling of free-space optical propagation, including the transmission, reflection, and scattering effects. The optical models used inside the laser diode are not well suited to free-space optical propagation, where Fourier optics (FO) and coherent ray tracing methods are more appropriate. FO models preserve the wave nature of the optical propagation, but the underlying paraxial approximation is best suited to low-divergence beams. Coherent ray tracing is better suited for external cavity laser diodes with large beam divergence. Coherent ray tracing methods are also fast and flexible, making them attractive for modeling complex optical systems. We describe an external cavity modeling tool (*OpticStudio*) based on coherent ray tracing. FO models are also used in this chapter, but do not need wave-ray transformation and are not discussed here.

29.3.3 Coupling of the Laser Diode Simulation Tool and Coherent Ray Tracing Tools

The coupling of the laser simulator and the coherent ray tracing tool for the external cavity is not straight forward, since the light is treated as a wave inside the laser diode, but as rays in the external cavity. Careful analysis of the output beam of the laser diode is needed to produce the input rays for the external cavity model, while maintaining all of the properties of the beam emitted from the laser diode (e.g., near- and far-field patterns, astigmatism). Bidirectional coupling is even more challenging, requiring conversion of the rays back into an optical field distribution, which contains both intensity and phase information.

First, the field data produced by *Speclase* (near-field, far-field and wavelength) must be converted into rays, which represent the laser source in *OpticStudio*. These rays each have a set of attributes: launching coordinates, direction cosines and intensity.

Speclase simulates the lateral field distribution at the facet using 2D WA FD-BPM, so the lateral near-field pattern is multiplied by the associated vertical field profile. The horizontal and vertical far-field patterns are calculated by Fourier transformation:

$$\psi\left(\theta_H\right) = \left(\cos\theta_H\right)^2 \left| \int_{-\infty}^{+\infty} \mathrm{E}(x) e^{j(\sin\theta_H k_0 x)} \mathrm{d}x \right|^2 \tag{29.6}$$

$$\psi(\theta_V) = (\cos\theta_V)^2 \left| \int_{-\infty}^{+\infty} \mathrm{E}(y) e^{j(\sin\theta_V k_0 y)} \mathrm{d}y \right|^2, \tag{29.7}$$

where ψ is far-field profile, θ is the divergence angle, E is the electric field, and k_0 is the wavenumber. Due to the astigmatic nature of the laser beam, the output rays appear to originate from two virtual line sources (nonastigmatic sources have a virtual point source). The output rays must intersect both of these line sources—one for the vertical beam divergence and the other for the horizontal beam divergence. The longitudinal positions of these line sources are obtained by FO back propagation (horizontal line source) and by back tracing the rays (vertical line source). Their transverse positions are the first moments of the near-field patterns

The second challenge is to convert the rays returning to the laser facet back into complex field distributions, taking the ray phases into account. A fraction of the optical energy returned to the laser facet at each lateral position (x) is coupled into the laser for each of the vertical modes supported by the LOC structure, as determined by the overlap integral:

$$\eta_n = \frac{\left| \int_{-\infty}^{+\infty} \left\{ E_{\text{ext}} TE_n^* \right\} \mathrm{d}y \right|^2}{\int_{-\infty}^{+\infty} \left| E_{\text{ext}} \right|^2 \mathrm{d}y \int_{-\infty}^{+\infty} \left| TE_n \right|^2 \mathrm{d}y}, \tag{29.8}$$

where E_{ext} is the distribution of the external field incident on the facet at this lateral position, TE_n is the nth vertical field profile, and η_n is the percentage of the reflected power coupled into cavity mode n. The phase of the coupled field at each position can be calculated by

$$\varphi = \tan^{-1}\left[\frac{Im\left\{ \int_{-\infty}^{+\infty} \left\{ E_{\text{ext}} TE_n^* \right\} \mathrm{d}y \right\}}{Re\left\{ \int_{-\infty}^{+\infty} \left\{ E_{\text{ext}} TE_n^* \right\} \mathrm{d}y \right\}} \right]. \tag{29.9}$$

This process is repeated for the vertical field distributions at each lateral position along the facet. The resulting one-dimensional (1D) field distributions are coherently added to the internally reflected fields and propagated backward within the laser diode using 2D WA FD-BPM. The entire external cavity simulation is repeated using Fox–Li iterations until it converges. Figure 29.15 shows a schematic diagram of the coupling of *Speclase* and *OpticStudio*

29.4 Case Study: The Impact of Unintentional Reflections on a DBR-Tapered Laser

High-brightness tapered lasers are usually characterized and simulated in isolation, without back reflections to degrade the slow-axis beam quality or couple into higher order vertical modes. In this section, we simulate the simple scenario of an LOC tapered laser with fast- and slow-axis beam collimation lenses with the light incident on the end of an uncoated optical fiber ($R = 5\%$), as illustrated in Figure 29.16. The purpose of this study is to:

1. Observe how the feedback affects the power, PCE, and beam quality
2. Observe the impact of the feedback on the excitation of other vertical modes
3. Reveal the impact of self-heating from the excitation of other vertical modes
4. Investigate approaches for suppressing the impact of higher order vertical modes

The laser diode in this study is a 975-nm LOC DBR-tapered laser based on the ELoD2 structure (Crump et al., 2013c), with a 2-mm RW and a 3-mm gain-guided amplifier with a 6° taper. The DBR is represented by a patterned reflectivity ($R = 31\%$ inside the RW, $R = 0.1\%$ adjacent to it). The front facet reflectivity is 1%. Stray external cavity reflections are included using ray splitting and scattering. Figure 29.17 shows the simulated and experimental power and PCE versus current behavior of an ELoD2 BA laser.

High-power laser diodes are often fabricated as linear bar arrays or laser "bars." Laser bars often bend slightly when they are soldered to a heatsink, so that the emitter near-field patterns deviate from a straight line—an effect referred to as "smile." Figure 29.18 shows how "smile" of packaged laser bars displaces the emitters (±0.5 μm) from the axis This displacement causes the beam to propagate through the external

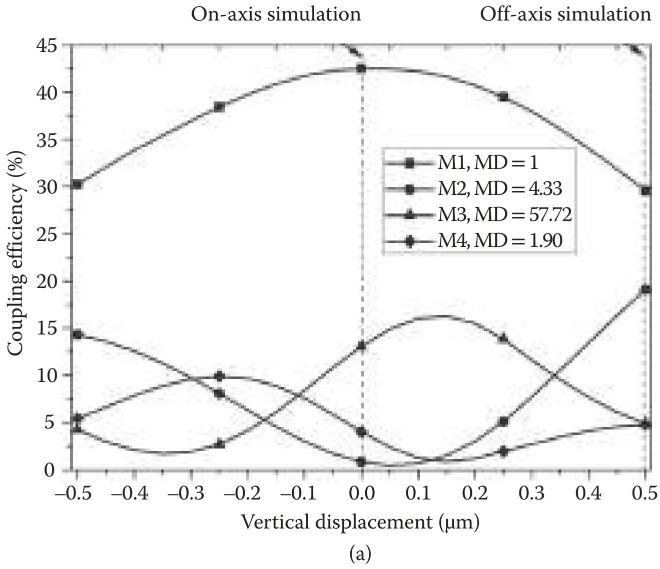
optics at an angle to the optical axis, a phenomenon known as "pointing error" To emulate the impact of "smile" and "pointing error," the emitter position is shifted vertically with respect to the external optical system.

Two external cavity simulations were performed (on- and off-axis) and compared to a stand-alone (SA) simulation (no external feedback). The overlap integrals of the reflected field of the fundamental mode (from the SA simulation) and the cavity modes were calculated to estimate the coupling coefficients versus displacement, as shown in Figure 29.19. These curves show how displacement affects the feedback coupling to the vertical modes. The off-axis simulation was performed for a displacement of +0.5 µm,



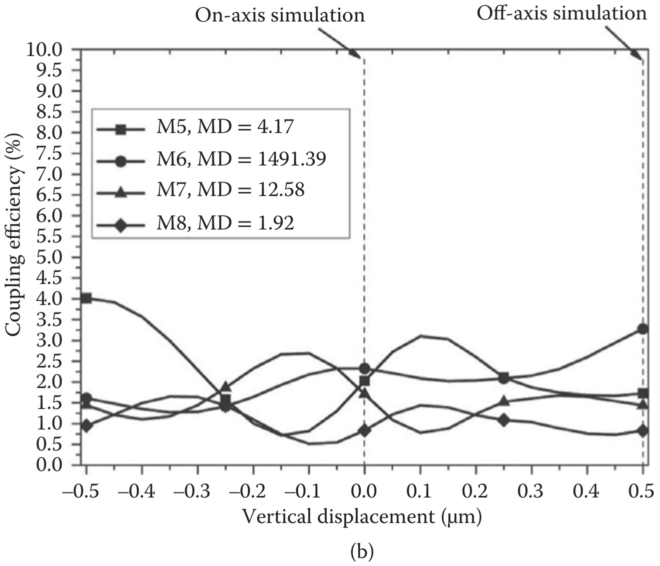


FIGURE 29.19 Impact of smile on external cavity coupling coefficients. Modes 1–4 (a) have coupling >10%, while modes 5–8 (b) have coupling <5%. An off-axis point of interest is displacement = +0.5μm.

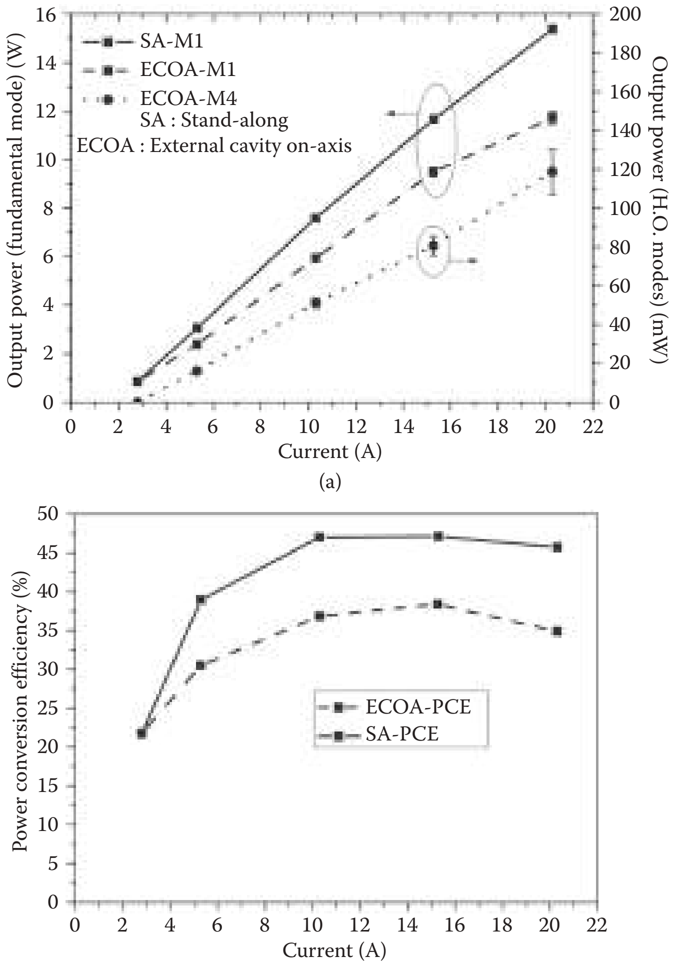
where the fundamental mode coupling coefficient (29.5%) approaches that of a higher order mode (19%, mode 2).

29.4.1 Parasitic Reflections with On-Axis Alignment

Simulations were performed for two different external feedback conditions: no feedback; and feedback to the fields for all of the vertical mode profiles. Simulations were performed at bias currents of 2.5, 5.0, 10, 15, and 20 A. Figure 29.20 shows the power versus current and PCE versus current characteristics to compare the performance of the laser for these two feedback conditions. Our discussion will focus on the performance at a bias current of 15 A, since this produces an output power in the range of interest (10–12 W) for the targeted application.



(a)

(b)

FIGURE 29.20 Simulated power (a) and power conversion efficiency (b) of the tapered laser with and without on-axis feedback.

Figure 29.20 shows that the optical feedback reduces the output power and the PCE. At $I = 15$ A, the on-axis feedback caused the fundamental mode power (mode 1) to drop from 11.67 to 9.49 W, while the PCE fell from 47.1% to 38.4%.

Figure 29.21 compares the near-field patterns (left) and far-field patterns (right) of the on-axis laser for the two feedback conditions. The feedback reduces the output power and increases the modulation depth of the high spatial frequency components in the near-field pattern, as observed experimentally (Hempel et al., 2013; Leonhäuser et al., 2014). The feedback may also lead to excitation and lasing of higher order modes—in this case mode 4.

Figure 29.22 shows the current dependence of the beam propagation parameter M^2 (both the e^{-2} and second moment definitions) for the on-axis external cavity feedback conditions. At $I = 15$ A, the feedback had little effect on $M^2_{e^{-2}}$, but $M^2_{\text{2nd moment}}$ increased from 6.32 to 12.03. This shows that aperture diffraction from the DBR dominates the beam quality degradation.

The total photon distributions (forward and backward propagating) with on-axis feedback are shown in Figure 29.23 for the first four vertical modes. Only modes 1 and 4 are lasing, but light is also coupled into the other modes. Although they do not lase or produce an output beam (and are difficult to characterize and

easy to overlook), they affect the laser through optical pumping (absorption bleaching), parasitic current leakage, and heat generation.

Figure 29.24 shows the Joule heating distributions caused by the currents supporting stimulated emission of the different modes at $I = 15$ A—as well as how the different vertical modes share/compete for the available gain. These distributions show where the stimulated emission occurs within the device for each of the vertical modes. For the higher order modes, this occurs solely because of the power fed back into

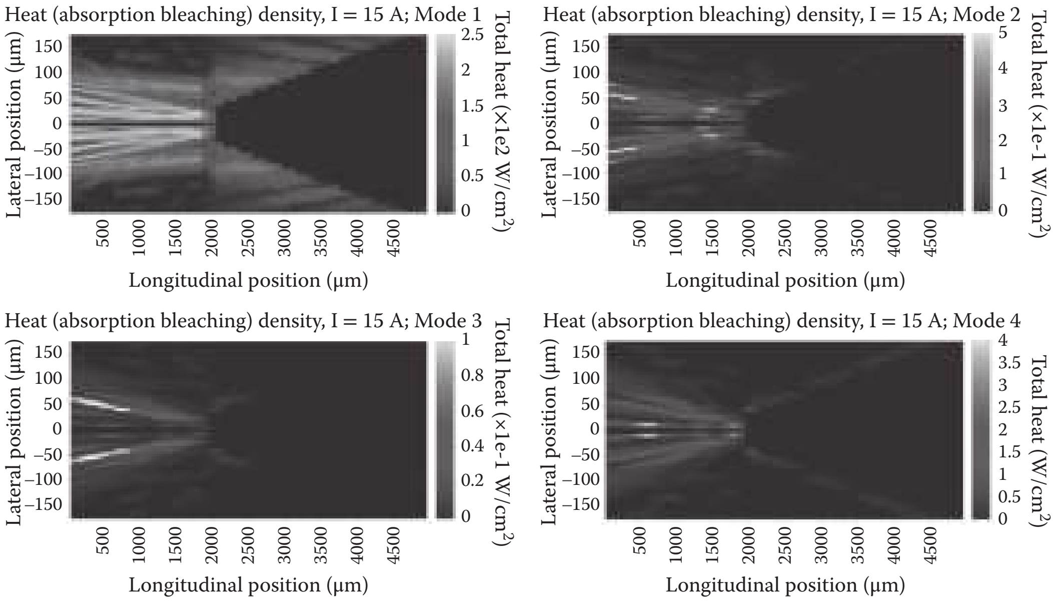

FIGURE 29.25 Self-heating due to optical pumping by each vertical mode at $I = 15$ A.

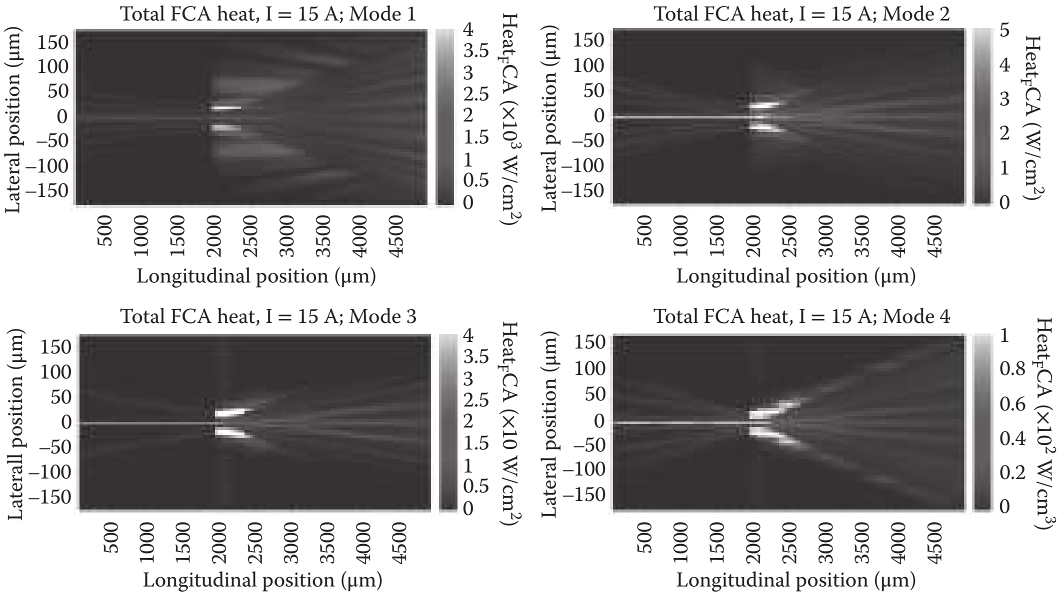

FIGURE 29.26 Self-heating due to free-carrier absorption by each vertical mode at $I = 15$ A.

them from the external cavity. Figure 29.25 shows the self-heating distributions due to optical pumping (absorption) at $I = 15$ A. This pumping causes the absorption bleaching, which plays a critical part in the degradation of the RW spatial filter performance. These distributions show the spatial distribution and relative contributions of the vertical modes to the absorption bleaching. The fundamental mode clearly plays a dominant role in the optical pumping, but the other modes also contribute. Figure 29.26 shows the spatial distributions of self-heating due to FCA. The drop in FCA to the left of the RW–TA interface is due to the RW etch. The higher order modes lose much more power due to FCA than to optical pumping.

TABLE 29.3 Impact of External Cavity Feedback on the Laser Performance (Power, Efficiency, and Beam Quality) for Coupling to All Modes and for Coupling Just to the Fundamental Mode

Simulation	Output Power (W)	PCE (%)	$M^2_{\text{2nd moment}}$
Stand-alone	11.67	47.13	6.32
External cavity (all modes)	9.49	38.39	12.04
External cavity (mode 1 only)	9.46	38.13	12.3

The excited higher order modes clearly play a role in the operation of the device, but their overall power is small compared to that of the fundamental mode (which also has the greatest feedback power). The question is, whether the degradation in PCE and beam quality is primarily controlled by feedback to the higher order vertical modes or to the fundamental mode. Table 29.3 compares the output power, PCE, and $M^2_{\text{2nd moment}}$ for the laser in isolation (SA), with on-axis feedback to all vertical modes and with on-axis feedback to just the fundamental mode. It is clear that the feedback to the fundamental mode has the greatest effect on both PCE and beam quality, while feedback to higher order vertical modes plays a smaller role. This can be understood in the context of an increased output facet reflectivity, which reduces the output power and PCE. At the same time, the optical feedback into the fundamental mode increases the absorption bleaching adjacent to the RW and also the power incident on the DBR reflector inside the RW, as discussed in Section 29.2.2. Both of these effects contribute to the beam quality degradation—the first by reducing the absorption filtering of the diffracted light outside the RW and the second by increasing the power in the side lobes of the diffraction from the DBR reflector.

29.4.2 Parasitic Reflections with Off-Axis Alignment

External feedback couples to the vertical modes differently, when its alignment to the waveguide changes. Here, we explore the impact of a vertical emitter shift of +0.5 μm due to "smile." Table 29.2 shows that modes 2 and 4 have moderate ($\text{MD}_2 = 4.33$) and low ($\text{MD}_4 = 1.90$) values of MD. Figure 29.19 shows they now have large (19%) and moderate (4.8%) coupling coefficients. The performances of these two modes should reveal the relative importance of the MD and the coupling coefficient. The coupling to fundamental mode also decreases from 42.15% (on-axis) to 29.5% (off-axis).

Figure 29.27 shows the power versus current and PCE versus current characteristics of the LOC tapered laser. With the off-axis feedback, the output power and PCE at $I = 15$ A dropped from 11.67 to 9.22 W, while the PCE fell from 47.1% to 37.3%. The coupling into mode 2 increased by a factor of ∼11, allowing both modes 2 and 4 to lase.

Figure 29.28 shows the current dependence of the beam propagation parameter M^2 (both the e^{-2} and second moment definitions) for the off-axis external cavity feedback condition. At $I = 15$ A, the off-axis feedback did not change $M^2_{e^{-2}}$, but $M^2_{\text{2nd moment}}$ increased from 6.32 to 11.72.

29.4.3 Analysis and Discussion

In this section, we analyze and discuss what happens to the power fed back into the higher order modes and how it affects the performance of the laser. We are particularly interested in how the feedback effects depend on parameters that can be influenced during the design of the laser: MD, coupling coefficient, and FCA. We are also interested in how the external cavity optics can be designed to minimize feedback effects.

Tables 29.4 and 29.5 summarize a range of power-related performance metrics for each of the vertical modes at a bias current of 15 A. This bias was selected, as it produces an output power of 11.7 W in the absence of external feedback and is within our desired range of 10–12 W. Table 29.4 is for the on-axis simulation. Table 29.5 is for the off-axis simulation when the emitter is vertically displaced by 0.5μm. Modes in boldface font are lasing. H_{stm} is the Joule heating power of the current needed to support the stimulated

emission of the mode, I_{stm}. H_{abs} is the total heat power due to band-to-band absorption outside the gain regions and is responsible for absorption bleaching. H_{FCA} is the total heat power due to FCA. For the case of on-axis feedback, 91 mW of light is coupled into the higher order modes, which consume 166 mA of current and produce 93 mW of light and 269 mW of heat. For the case of off-axis feedback, 176 mW of light is coupled into the higher order modes, which consume 211 mA of current and produce 94 mW of light and 290 mW of heat.

The previous section showed that external feedback can cause higher order vertical modes to lase. For the laser diode and external cavity simulated here, only the fundamental mode lases without feedback, while mode 4 also lases in the case with on-axis feedback. For the case of off-axis feedback, two higher order vertical modes also lase (modes 2 and 4). The feedback reduces the power and PCE of the fundamental mode, which can be attributed partly to higher order mode lasing and partly to an increase in the effective facet reflectivity by feedback to the fundamental mode. For the device and cavity investigated here, Tables 29.4 and 29.5 suggest that modes with MD of MD < 2 are able to start lasing with comparatively small external cavity coupling coefficients of <5%, while modes with MD ~ 4 require larger coupling coefficients (e.g., 10%–20%). Additional simulations showed that the feedback required for higher order mode lasing also depends on the coupling of the reflected beam into the RW (i.e., into the RW aperture at the RW–TA interface). This is also apparent from the photon distributions in Figure 29.23.

As higher order modes began to lase more strongly, they began to compete with the fundamental mode for the spatial gain distribution and modal power oscillations were observed in the simulations. Although these are not true dynamic simulations, the oscillations have some relation to mode beating and mode partition noise. Despite that the higher order mode powers were small, they appear to affect spatial filamentation and contribute to the near- and far-field patterns of the fundamental mode—consistent with experimental observations (Hempel et al., 2013; Leonhäuser et al., 2014). For stable operation, $M^2_{e^{-2}}$ remains below 1.5 and is insensitive to feedback, while $M^2_{\text{2nd moment}} \sim 6$ for SA operation and nearly doubles with feedback (As discussed in Section 29.4.1, increased feedback to the fundamental mode has the greatest impact on beam quality, but excitation of higher order modes also affects $M^2_{\text{2nd moment}}$). For astable operation (modal power oscillations), there is significant degradation in both $M^2_{e^{-2}}$ and $M^2_{\text{2nd moment}}$.

The optical power back-coupled into the higher order vertical modes also creates heat. This occurs even if the modes are not lasing, but increases dramatically if they are. The heat power of the higher order modes is dominated FCA, followed by Joule heating associated with the current supporting stimulated emission into these modes. The heat generated per feedback photon decreases with MD. This shows the importance of both MD and FCA for suppressing feedback amplification and thus, heating by the higher order modes. At this bias level (15 A), the total heat generation in the higher order modes is 0.269–0.290 W (depending on the alignment of the laser diode), corresponding to a 3.2%–3.6% increase in heat power. The heat generation by the higher order modes alone is responsible for a ~2.3%–2.4% drop in PCE, which increases to ~2.5% if their optical output power is also considered. (This is ~20%–25% of the total drop in PCE.) The heat generated by the excitation of these higher order vertical modes is distributed along the entire cavity—irrespective of the MD. Thus, although the excitation of higher order modes affects the beam quality, it is probably not responsible for observed increases in device degradation. Instead, as shown by Kissel et al. (2016), the observed increase in degradation is probably due to feedback that is *not* coupled into the waveguide (i.e., into the substrate)—particularly when the substrate is strongly absorbing (i.e., $E_{\text{g\_substrate}} < E_{\text{photon}}$).

We have shown that external feedback can cause lasing of higher order vertical modes, resulting in self-heating, mode partition instabilities, and beam quality degradation. The question is *How can we design the laser diode and optical system to reduce the impact of optical feedback?* For the design of the laser diode, MD and FCA are key parameters for suppressing the impact of higher order modes. The external cavity coupling coefficients play a smaller role, but are still important. The stray light from aperture diffraction by the DBR at the back of the RW must be suppressed. For the design of the external cavity, the reflected power must be minimized—for example, by using good AR coatings and, perhaps, tilted facets to eliminate specular reflections. For high powers, however, other approaches may also be required, such as off-axis optical alignment to prevent reflected beams from coupling into the RW filter. Finally, care must also be taken to minimize the power coupled into the substrate—particularly if the substrate is absorbing.

29.5 Conclusions

This chapter discussed how, for many applications that employ high-brightness diode lasers, it is necessary to scale the output power through beam combination techniques, while maintaining an excellent beam quality. All beam combination techniques cause light to be fed back into the laser cavity. In some instances, this feedback can be exploited, such as in the wavelength stabilization of diode lasers and arrays. However, any laser placed in an external system will also suffer from unintentional feedback (parasitic reflections). This chapter describes a detailed method of modeling external cavity lasers with both intentional and unintentional feedback. This model, developed at the University of Nottingham, consists of an advanced laser simulation tool coupled to commercial optical design software.

In large vertical cavity lasers, as required to reach the highest output powers, the vertical cavity must be carefully considered. The structure must be designed to minimize the coupling of parasitic feedback to higher order modes. The effects of parasitic feedback on the performance (output power, PCE, and beam quality) of a tapered laser in a simple optical system are studied. The excitation and propagation of higher order modes increases the FCA causing self-heating, eventually causing degradation of the output power and efficiency. Moreover, the parasitic feedback causes more absorption bleaching, leading also to degradation of the lateral beam quality. Therefore, the inclusion of external parasitic feedback in the design process is highly significant. Coupling coefficients and MD values can be used to engineer a laser structure that is less affected by feedback. This can be accomplished by ensuring that modes with low-to-moderate MD values have the lowest coupling coefficients, thereby minimizing the light coupled into them.

The lateral cavity design also has a significant impact on brightness and the tapered laser is a strong contender for high-brightness laser systems. Tapered lasers offer, to a certain extent, the beam quality advantages of an RW laser and the high power advantages of a BA laser. However, despite this and even without external parasitic feedback, tapered lasers still suffer from beam quality degradation at higher powers. Investigations into the cause of this beam quality degradation reveal that diffraction of light at the back aperture leads to regions adjacent to the RW section becoming bleached from carriers—thereby, degrading the beam quality.

30.1 Introduction

30.1.1 What Is a Single Longitudinal Mode Laser?

Laser is a light source that emits photons described by a "near coherent" optical field. By "coherent optical field," one means the monochromatic electromagnetic field at optical frequency (ω_0) with constant amplitude (A) and phase (θ). Therefore, a coherent optical field can be expressed as $A\cos(\omega_0 t + \theta)$, with phase θ determined by a reference starting time. Any laser built as an oscillator must take spontaneously emitted photons as its initial driven seed, since a laser doesn't have any coherent light as its input. Knowing the fact that the spontaneous emission is a random process, one therefore cannot expect that the laser will give an ideal coherent optical field output. Rather, the laser emits photons described by the ideal coherent optical field, driven by spontaneously emitted photons, for a certain amount of time τ_0 until the emerging of another group of spontaneously emitted photons. Consequently, its output field will experience a sudden change on its amplitude and phase at time τ_0 and this sequence keeps repeating indefinitely. As such, one can express the laser output as a "quasi-monochromatic" electromagnetic field at optical frequency ω_0 as $[A + \delta_a(t)]\cos[\omega_0 t + \theta(t)]$, with $\delta_a(t)$ as a random process with zero mean and $\theta(t)$ also a random process with uniform distribution between 0 and 2π. Once a laser is operated under a bias beyond its threshold, $A >> |\delta_a(t)|$ is satisfied. Hence the only nonideality of a laser output from a coherent optical field lies in its random phase. The difference becomes more apparent if one observes the output optical spectrum of a laser. Actually, as the Fourier transform of an ideal coherent optical field, its frequency-domain spectrum is a delta function that appears at ω_0 with an amplitude of $|A|$. The quasi-monochromatic field, however, has its averaged spectrum in the shape of a "broadened" delta function still peaked at ω_0, but with an amplitude in $\sqrt{1/2\pi}|A|\tau_0$ and a width of $\Delta\omega = 2\pi/\tau_0$. This is because the averaged duration between two consecutive abrupt phase changes is τ_0, which means the quasi-monochromatic field can be described as a series of truncated ideal coherent fields known as a wave train, with τ_0 as the truncation window or the averaged length of the wave train. The Fourier transform of a single truncated coherent field piece corresponds to the convolution between a delta function and a sampling function in the form of $\sin(\omega\tau_0/2)/(\omega\tau_0/2)$ as the Fourier transforms of the ideal coherent field and the flat window function (i.e., 1 for t inside τ_0 and 0 elsewhere), respectively, which gives the result as the aforementioned broadened delta function. Since distinct truncated coherent field pieces in the wave train differ by a time shift only, their Fourier transforms differ just by a phase. Hence, the frequency-domain amplitude spectra of the quasi-monochromatic field as a wave train composed of all these pieces are overlapped as a single peak as shown in Figure 30.1.

It is worth mentioning that the above description is in a "phenomenological" sense, as an accurate treatment of spontaneously emitted photons with a classical electromagnetic field theory is not possible. A physics-based description can be given by exploiting the full quantum mechanics theory, but it will have to involve the quantization of the electromagnetic field and is beyond the scope of this chapter.

The optical frequency ω_0 of the quasi-monochromatic field as the laser output is called the "lasing" frequency. Consequently, the aforementioned spectral peak is called the "lasing" mode or the "longitudinal" mode in order to make a distinction from the "transverse" mode that refers to a spatial field distribution. The term longitudinal comes from the fact that the lasing frequency is determined by the laser resonant cavity. In edge-emitting semiconductor laser diodes, the cavity is set along the longitudinal direction with its geometrical dimension significantly larger than any size in the cross-sectional area. The light is confined inside the cross-sectional area by a waveguide and is only allowed to propagate along the longitudinal direction, or along the cavity. Upon resonance, the lasting longitudinal optical field distribution gives the surviving pattern and determines the lasing frequency. Hence, we have the term longitudinal mode, as opposed to the transverse mode, indicating the confined optical field by the waveguide in the cross-sectional area. Because of the one-to-one correspondence between the optical spectral peak and the lasting longitudinal optical field distribution, conventionally the term longitudinal mode can be referred to either as the spectral peak (or simply as the lasing frequency) or as the spatial field pattern in the cavity

(longitudinal) direction, whereas the term transverse mode can only be referred to as the spatial field pattern in the cross-sectional area, without any spectral meaning.

Generally, a cavity can support multiple resonant patterns and consequently bear with multiple resonant frequencies. Without exception, a laser can also have multiple longitudinal modes, with multiple peaks shown in its output optical spectrum and multiple lasting optical field patterns inside its cavity. With special designs, however, one is able to leave only one surviving longitudinal mode by eliminating all other resonances inside a cavity. A laser with such a cavity is therefore called a single longitudinal mode (SLM) laser.

30.1.2 Why SLM Laser?

When used as the light source in fiber-optic communication systems, a semiconductor laser operated with multiple longitudinal modes suffers the mode partition noise (MPN) [1,2], which stands as the dominant limiting factor to the transmission span of the optical signal in fiber, as the MPN jeopardizes the signal by introducing the intersymbol interference (ISI) among the pulses in the stream—an effect that cannot be simply suppressed through increasing the laser output power. If a multiple longitudinal mode laser is directly modulated, the power allocated to each of its mode fluctuates in a random manner due to the mixed homogeneous and inhomogeneous gain broadening nature of direct bandgapped semiconductors, with the randomness originated from the spontaneous emission noise. Since the signal components carried by different longitudinal modes propagate at different speed due to fiber dispersion, these components won't arrive at the destination at the same time, which results in the pulse spreading over and spilling out of its allocated time slot, and consequently causes ISI. Such ISI bears a random nature due to the random power fluctuation of the multiple longitudinal modes as the signal carriers. Hence, it cannot be eliminated through linear equalization or phase delay compensation. Also, because the random fluctuation is in proportion to the total power, increasing the laser output power won't solve the problem, if doesn't make it worse. Normally, the power penalty soars even starting from a moderate MPN level. For example, at ∼1550 nm (the center of the C-band), the maximum transmission capacity–distance product is only 5 Gbps-km, which means by using a typical multiple longitudinal mode Fabry–Pérot (FP) laser, the 2.5 and 10 Gbps optical signal can only be transmitted for 2 km and 500 m, respectively.

The only viable solution to this problem, therefore, lies in the replacement of the light source with the SLM laser where the MPN naturally disappears.

30.1.3 Current Application Status

Over the past three decades, many SLM laser structures have been proposed and demonstrated; a few dominant structures survived and became popular products on today's market. The super star of the SLM laser is no doubt the distributed feedback (DFB) laser as it takes over 99% shares of the SLM laser market—the throughput of DFB lasers have reached 10 million per year in the recent few years just by one supplier (Wuhan Telecommunication Device Co., Wuhan, China) among the few largest semiconductor laser manufactures.

30.1.4 Why Simple FP Laser Won't Work

It is well known that a piece of straight and smooth optical waveguide with its two mirror-like ends forms a simplest resonant cavity, and semiconductor laser diodes exploiting such a cavity are the FP lasers. A semiconductor optical waveguide, like the typical dielectric waveguide, has the high-pass filter characteristic that cuts off the guiding wave with wavelength longer than some critical value but imposes no constraint on the guiding waves with shorter wavelengths. Although such waveguide does only support discrete space distribution patterns in its cross section and each individual space distribution pattern is also called a transverse mode, one shouldn't mess up it (the transverse mode) with the concept of the longitudinal mode that corresponds a specific field distribution along the cavity and bears a discrete wavelength. Namely, a (dielectric) waveguide picks up the guided transverse mode, but doesn't select a single wavelength from a continuous spectrum of wavelengths that all takes the same transverse mode, except for cutting off the wavelengths below a lower bound. One can also understand it as a given waveguide structure only defines a continuous dispersion relation between the wave propagation constant (β) and the wavelength (λ), which means that, staying with a transverse mode represented by a continuous β–λ curve, one will always manage to find a β indicating a guiding (propagating along the waveguide) wave for a given wavelength λ. Nevertheless, an optical waveguide that only supports a single transverse mode stands as a necessary condition for achieving the SLM operation. As otherwise, each of the multiple nondegenerated transverse modes having its own nonidentical longitudinal mode will have to bear a different wavelength, which makes the SLM operation impossible. We are not going to dig out the waveguide concept further as the focus of this chapter is on the SLM laser. The interested readers can refer to, e.g., References [3,4].

With mirrors on the waveguide ends, the otherwise not interfered forward and backward propagating waves are coupled through the partial reflection. The waves retained inside the waveguide (i.e., the cavity) forms a standing wave pattern that corresponds to a possible longitudinal mode, as the standing wave pattern (other than a homogenous coefficient) doesn't change with time by satisfying the boundary condition at the waveguide ends and consequently bears with a static wavelength. However, in the case where the cavity length (L) is much longer than the wavelength (λ), the boundary condition can be satisfied simultaneously by multiple longitudinal modes. This is because the boundary condition of a simple FP cavity can be equivalent to a round-trip phase condition on aggregate, which reads as follows [5]:

$$2\beta L = 2\pi m \tag{30.1}$$

with m as any integer, $\beta = 2\pi n_{\text{eff}}/\lambda$ denoting the wave propagation constant and n_{eff} the effective index of the waveguide. In Equation 30.1, the facet (end mirror) phase delay has been set to zero as usually the cavity has an effective index higher than that of the surrounding medium, so that the wave experiences the internal (from high refractive index to low refractive index medium) rather than the external (from low refractive index to high refractive index medium) reflection in which the phase delay is indeed zero on reflection. From Equation 30.1, it is apparent that the number of allowed longitudinal modes in an FP cavity is directly proportional to the cavity length scaled by the wavelength, i.e., L/λ. To build an edge-emitting laser with acceptable coherence required by many applications, as well as for obtaining sufficient optical gain for achieving superior laser performance, one has to leave $L \gg \lambda$, hence multiple longitudinal modes exist in such FP cavities.

Other than the aforementioned phase condition, the amplitude condition still needs to be satisfied by the longitudinal mode that survived the phase condition to make it lase. One can therefore consider using the latter mechanism to eliminate the extra longitudinal modes. Unfortunately, the optical gain spectrum of the semiconductor material is much broader (~60 nm) than the FP longitudinal mode spacing that can readily be derived from Equation 30.1 as follows [5]:

$$\Delta\lambda = \frac{\lambda_0^2}{2n_g L} \tag{30.2}$$

with λ_0 as the center wavelength and $n_g = n_{\text{eff}} + (dn_{\text{eff}}/d\lambda)\lambda_0$ denoting the group index. For example, for typical InGaAsP/InP or AlGaInAs/InP semiconductor laser diodes, $n_g \sim 3.4$, their mode spacing vary from 0.6 to 1.2 nm in the O-band ($\lambda_0 \sim 1300$ nm), and from 0.9 to 1.8 nm in the C-band ($\lambda_0 \sim 1550$ nm), respectively, when the cavity length changes from 400 to 200 μm. As such, multiple longitudinal modes with their wavelengths closely packed adjacent to the material gain peak will share almost the same gain. Since the partially inhomogeneous gain in a semiconductor material cannot be fully clamped, small gain differences among these longitudinal modes won't be sufficient to effectively suppress the side modes, which eventually excites multiple longitudinal lasing modes. This is the main reason that the material gain dispersion in general cannot be used for longitudinal mode selection, not to mention that in the case of direct modulation, any dynamic gain change will disrupt the gain profile and consequently jeopardize any attempt of using the gain to discriminate longitudinal modes.

One therefore understands why conventional semiconductor FP laser diodes operate in multiple longitudinal modes. Above analysis also shed some light on the direction one needs to follow in the effort of developing SLM lasers, i.e., the simple FP cavity needs to be replaced by more complicated ones or modified with added structures with further built-in wavelength selectivity.

30.1.5 Classification of SLM Lasers

Canonically, there are three main approaches for semiconductor laser diodes to achieve SLM operation, all by introducing wavelength-selective cavities. These three categories of SLM lasers can be classified as the grating-assisted lasers that exploit the grating in their cavities, the coupled-cavity lasers that have extra optical (band-pass) filters in their cavities, and the external cavity lasers that use either one of the above-mentioned configurations, or the injection locking mechanism to purify the lasing spectrum but by placing the extra components outside of the main FP cavity through hybrid packaging. Theoretically, lasers in the latter category makes no difference from their counterparts in the first two categories, other than some quantitative difference on the coupling strength between the main FP cavity and the added wavelength selection components. Since they never become the mainstream product except in a few specific applications where the cost is not a concern, SLM lasers in this category are not discussed. The interested readers can refer to, e.g., References [6–8].

30.1.6 Organization of this Chapter

Sections 30.2 and 30.3 will be dedicated to discuss the grating-assisted lasers and the coupled-cavity lasers, respectively, covering their structures and working mechanisms, governing equations describing the device physics processes, and numerical simulation results on device performance.

The following section briefly describes the recent development on this topic, by showing a few advanced structures for emerging demands, their operating principles, the measured prototype device performance, in contrast to numerical simulation results.

30.2 Grating-Assisted SLM Laser Diodes

30.2.1 Grating Analysis

Noticing that a normal facet mirror formed by a dielectric (semiconductor)—dielectric (air) interface doesn't have wavelength dependence, which makes the FP cavity formed by a straight and smooth waveguide with such facet mirrors on both ends lacking the ability to select a single lasing wavelength, one would naturally think of exploiting a wavelength-selective reflector to replace the end facet mirror, which directly leads to the birth of distributed Bragg reflector (DBR) laser. This idea can logically be extended to turn the entire or part of the original straight and smooth waveguide inside the cavity into a corrugated waveguide (i.e., the waveguide grating) for lasing wavelength selection, which leads to the innovation of a whole family of DFB lasers, although the original idea of the DFB laser was independently proposed [9]. In all such grating-assisted SLM lasers, the grating obviously plays a center role. We therefore start this section by analyzing the grating itself.

A uniform (passive) grating with period Λ in any shape can be viewed as a linear superposition of many sinusoidal gratings with harmonic periods Λ/m, $m = 1, 2, 3, \ldots$, according to the Fourier expansion, simply because the refractive index change along the grating follows a periodic function. A phase-matching condition can therefore be found as follows [10]:

$$k_i \cos\theta_i = \pm\frac{2\pi}{(\Lambda/m)} + k_{om}\cos\theta_{om} \tag{30.3}$$

with k_i and k_{om} indicating the incident and mth order diffracted (by the mth order sinusoidal grating) wave numbers, respectively, θ_i and θ_{om} the incident and mth order diffracted wave angles as shown in Figure 30.2, respectively.

In this application, the incident light is propagating along the laser waveguide, $\theta_i = 0$ and $k_i = \beta = 2\pi n_{\mathrm{eff}}/\lambda$. What one wants is to have the incident wave turn around by 180°, propagating along the waveguide in the opposite direction, which requires $\theta_{om} = \pi$ and $k_{om} = \beta = 2\pi n_{\mathrm{eff}}/\lambda$, hence one has, from Equation 30.3,

$$2\beta = \frac{4\pi n_{\mathrm{eff}}}{\lambda} = \frac{2\pi m}{\Lambda}, \text{ or } \Lambda = \frac{m\lambda}{2n_{\mathrm{eff}}} \tag{30.4}$$

as the rule to select the grating period for coupling the forward and backward propagating waves in the waveguide at a given wavelength (λ), with n_{eff} still indicating the effective index of the waveguide. The wavelength that satisfies condition (Equation 30.4) is conventionally called Bragg wavelength. It is self-evident that for a given grating with fixed Λ, any wavelength deviated from λ wouldn't satisfy the phase-matching condition (Equation 30.4), consequently at such wavelength there won't be any coupling between the forward and backward propagating waves. As such, an ideal grating (with infinite length) would indeed select a single wavelength to reflect, which makes a perfect mirror as required by an SLM laser cavity. In reality, the grating cannot be made infinitely long. One would therefore expect some residue reflection at deviated wavelengths. Nevertheless, by making the grating sufficiently long, one can always expect a mirror with sufficient wavelength selection required by the SLM operation.

Yet another design consideration is how to choose the grating order. By choosing a sinusoidal grating component with order $m = M$ to be satisfied by Equation 30.4, one understands that those sinusoidal grating components with orders beyond M won't take any effect, simply because if $\lambda = 2n_{\mathrm{eff}}\Lambda/M$, for any grating orders in $M + n$, $n = 1, 2, 3, \ldots$, their diffraction angles according to Equation 30.4,

$$\theta_{o(M+n)} = \arccos\left(1 + \frac{2n}{M}\right) \tag{30.5}$$

offer no real solution at all. Physically, the distance between the two consecutive reflections of the grating in order $M + n$ is $\Lambda/(M + n)$ shorter than half of the equivalent wavelength in waveguide $\lambda/(2n_{\mathrm{eff}}) = \Lambda/M$, therefore, constructive addition of the waves on its reflection is impossible because there is no phase-matching condition (i.e., two identical phases) that can possibly be found within 2π. This can be seen more clearly if we show the round-trip phase delay between the two consecutive reflections explicitly by

$$2\frac{2\pi n_{\mathrm{eff}}[\Lambda/(M+n)]}{\lambda} = 2\frac{2\pi n_{\mathrm{eff}}[\Lambda/(M+n)]}{2n_{\mathrm{eff}}\Lambda/M} = 2\pi\frac{M}{M+n} < 2\pi.$$

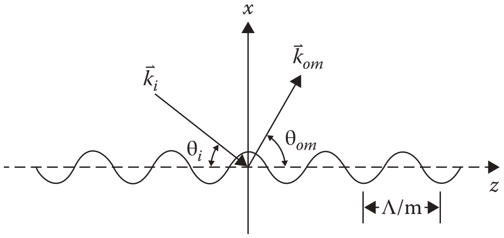

FIGURE 30.2 An illustrative diagram showing the light diffraction by a grating, with Λ/m indicating the mth order harmonic period, θ_i and θ_{om} the incident and mth order diffracted wave angles in respect to the grating plane, respectively, $\vec{k}_i$ and $\vec{k}_{om}$ the incident and mth order diffracted wave vectors, respectively; they must be in the same plane as required by the matching tangential field condition at the grating boundary.

Therefore, those sinusoidal grating components with orders higher than M virtually take no effect, because all the reflected waves by these higher order grating components cannot be added in a constructive way, rather, they all tend to be cancelled out.

For sinusoidal grating components with orders $n = 1, 2, \ldots, M - 1$, they will make the incident wave diffract into different directions, with their angles specified, according to Equation 30.4:

$$\theta_{on} = \arccos\left(1 - \frac{2n}{M}\right) \tag{30.6}$$

For example, if one chose the Bragg wavelength to match the second-order sinusoidal grating component $M = 2$ and $\lambda = n_{\text{eff}}\Lambda$. The second-order sinusoidal grating component therefore couples the forward going wave in the waveguide into the backward going wave, which offers the effect one needs, whereas the first-order sinusoidal grating component couples the forward going wave in the waveguide into a wave going along the vertical direction ($\theta_{o1} = 90°$). The latter appears to be a vertically radiating wave that leaves away from the waveguide. The rest sinusoidal components with their orders higher than 2 all take negligible effect.

In this specific application, one usually doesn't want to create any accompanying radiation that will likely bring in unwanted loss, hence one should align the Bragg wavelength with the first-order sinusoidal grating component $M = 1$ and $\lambda = 2n_{\text{eff}}\Lambda$. As such, the forward and backward waves are coupled at the lowest grating order and consequently it leaves no lower order grating components for the guided waves to be coupled to the radiating wave. Again, those higher order grating components ($M > 1$) virtually bring in no effect.

From the above qualitative analysis, one also knows that it is the period, rather than the shape, that dominates the grating characteristics. And the above analysis is valid under the assumption that the grating is sufficiently long. The required grating length to achieve certain performance, however, can only be evaluated in connection with the grating coupling strength in unit length through numerical approach. Also known as the grating coupling coefficient (κ), the unit length grating coupling strength is determined by the grating shape and the refractive index contrast, or the effective index contrast (Δn_{eff}) on aggregate. In the most general case, one needs to use the mode-matching method (MMM) [11,12] to calculate the reflection, transmission, and loss spectra of a given waveguide grating. A good approximation is to chop the waveguide grating into many short pieces along the guiding direction. By solving the mode in each piece as an eigenvalue problem defined in the local waveguide cross section, one will be able to extract the effective index in each piece as the eigenvalue solution. One can therefore use the one-dimensional (along the guiding direction) transfer matrix method (TMM) [13,14] to solve for the aforementioned grating spectra.

While numerical approaches would offer us an accurate result, one sees little physics and it is also hard to link the grating design parameters to its characteristics. For this reason, one usually uses the full numerical solver as a simulation tool only to validate or confirm a design. One therefore still needs an analytical or semi-analytical tool for the grating design purpose. For this reason, we will show following the expressions [15]. Actually, the refractive index distribution of a waveguide grating can be written in the Fourier series:

$$n^2(x, y, z) = n_0^2(x, y) + \sum_{m \neq 0} \Delta n_m^2(x, y) e^{jm\frac{2\pi z}{\Lambda}} \tag{30.7}$$

due to its periodicity along z (the guiding direction), where n_0^2 and Δn_m^2 indicate the DC and mth order coefficient of the square refractive index in the expansion, respectively, and can readily be found by taking the overlap integral (along z within one period Λ) between the square refractive index (n^2) and the respective sinusoidal grating order (in its complex form $e^{jm2\pi z/\Lambda}$, $m = 0, \pm 1, \pm 2, \ldots$) normalized by the period Λ. The cross-sectional (x, y) dependence of the refractive index reflects the waveguide structure. Consequently, the coupling coefficient of the m^{th} order sinusoidal grating component can be found by

$$\kappa_m = \frac{\pi}{\lambda n_{\text{eff}}} \frac{\iint\limits_{\Sigma} \Delta n_m^2(x, y)|\varphi(x, y)|^2 dxdy}{\iint\limits_{\Sigma} |\varphi(x, y)|^2 dxdy} \tag{30.8}$$

where n_{eff} and $\varphi(x, y)$ denote the effective index and optical field distribution of the waveguide defined by the background refractive index distribution (i.e., the DC component in the Fourier expansion) $n_0^2(x, y)$, respectively, and can be found by solving the following eigenvalue problem (with n_{eff} and φ taken as the eigenvalue and eigenfunction, respectively):

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)\varphi(x, y) + \left(\frac{2\pi}{\lambda}\right)^2 [n_0^2(x, y) - n_{\text{eff}}^2]\varphi(x, y) = 0 \tag{30.9}$$

In Equation 30.8, the integration area Σ extends to where φ can reach. In following discussions, we will stay with the first-order Bragg grating unless otherwise specified. Hence we will use $\kappa_\pm$ to indicate $\kappa_M = \kappa_{\pm 1}$. One also needs to note that Equation 30.7 is only valid for an infinitely long grating, consequently the grating coupling coefficient ($\kappa_\pm$) given in Equation 30.8 is subject to the same assumption. Practically for $n_{\text{eff}}L/\lambda > 500$, such extracted $\kappa_\pm$ in conjunction with the analytical spectrum expression (shown below) provides no appreciable difference from the accurate result obtained by the full numerical approaches (e.g., MMM or TMM).

For a fully confined guided mode (hence φ is real), both the grating symmetry and the nature of the complex material refractive index change dictate the coupling complexity. For a purely refractive index-coupled grating with real $n^2 - n_0^2$, one may easily find from Equation 30.7 that $\Delta n_{-1}^2 = (\Delta n_{+1}^2)^*$, hence $\kappa_- = \kappa_+^*$ according to Equation 30.8. One may conclude that, if the grating has a center symmetry, n^2 is an even function of z and $\Delta n_{\pm 1}^2$ are real, $\kappa_\pm$ are real and $\kappa_- = \kappa_+$, whereas if the grating has a center antisymmetry, n^2 is an odd function of z and $\Delta n_{\pm 1}^2$ are imaginary, $\kappa_\pm$ are imaginary and $\kappa_- = -\kappa_+$. For a purely gain- or loss-coupled grating with imaginary $n^2 - n_0^2$, one finds, however, $\Delta n_{-1}^2 = -(\Delta n_{+1}^2)^*$ from Equation 30.7, hence $\kappa_- = -\kappa_+^*$ following Equation 30.8. One therefore knows that, if the grating has a center symmetry, n^2 is an even function of z and $\Delta n_{\pm 1}^2$ are imaginary, $\kappa_\pm$ are imaginary and $\kappa_- = \kappa_+$, whereas if the grating has a center antisymmetry, n^2 is an odd function of z and $\Delta n_{\pm 1}^2$ are real, $\kappa_\pm$ are real and $\kappa_- = -\kappa_+$. Generally, for a complex-coupled grating with complex $n^2 - n_0^2$, or for a grating structure that is neither symmetric nor antisymmetric, $\Delta n_{\pm 1}^2$ are complex so are $\kappa_\pm$.

For a waveguide grating with a length of L without any extra end facet reflection [which can practically be realized by, e.g., antireflection (AR) coating on the end facet], one finds the amplitude reflection spectrum (defined as the ratio of the backward and forward going guided wave at the input port) and the amplitude transmission spectrum (defined as the ratio of the forward going guided wave at the output and input port) as [16]:

$$R_{DBR}^{\pm}(\lambda) = \frac{j\kappa_\mp \sinh(\gamma L)}{\gamma \cosh(\gamma L) - (\alpha + j\delta)\sinh(\gamma L)} \tag{30.10}$$

$$T_{DBR}^{\pm}(\lambda) = \frac{\gamma}{\gamma \cosh(\gamma L) - (\alpha + j\delta)\sinh(\gamma L)} \tag{30.11}$$

where $\gamma^2 = (\alpha + j\delta)^2 + \kappa_+\kappa_-$ and $\delta = 2\pi[n_{\text{eff}}/\lambda - 1/(2\Lambda)]$, with λ now indicating the wavelength variable and α the amplitude modal loss (< 0) or gain (> 0) variable of the waveguide grating. Figure 30.3

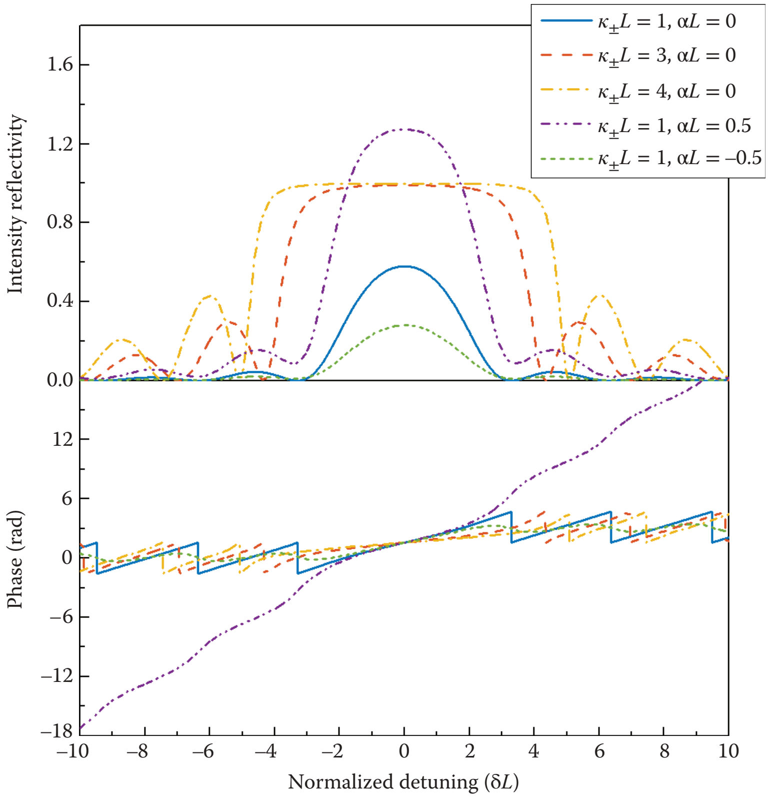

FIGURE 30.3 Reflection spectra of the Bragg grating under different normalized coupling coefficients $\kappa_{\pm}L = 1, 3, 4$ without gain or loss $\alpha L = 0$, and under $\kappa_{\pm}L = 1$ with gain $\alpha L = 0.5$ and loss $\alpha L = -0.5$.

shows respectively the amplitude and phase of the reflection spectrum of a purely refractive index-coupled grating, under different normalized (real) grating coupling coefficient ($\kappa_{\pm}L$) and normalized modal loss/gain (αL).

As can be seen from the spectrum, the maximum reflection happens at the Bragg wavelength. A Bragg stop-band can be identified by the main lobe with its width defined as the difference between the two zero-reflection wavelengths. Zero-reflection happens to the wave at the wavelength with its reflections from two adjacent grating teeth completely canceled out due to a phase delay of π, which makes the further cancel out of all reflections through the entire grating due to the equal tooth distance (i.e., the grating period Λ). Obviously, the wave at the zero-reflection wavelength will pass through the grating with 100% transmissivity as if the waveguide grating offers nothing more than a phase delay unit. For a purely passive, refractive index-coupled grating ($\kappa_+\kappa_- = \kappa_+\kappa_+^*$, hence $\kappa_+\kappa_-$ is real and can be written as $|\kappa|^2$) without any modal gain or loss ($\alpha = 0$), zero-reflections (maximum transmission) happen at $\gamma L = jk\pi$, $k = \pm 1, \pm 2, \pm 3, \ldots$, or $\delta L = \pm\sqrt{(|\kappa_+|L)^2 + (k\pi)^2}$. The Bragg stop-band width is therefore given by [16]

$$2\delta L = 2\sqrt{(|\kappa|L)^2 + \pi^2} \text{ or } \Delta\lambda_B = \frac{\lambda_B^2}{n_{\text{eff}}L}\sqrt{(|\kappa|L/\pi)^2 + 1} \tag{30.12}$$

with $\lambda_B = 2n_{\text{eff}}\Lambda$ indicating the Bragg wavelength (center of the Bragg stop-band) given by the phase-matching condition (Equation 30.4) for the first-order Bragg grating. It is apparent that the Bragg stop-band width ($\Delta\lambda_B$) increases with the normalized coupling coefficient almost linearly if $|\kappa|L >> \pi$, or quadratically if $|\kappa|L << \pi$. It is worth mentioning that the measured stop-band width of the lasing spectrum in the DFB lasers is always smaller than the Bragg stop-band width, and the former approaches $\Delta\lambda_B$ as $|\kappa|L$ increases. We explain the underlying physics later in discussion of DFB lasers.

In the near infrared fiber-optic communication wavelength range, the first-order Bragg grating has its period in the submicrometer range (e.g., ~200 nm in the O-band centralized at 1300 nm and ~240 nm in the C-band centralized at 1550 nm). It is impossible to fabricate the waveguide surface-relief grating by the standard photolithography technique. Rather, one has to exploit more complicated technologies such as the holographic lithography [17] or the electron-beam lithography (EBL) [18]. While the former doesn't need expensive facility and fits the mass production mode, it can hardly create any nonuniform grating pattern. The latter, conversely, can create arbitrary user-defined grating pattern but needs expensive machine and doesn't fit the production mode for the long hours it needs to scan-write the whole wafer. A newly emerged technique, nano-imprinting [19], seems to be very promising as the ultimate solution to the fabrication of the waveguide grating. With the imprinting mask written by EBL with complicated patterns, one can use the mask repeatedly to transfer its pattern onto wafers by a pressing-and-developing process through the spin-coated pressure-sensitive deforming-resister on the wafer surface. As such, the expensive EBL writing just needs to be done once on the mask, the later pattern transfer process from the mask to wafers (imprinting) is fast and reliable, with an even better quality compared to the widely used holographic lithography technique [20]. It is also worth mentioning that the invention of the "floating" grating idea [21] solves the problem in the precise control of the grating coupling strength and guarantees its repeatability in the mass production mode, as the depth of the grating teeth is now determined by the grating layer thickness which can be made accurate (to sub-10 nm range) in material growth, as opposed to be given by the etching depth which is not only hard to control down to 10~20 nm but also hardly repeatable. This invention sets a milestone on the mass production as well as the cost reduction of DFB lasers.

30.2.2 Distributed Bragg Reflector Laser

A typical DBR laser has a structure shown in Figure 30.4. With the first-order Bragg grating placed on one or both ends of an FP laser as the reflector, the coupling between the forward and backward going waves inside the cavity becomes wavelength dependent.

Similar to the lasing condition derived for the FP laser [5], one can readily find the resonance condition for the DBR laser by following an approach of matching the traveling wave with itself after a

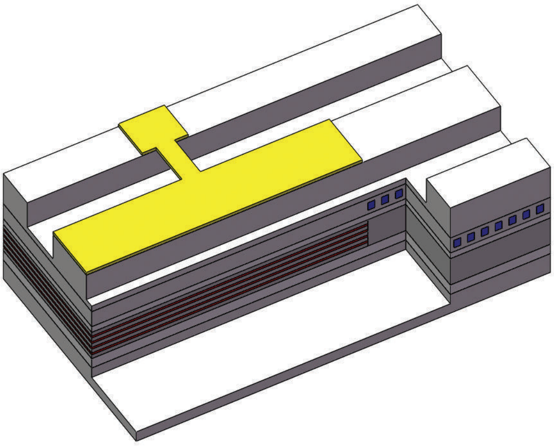

FIGURE 30.4 The DBR laser structure.

round trip inside the cavity:

$$R_l(\lambda)R_r(\lambda)e^{2[g-\alpha_i+j\frac{2\pi n_{\text{eff}}}{\lambda}]L_{ar}} = 1 \tag{30.13}$$

with R_l and R_r denoting the wavelength-dependent amplitude reflectivity of the Bragg grating reflector on the left and right end of the active region, respectively, given in the form of (Equation 30.10), g the modal gain, α_i the modal internal loss, and L_ar the active region length. One can further split the lasing condition (Equation 30.13) into the amplitude and phase condition as

$$g = g_{th} \equiv \alpha_\text{i} + \alpha_\text{c} \equiv \alpha_i + \frac{1}{2L_\text{ar}} \ln \frac{1}{|R_l(\lambda)||R_r(\lambda)|} \tag{30.14}$$

and

$$\frac{4\pi n_{\text{eff}} L_{ar}}{\lambda} + \phi_l(\lambda) + \phi_r(\lambda) = 2\pi m,\ \ m = 1, 2, 3, \ldots \tag{30.15}$$

where ϕ_l and ϕ_r indicate the phase of the amplitude reflectivity of the Bragg grating on the left and right end, respectively. It is clear that, following Equation 30.14, only the wave at the Bragg wavelength sees the highest reflection and consequently has the smallest cavity loss defined by $\alpha_\text{c} \equiv -(0.5/L_\text{ar})\ln(|R_\text{l}||R_\text{r}|)$, since at least one of the end reflectors will offer the highest reflection (i.e., either R_l, or R_r, or both will take the largest value) at the Bragg wavelength following the grating reflection spectrum shown in Figure 30.3. It then requires the smallest modal gain to reach the threshold in the neighborhood of the Bragg wavelength. It is not as clear though, following Equation 30.15, that one can find a solution to λ in the neighborhood of the Bragg wavelength, not going beyond $\lambda_B^2/(2n_\text{eff}L_\text{ar})$, with λ_B indicating the Bragg wavelength ($2n_\text{eff}\Lambda$). Actually, if one takes $\lambda = \lambda_\text{B} + \Delta\lambda$ ($\Delta\lambda \sim \lambda_\text{B}^2/(2n_\text{eff}L_\text{ar}) << \lambda_\text{B}$) in Equation 30.15 to obtain

$$2\pi\Delta\lambda\left(\frac{2n_\text{eff}L_\text{ar}}{\lambda_\text{B}^2}\right) = \frac{4\pi n_\text{eff}L_\text{ar}}{\lambda_\text{B}} + \phi_l(\lambda) + \phi_r(\lambda) - 2\pi m \tag{30.16}$$

and also to notice that the total phase on the right hand side of Equation 30.16 is a slow-varying function of λ in the neighborhood of λ_B following Figure 30.3, one immediately finds that as $\Delta\lambda$ changes from 0 to $\lambda_\text{B}^2/(2n_\text{eff}L_\text{ar})$, the total phase on the left-hand side of Equation 30.16 sweeps over an entire range of 2π, which means that the phase on the two sides of Equation 30.16 will have a matching point within the interval between λ_B and $\lambda_B \pm \lambda_B^2/(2n_\text{eff}L_{ar})$, given the fact that the phase takes 2π as its modulo. One therefore reaches the conclusion that the phase condition (Equation 30.15) always has a solution in a close neighborhood of the Bragg wavelength bound by $\lambda_\text{B}^2/(2n_\text{eff}L_\text{ar})$. Consequently, one knows that the amplitude condition (Equation 30.14) and the phase condition (Equation 30.15) jointly select a single lasing wavelength near the Bragg stop-band center of the end grating reflector. This explains why the DBR laser operates under the SLM.

The main advantage of the DBR laser lies in the separation of its gain and wavelength selection (i.e., the passive Bragg grating) region. Since the grating region is not biased, the wavelength selection mechanism suffers little change with the injection current in the gain region. One then expects a stable SLM operation with high side-mode-suppression-ratio (SMSR) and small wavelength chirp, which is evidenced by many publications [22,23]. It is also quite convenient to introduce a lasing wavelength tuning in DBR laser, as one can readily bias the grating region by a separate electrode from the gain region. As such, the current injection in the grating region introduces an effective index change, since the carrier-induced gain/loss change will have an accompany refractive index change following the Kramers–Kronig relation. Therefore, the peak reflection wavelength (the Bragg wavelength) given by Equation 30.4 will change with the current injected in the grating region, which causes the lasing wavelength change accordingly. Usually, a phase adjustment section needs to be inserted between the gain and the grating region to separately tune the phase for matching the lasing condition, as otherwise the DBR laser may cease lasing or experience a lasing mode hopping due to the mismatch of the phase condition. However, since the grating region has to be made transparent to the lasing wavelength, as otherwise the light will be absorbed by the unbiased passive grating region if it has the same band-gap with the active region, the fabrication of DBR lasers inevitably involves the monolithic integration technique that still stands as an unsolved problem up to today, for its low yield. With the birth of silicon photonics in the recent decade, it is quite promising to make the Si photonics DBR laser by bonding a direct band-gaped III-V compound semiconductor gain block on top of the silicon-on-insulator (SOI) waveguide, with the Bragg grating engraved on SOI. There is a hope that the DBR laser will be reborn with the booming Si photonics.

30.2.3 Distributed Feedback Lasers

A typical pure refractive index-coupled uniform-grating DFB laser has a structure shown in Figure 30.5. Unlike the DBR laser with a gain region made of smooth waveguide separated from the passive grating region, the DFB laser has these two regions merged into one, which makes the laser cavity substantially different from the aforementioned FP or DBR structures in the sense that the forward and backward going waves are constantly coupled in a distributive manner inside the cavity rather than in a lumped sum manner at the two ends of the cavity only. A wavelength discrimination mechanism is therefore brought in by such distributed coupling, since only the waves at the phase matched wavelength(s) will possibly add constructively to establish a standing wave pattern (i.e., a longitudinal mode) inside the cavity, which imposes a stringent condition that may likely purifies the lasing spectrum by cutting off most of the cavity modes otherwise allowed in the FP cavity.

An immediate finding is that this structure won't have its lasing wavelength at the Bragg wavelength anymore. This is because the wave near the Bragg wavelength sees the highest reflection. It therefore cannot travel far along the waveguide grating that also provides the gain. Consequently, it cannot obtain sufficient gain as required for the lasing to happen. On the contrary, at the Bragg stop band edge where the grating offers zero-reflection as shown in Figure 30.3, a maximum transmission through the grating region is obtained. Although the wave at this particular wavelength experiences the highest single-pass gain as it sees the entire length of the grating (with gain), it cannot be the lasing mode either since no reflection happens to it so that no resonance can be established. In this sense, the lasing should happen somewhere in between, i.e., the traveling waves at the lasing wavelength should be partially reflected by the grating to

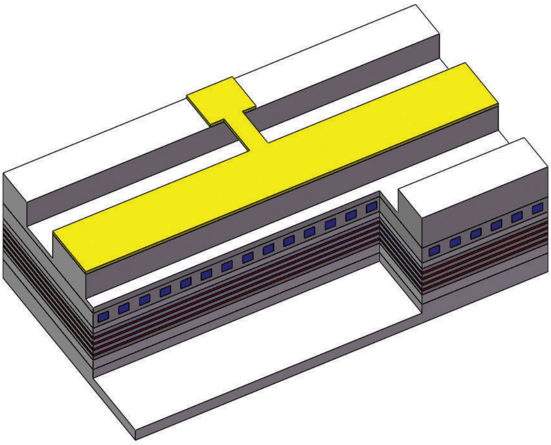

FIGURE 30.5 The DFB laser structure.

establish the resonance. It should be partially transmitted in order to experience the gain in the grating region as well. As such, the phase matching and amplitude sustenance (gain) conditions must be mixed.

Following the same thought, i.e., searching for the consistent condition between the wave and itself after a round trip inside the cavity, one can still obtain the resonance condition for the DFB cavity [24], which will stand as the lasing condition of the DFB laser. In the general case, however, one cannot expect to have analytical expressions for such lasing condition, so that we will cover the general case by the full numerical model introduced later. To gain an insight into the DFB laser, we will analyze a simple case with both of the end facet reflections and longitudinal spatial horn burning (LSHB) effect neglected. Actually, the lasing condition of such a simple DFB laser can be found by setting the denominator of Equation 30.10 and/or Equation 30.11 equal to zero. The associated infinite reflection and transmission indicate that the device can offer output without input—a feature must be carried by an oscillator. Hence one has

$$\gamma \coth(\gamma L) = \alpha + j\delta, \ \gamma^2 = (\alpha + j\delta)^2 + \kappa_+\kappa_- \tag{30.17}$$

Usually, for a given $\kappa_\pm L$ as the grating design parameter, one solves for γL from

$$(\gamma L)^2 \coth^2(\gamma L) = (\gamma L)^2 - \kappa_+\kappa_- L^2 \tag{30.18}$$

which has the same solution set as Equation 30.17. Hence the normalized gain (αL) and detuning (δL) can be found by

$$\alpha L + j\delta L = \pm\sqrt{(\gamma L)^2 - \kappa_+\kappa_- L^2} \tag{30.19}$$

from which one will be able to obtain the lasing modal threshold gain (from $g_{\text{th}} \equiv \alpha_{\text{i}} + \alpha$, α_i the modal internal loss) and the lasing wavelength (by solving $\delta = 2\pi[n_{\text{eff}}/\lambda - 1/(2\Lambda)]$ for λ). The normalized gain (αL) and detuning (δL) for different normalized grating coupling coefficient ($\kappa_\pm L$) are plotted in Figure 30.6, as the solution to Equations 30.18 and 30.19 obtained by a numerical root searching program built on Muller's algorithm [25].

The threshold gain solution indicates that, in a similar role as $\alpha_c = -(0.5/L)\ln(|R_{\text{l}}||R_{\text{r}}|)$ to the FP or DBR cavity, α, as the cavity loss to the DFB cavity, is in proportion to $1/(\kappa L)$. For a DFB grating design

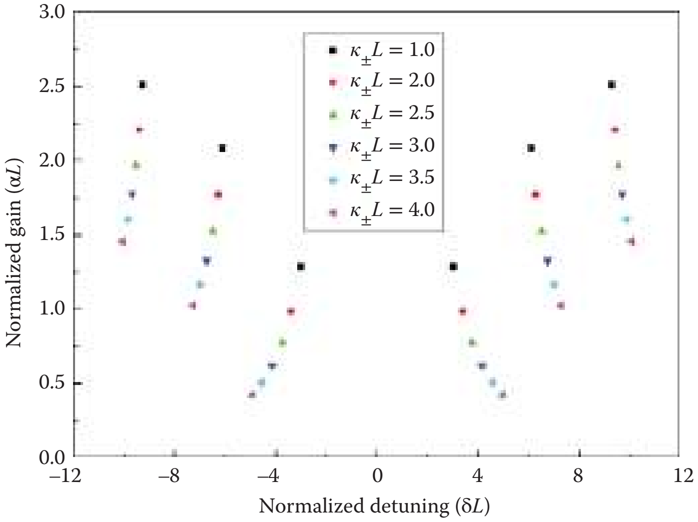

FIGURE 30.6 $\alpha L \sim \delta L$ for different $\kappa_\pm L$ as solutions to Equations 30.18 and 30.19.

with a higher $\kappa_{\pm}$, the cavity is more closed as an FP or DBR cavity with a higher end reflection R, and with the cavity length scaled in the same way. This conclusion, together with the above discussion on its lasing wavelength position, stands as the most basic design guidance for the DFB laser. Also for the DFB laser with high $\kappa_{\pm}L$ design, its cavity loss reduces so as the required modal gain to reach the lasing threshold, the lasing wavelength will therefore approach more closely to the zero-reflection wavelengths, as the wave may have sufficient gain to reach its threshold through fewer passes, and consequently less reflection is necessary. Namely, as the threshold gain approaches to zero, the lasing will happen near the Bragg stop-band edge. Hence one finds that the lasing wavelength of the DFB laser with higher $\kappa_{\pm}L$ should be closer to the zero-reflection wavelength of the unbiased grating, i.e., the Bragg stop-band edge.

A serious issue with the purely refractive index-coupled uniform-grating DFB laser is, however, its dual-mode operation nature originated from the double degeneracy caused by the center mirror-symmetry (or antisymmetry) of the cavity. It is quite obvious that, from Equation 30.18, for any real $\kappa_{+}\kappa_{-}$, once γ is a solution, $-\gamma$ and $\pm\gamma^{*}$ are all solutions. Hence for any solution set (α, δ), $(\pm\alpha, \pm\delta)$ are all possible solutions according to Equation 30.19, which means that for any modal gain required to reach the lasing threshold, also known as the DFB laser cavity loss (α as a solution to the lasing condition), there is a double degeneracy of the lasing wavelength corresponding to $\pm\delta$, respectively. These two lasing wavelengths sit on each side of the Bragg wavelength, and approach to the Bragg stop-band edges as $\kappa_{\pm}L$ increases, in consistency with previous analysis. Physically, this effect can be explained by the two equally possible standing wave patterns shown in Figure 30.7a. In a DFB laser cavity with the center mirror-symmetry ($L/\Lambda = n + 1/2$, n is an integer) or center mirror-antisymmetry ($L/\Lambda = n$ is an integer) and with zero end facet reflections (the latter condition can actually be further relaxed to identical end facet reflections), there exist two possible standing wave patterns as a result of the constructive addition of the distributively coupled forward and backward going waves. They share the same gain inside the cavity and have the identical cavity loss. The only difference between the two patterns is that one of them has its intensity peak aligned with the high refractive index region in every period, whereas the other one has its intensity peak aligned with the low refractive index region in every period. As such, the former and latter pattern will see the cavity mainly in high and low refractive index, respectively. Consequently, the former and latter will take the longer (red) and shorter (blue) lasing wavelength, respectively, on each side of the center Bragg wavelength. The double degenerated longitudinal mode with different standing wave pattern at different lasing wavelength but with

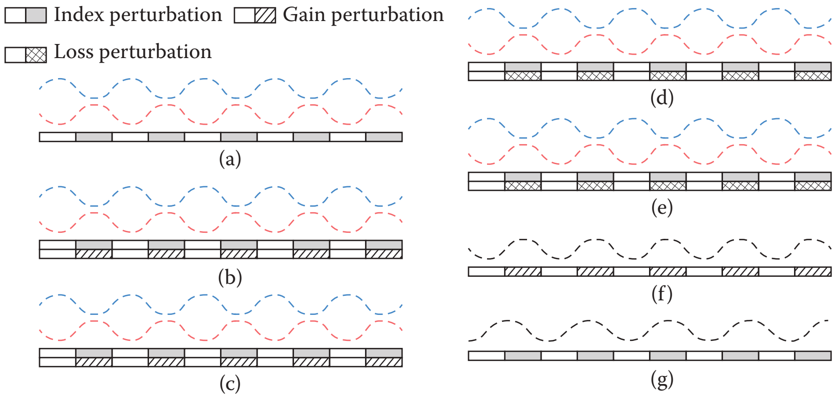

FIGURE 30.7 Schematic diagrams for (a) purely refractive index-coupled uniform-grating DFB, (b) partially gain-coupled in-phase DFB, (c) partially gain-coupled antiphase DFB, (d) partially loss-coupled in-phase DFB, (e) partially loss-coupled antiphase-grating DFB, (f) purely gain-coupled DFB, (g) quarter-wavelength phase-shifted (QWPS) DFB; the blue and red dashed lines in (a)–(e) show the intensity standing wave patterns of the longitudinal modes bearing the short and long wavelength (on the blue and red side of the Bragg wavelength), respectively; the black dashed line in (f) and (g) shows the intensity standing wave pattern of the longitudinal mode bearing the Bragg wavelength.

the same threshold gain breaches the SLM operation condition, which makes the purely refractive index-coupled uniform-grating DFB with a perfect center mirror-symmetric (or antisymmetric) cavity not a SLM laser.

This conclusion can also be generalized to any cavity with the perfect center mirror-symmetry or center mirror-anti-symmetry, once its reflection (or transmission) spectrum is symmetric, a necessary condition to reach the SLM operation is to have its lasing wavelength right in the center of the spectrum. Otherwise, dual-mode operation is inevitable. By recalling the lasing condition for the DBR laser, one may conclude that, in order to ensure its SLM operation with high SMSR, one has to either somehow break the symmetry (or anti-symmetry) of the cavity by, e.g., introducing two slightly different end reflection gratings (usually with slightly misaligned Bragg wavelengths) or use the grating reflector on one end only, or to ensure that the solution to the phase condition (Equation 30.15) is at the Bragg wavelength so that the lasing will happen exactly in the reflection spectrum center.

Since it is impossible to make the purely refractive index-coupled uniform-grating DFB lase at the Bragg wavelength, a conclusion not only drawn from the analysis at the beginning of the discussion on DFB lasers, but also known by the lasing condition (Equation 30.18). This is because for real $\kappa_+\kappa_-L^2$, real γL cannot be a solution as otherwise, the right-hand side is smaller than γL whereas the left-hand side is bigger than γL, hence γL must be complex, which leaves $\delta \neq 0$. The only viable way to reach the SLM operation for such DFB laser is then to break the cavity symmetry (or antisymmetry) by introducing asymmetric facet coatings on the two ends, usually a combination of the AR coating for the front facet and the high-reflection (HR) coating for the rear facet, respectively. However, the SLM yield with high SMSR for such DFB laser is still low since the grating phase at the two ends is usually random, given the condition that the grating period is in 1/5~1/4 of a micrometer whereas the uncertainty of the facet cleaving position is in a range of $\pm(2 \sim 3)\mu m$. Particularly for those DFB lasers with high $\kappa_\pm L$ designs, they usually suffer from very poor SLM yield (only ~15% for $SMSR > 30$ dB with $\kappa_\pm L > 3$) [26]. This is because the DFB laser with high $\kappa_\pm L$ tends to have the envelope of the standing wave pattern piled up in the middle, rather than at the two ends, of the cavity, due to the strong coupling, which makes the cavity less affected by the end facet condition as the waves inside the cavity simply don't "feel" much about the existence of the cavity ends. As a result, the end facet asymmetry applied on a strongly coupled DFB cavity is not sufficient to break the degenerated threshold gain between the two modes. Hence one finds that high $\kappa_\pm L$ often triggers dual mode lasing in DFB lasers. Figure 30.8 shows the standing wave envelope distributions inside the DFB cavity under different coupling strengths, from which one finds that the field stays at the two ends, or piles up in the middle of the cavity, corresponding to the weak (with $\kappa_\pm L < \pi/2$), or strong (with $\kappa_\pm L > \pi/2$) coupling condition, respectively. And the field takes almost an even distribution along the cavity under the critical condition $\kappa_\pm L = \pi/2$, as it has to be.

To thoroughly solve the dual-mode operation problem associated with the purely refractive index-coupled uniform-grating DFB laser, one can have different approaches along with the thought of breaking the cavity symmetry, or forcing the lase at the Bragg wavelength. While the former led to the invention of various complex-coupled DFB lasers [27–30], the latter resulted in the popular product of the QWPS DFB laser [31].

Figure 30.7b shows the working principle of the in-phase partially gain-coupled DFB laser. As an extra gain is introduced periodically inside the high refractive index region, the longitudinal mode with its intensity peak in its standing wave pattern located in the high refractive index region in each period obtains more gain than the other mode, hence the degeneracy between the two longitudinal modes breaks and only the mode with the longer wavelength (on the right/red side of the Bragg wavelength) will lase, which makes such DFB laser operate under SLM. Figure 30.7c shows the working principle by taking the other option to boost the longitudinal mode bearing the shorter wavelength (on the left/blue side of the Bragg wavelength). Known as the antiphase partially gain-coupled DFB laser, the structure has an extra gain introduced periodically inside the low refractive index region, which again breaks the degeneracy between the two longitudinal modes since the longitudinal mode with its intensity peak in its standing wave pattern located in the low refractive index region in each period has more gain than the other

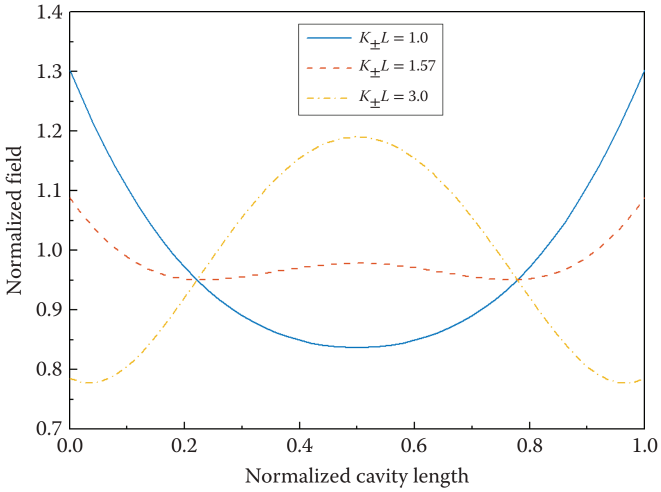

FIGURE 30.8 Field envelope distributions inside the DFB cavity for $\kappa_{\pm}L = 1.0(< 1.57)$, $\kappa_{\pm}L \sim 1.57$, and $\kappa_{\pm}L = 3.0(> 1.57)$.

mode. As a result, only the shorter wavelength mode will lase, which again makes such DFB laser operate under SLM.

Figure 30.7d and e shows the working mechanisms of the partially loss-coupled in-phase and antiphase DFB lasers, respectively. If an extra loss is introduced periodically inside the high (or low) refractive index region, the longitudinal mode with its intensity peak in its standing wave pattern located in the high (or low) refractive index region in each period suffers from more loss than the other mode, hence the degeneracy between the two longitudinal modes breaks and only the mode with the shorter (or longer) wavelength on the left/blue (or right/red) side of the Bragg wavelength will lase, due to the suppression of its counterpart on the other side of the Bragg wavelength, which makes such DFB laser operate under SLM.

One can also understand why the degeneracy breaks in such partially gain- or loss-coupled DFB lasers by the lasing condition (Equation 30.18). For complex-coupled DFBs, $\kappa_+\kappa_-L^2$ is also complex or $\kappa_+\kappa_-L^2 \neq (\kappa_+\kappa_-L^2)^*$. As such, if γ is a solution, γ^* is not necessarily a solution. Following Equation 30.19, one then finds that $\pm\delta$ cannot share the same α as the solutions.

Figure 30.7f shows the working principle of the purely gain-coupled DFB laser. Since the purely gain-coupled laser has a purely negative $\kappa_+\kappa_-$ ($\kappa_- = -\kappa_+^*, \kappa_+\kappa_- = -\kappa_+\kappa_+^* \equiv -|\kappa|^2$), which makes the lasing condition (Equation 30.18) turn into

$$(\gamma L)^2 \coth^2(\gamma L) = (\gamma L)^2 + (|\kappa|L)^2 \tag{30.20}$$

a real solution of γ is then possible which forces the lasing happen at the Bragg wavelength according to Equation 30.19, or

$$\alpha L + j\delta L = \sqrt{(\gamma L)^2 + (|\kappa|L)^2} \tag{30.21}$$

from which one readily achieve $\delta = 0$ for the right-hand side is real. The dual mode lasing in purely gain-coupled DFB laser is not possible as one cannot find two different standing wave patterns inside the cavity that share the same gain. It is obvious that only a single standing wave pattern is allowed inside the cavity with itself completely aligned with the gain grating. Any standing wave pattern in different shape with the gain grating will naturally be suppressed. Therefore, one knows that Equation 30.20 cannot have a complex

γ as its solution associated with the longitudinal mode with the lowest cavity loss (α). As otherwise, γ^* will be an allowed solution as well, according to Equation 30.21, one will then be able to have a pair of lasing wavelengths corresponding to the doubly degenerated solutions $(\alpha, \pm\delta)$, which is in conflict against our previous physics-based analysis on the purely gain-coupled DFB laser cavity. Namely, solution $(\alpha, 0)$ must take the smallest cavity loss $\alpha = \alpha_{\min}$, while any other possible doubly degenerated solutions in the form of $(\alpha, \pm\delta)$ with $\delta \neq 0$ must have a higher cavity loss $\alpha > \alpha_{\min}$ hence cannot be the lasing modes. This conclusion has been evidenced by a numerical searching for all possible solutions of Equation 30.20 [32]. Finally, one may conclude that the purely gain-coupled DFB laser will lase at the Bragg wavelength and naturally stands as the SLM laser.

Figure 30.7g shows the working mechanism of the QWPS DFB laser. The only difference from the uniform-grating purely refractive index-coupled DFB is that there is an extra half period of the grating inserted right at the cavity center. An extra half period of the grating is equivalent to a quarter-wavelength phase shift in the first-order grating following the relationship between the grating period and the Bragg wavelength $\Lambda = \lambda_B/(2n_{\text{eff}})$, which therefore introduces a π phase shift to the reflected wave or a π phase shift to the round trip wave. As such, the wave will have to make two round trips to recover its status, which leads to its resonance. This feature suggests us to fold back the cavity from the center to equivalent the original structure to a uniform-grating DFB with half of its original length and with a perfect facet with 100% reflectivity at one end (the original cavity center). In such a half cavity equivalent structure, if the standing wave pattern has its intensity peak originally aligned with the high refractive index region in every period, upon the 100% reflection at one end, the peak will have to be aligned with the low refractive index region in every period, and vice versa. As such, none of the two original standing wave patterns inside the uniform-grating DFB can exist inside the modified cavity with a quarter-wavelength phase shift introduced at the cavity center. Rather, only a standing wave pattern with its peak aligned at the edge of the grating tooth (i.e., the interface of the high and low refractive index region) in every period can stay. This standing wave pattern is unique inside the cavity and corresponds to the longitudinal mode at the Bragg wavelength, for it sees an averaged refractive index between the high and low index region in every period, which happens to be the effective index of the unperturbed waveguide by the grating. Also physically, a longitudinal mode with its envelope piled up in the middle of the cavity will see the highest reflection from both sides if it bears the Bragg wavelength. Hence this mode will be most tightly confined inside the cavity and sees the most gain. Consequently, it should have the lowest cavity loss and becomes the lasing mode. The numerically calculated longitudinal mode distribution along the cavity of such structure confirms this conclusion [33] as one finds that, with its lasing mode always at the Bragg wavelength, the QWPS DFB laser has a sharp longitudinal mode distribution peak at the center of the cavity. In a uniform-grating DFB without a phase-shifted center inside the cavity, this scenario can never happen, as the maximum reflection at the Bragg wavelength can only be possibly seen by the wave from one side rather than from both sides. Hence the wave at the Bragg wavelength cannot stay long inside the cavity to obtain sufficient gain for lasing, a same conclusion drawn earlier for the uniform-grating purely refractive index-coupled DFB laser. It is worth mentioning that a more detailed analysis would have to have a new lasing condition involved as Equation 30.17 is no longer valid for either a nonuniform grating (the grating with a phase shift) or a uniform grating with nonzero end facet reflection (the equivalently folded cavity with a uniform grating plus 100% reflection at one end). From the newly derived lasing condition for this structure, one will be able to find that $\delta = 0$ is indeed an allowed solution that has the minimum cavity loss ($\alpha = \alpha_{\min}$) [34]. Therefore, the QWPS DFB laser always operates under the SLM and has its lasing mode at the Bragg wavelength.

30.2.4 Governing Equations for Design, Modeling, and Simulation

The following one-dimensional (along the propagation direction, z) traveling wave model is often used as the optical governing equation for the edge-emitting semiconductor lasers with various waveguide-grating structures [16]:

$$
\begin{aligned}
\left(\frac{1}{v_g}\frac{\partial}{\partial t}+\frac{\partial}{\partial z}\right)e^f(z,t) &= [j\left(\frac{2\pi n_{\text{eff}}}{\lambda_0}-\frac{\pi}{\Lambda}\right)+j\frac{2\pi}{\lambda_0}\Gamma\Delta n(z,t,\omega_0) \\
&\quad +\frac{1}{2}\Gamma g(z,t,\omega_0)-\frac{1}{2}\alpha_L]e^f(z,t)+j\kappa_+e^b(z,t)+s^f(z,t) \\
\left(\frac{1}{v_g}\frac{\partial}{\partial t}-\frac{\partial}{\partial z}\right)e^b(z,t) &= [j\left(\frac{2\pi n_{\text{eff}}}{\lambda_0}-\frac{\pi}{\Lambda}\right)+j\frac{2\pi}{\lambda_0}\Gamma\Delta n(z,t,\omega_0) \\
&\quad +\frac{1}{2}\Gamma g(z,t,\omega_0)-\frac{1}{2}\alpha_L]e^b(z,t)+j\kappa_-e^f(z,t)+s^b(z,t)
\end{aligned}
\tag{30.22}
$$

where $e^{f,b}$ denote the slow-varying envelopes of the forward and backward going traveling wave field, respectively, g and Δn the material gain and refractive index change, respectively, α_L the non-interband optical modal loss, ω_0 the reference optical frequency, $\lambda_0 = 2\pi c/\omega_0$ the reference optical wavelength (i.e., the vacuum wavelength of the reference optical frequency), $v_g = c/n_g$ the group velocity, n_{eff} and Γ the effective index (of the waveguide) and confinement factor (of the active region), respectively, Λ and $\kappa_\pm$ the period, the backward-to-forward (+), and the forward-to-backward (−) coupling coefficient of the first-order waveguide Bragg grating, respectively, $s^f = s^b \equiv \tilde{s}$ the spontaneous emission contributions.

The associated optical field can be expressed as

$$
\vec{E}(x,y,z,t) = \frac{1}{2}\vec{s}\varphi(x,y)[e^f(z,t)e^{j\frac{\pi}{\Lambda}z}+e^b(z,t)e^{-j\frac{\pi}{\Lambda}z}]e^{-j\omega_0 t}+c.c. \tag{30.23}
$$

with $\vec{s}$ indicating the unit vector of along the (linear) field polarization direction, φ the field distribution of the waveguide mode as the solution of Equation 30.9. For a given waveguide-grating structure, one needs to solve Equation 30.9 first to find the effective index (n_{eff}) and the guided mode field distribution (φ). The coupling coefficients ($\kappa_\pm = \kappa_{\pm 1}$) can then be obtained from Equation 30.8 and the confinement factor is given as

$$
\Gamma = \int_{A.R.} |\varphi(x,y)|^2 dxdy \Big/ \int_{\Sigma} |\varphi(x,y)|^2 dxdy \tag{30.24}
$$

with the integration areas $A.R.$ and Σ indicating the active region (quantum wells) only and the whole area where the optical field extends.

Equation 30.22 is obtained from the optical wave equation under the slow-varying envelope approximation with the second-order derivatives of the envelope ($\partial^2 e^{f,b}/\partial z^2$ and $\partial^2 e^{f,b}/\partial t^2$) all ignored, whereas the optical wave equation is directly obtained from the Maxwell equations with the coupling among the field polarization components $\nabla(\nabla \cdot \vec{E})$ ignored. The former is true for the edge-emitting device with its cavity length L much longer than the operating wavelength λ (usually L is in a few hundreds to a thousand of λ/n_{eff}), in which the optical wave is propagating along the cavity with its traveling wave factors $\phi_\pm = e^{j(\pm\pi z/\Lambda-\omega_0 t)}$ varying much faster as z and t, hence:

$$
\begin{aligned}
|\partial^2 e^{f,b}/\partial z^2/e^{f,b}| &<< |\partial^2\phi_\pm/\partial z^2/\phi_\pm| = (\pi/\Lambda)^2 \\
|\partial^2 e^{f,b}/\partial t^2/e^{f,b}| &<< |\partial^2\phi_\pm/\partial t^2/\phi_\pm| = \omega_0^2
\end{aligned}
\tag{30.25}
$$

The latter assumption holds for the weakly confined waveguide, which is generally true of most of the III–V compound semiconductor laser diodes with either ridge waveguide or buried heterojunction structures.

In the field expansion (Equation 30.23), the single-guided-mode assumption has been invoked as a necessary condition for the SLM operation. As different guided modes have different effective indices, for the same grating period Λ, different wavelengths will be chosen to satisfy the phase-matching condition (Equation 30.4). As a result, multiple longitudinal modes in different lasing wavelengths, with each of them corresponding to a guided mode in a different effective index, will be excited, which breaches the SLM condition. A single polarization component is assumed for the same reason, but this is not necessary as the difference between the two effective indices corresponding to the two orthogonally polarized components in a guided mode is usually very small in weakly confined waveguides. As a result, the difference between their corresponding lasing wavelengths can hardly be appreciable. Actually, for most of the III–V compound semiconductor laser diodes, the active region is made of the compressively strained multiple quantum wells (CS-MQW). The compressively strained quantum well can only provide the optical gain in the (100) plane [35], which means only the TE mode with its optical E-field polarized in parallel to the slab waveguide interfaces, i.e., the interfaces of the layer stack grown in the usual <100>direction, can see the gain whereas the other polarization component, i.e., the TM mode with its E-field polarized in the perpendicular direction, will be completely suppressed. Therefore, it is usually sufficient to study the TE mode with its E-field horizontally polarized in parallel with the device top and bottom surfaces.

The material gain of semiconductors can generally be calculated by the physics-based first-principles model [16]. For performance simulation of the SLM laser, however, the following model that phenomenologically links the gain to the (minority) carrier density inside the active region is sufficient:

$$g(z,t,\omega_0) = a(\omega_0)\ln\frac{N(z,t)}{N_{\text{tr}}(\omega_0)}/[1+\varepsilon(|e^f(z,t)|^2+|e^b(z,t)|^2)] \tag{30.26}$$

with $a(\omega_0)$ and $N_{\text{tr}}(\omega_0)$ indicating the gain coefficient and the transparent (minority) carrier density for the active region comprising (strained-layer) multiple quantum wells, ε the nonlinear gain saturation factor. These parameters are usually extracted in the neighborhood of the reference optical frequency (ω_0) from the physics-based material gain model or measured experimentally.

The refractive index change and the material gain, corresponding to the real and imaginary part of the material susceptibility, are connected by the Kramers–Kronig relation. Actually, if one views the susceptibility as the frequency-domain transfer function of the material system in responding to the optical E-field as the input signal, the polarization excited by the optical E-field then becomes the output signal. Following the linear system theory, the time-domain polarization is given as the convolution of the time-domain optical E-field and the inverse Fourier transform of the susceptibility. Since a real physical system must be causal, which means the polarization at any time instant t can only be dependent on the optical E-field given before t, it imposes a strong constraint between the real and imaginary part of the susceptibility and is mathematically given in the form of the Kramers–Kronig transform. By noticing that the SLM laser is a typical narrow-band device with its lasing frequency in the neighborhood of the reference optical frequency (ω_0) and the Kramers–Kronig relation is linear, one can readily express the refractive index change as a linear function of the material gain:

$$\Delta n(z,t,\omega_0) = \alpha_{\text{LEF}}\, g(z,t,\omega_0) \tag{30.27}$$

with α_{LEF} denoting the linewidth enhancement factor.

Finally, the carrier density inside the active region can be described by the following rate equation [16,36]:

$$\begin{aligned}\frac{\partial N(z,t)}{\partial t} &= \frac{I(z,t)}{qV} - [AN(z,t)+BN^2(z,t)+CN^3(z,t)]\\ &\quad -\frac{n_{\text{eff}}}{2\hbar\omega_0}\sqrt{\frac{\varepsilon_0}{\mu_0}}\frac{L\Gamma}{V}g(z,t,\omega_0)[|e^f(z,t)|^2+|e^b(z,t)|^2]\end{aligned} \tag{30.28}$$

where I represents the bias current; q the unit electron charge; V the active region volume; A, B, and C the minority carrier Shockley–Read–Hall (SRH); bimolecular and spontaneous emission, and Auger recombination coefficients, respectively; $\hbar$ Plank constant; $\sqrt{\varepsilon_0/\mu_0} \approx 1/377[\mathrm{S}]$ the vacuum admittance; and L the active region length (along the cavity direction). Given the fact that the active region of the laser diode has a low (unintentional) doping concentration and the potential drop across it is usually negligible, a quasi-neutrality condition holds and consequently the electrons and holes have the same density inside the active region—we therefore don't have to distinguish the electron and hole density and simply use the term "carrier density" to indicate both.

As the seed of the lasing process, the spontaneous emission contribution cannot be ignored at the beginning as otherwise Equation 30.22 becomes homogenous and only the trivial zero solution exists. Once the lasing starts, i.e., for the device operated under a bias beyond the threshold, however, the contribution from the spontaneous emission becomes negligible, which is reflected as a fact that the self-consistent solution of the above set of equations always converges to the same value regardless of the excitation method of the spontaneous emission, as long as the spontaneously emitted noise power is self-consistently described. The spontaneous emission contribution is usually assigned as a Gaussian distributed zero-mean random variable with its autocorrelation function normalized by the spontaneously emitted noise power [16]:

$$< |\tilde{s}(z,t)||\tilde{s}(z',t')| > = \frac{2\hbar\omega_0}{n_{\mathrm{eff}}}\sqrt{\frac{\mu_0}{\varepsilon_0}}\gamma\Gamma n_{sp} g(z,t,\omega_0)\delta(z-z')\delta(t-t') \tag{30.29}$$

where γ denotes the dimensionless coefficient of the coupling from the spontaneous emission to the entire spatial sphere and over the whole frequency spectrum to the waveguide mode at the reference optical frequency, n_{sp} the dimensionless ratio of the spontaneous emission to stimulated emission gain, and δ the Dirac function.

Equations 30.22, and 30.26 through 30.29 form a closed loop for one to find a set of self-consistent solution on the (minority) carrier density inside the active region (N), the material gain (g), and the slow-varying envelopes of the forward and backward going traveling wave field ($e^{f,b}$), for any given bias (I), with Equations 30.9, 30.8 and 30.24 presolved for a given SLM laser structure. Consequently, the optical field inside the laser can be found through Equation 30.23 and other physics quantities for characterizing the laser, such as the output optical power and the lasing wavelength, can readily be found [16,37]. An efficient solution technique for solving Equation 30.22 is to use the time-domain split-step method [38], with Equation 30.28 solved by the well-known Runge–Kutta method [39].

To describe the thermal effect, one still needs to add on the thermal diffusion equation [40] and to modify the empirical formulas for the material gain and refractive index change by considering their temperature dependence [16]. However, we will exclude the thermal description in this model to focus our study on the SLM operation aspect of semiconductor laser diodes.

30.2.5 Examples of SLM Laser Characteristics

By exploiting the aforementioned model, one can calculate the device performance for SLM DFB lasers with a few different types of grating structures as discussed in Section 30.2.3, shown in Figures 30.5 and 30.7. Figures 30.9 through 30.14 show the numerical simulation results of the output optical power and lasing wavelength as functions of the bias, the optical spectra at a fixed bias, the normalized optical field intensity and (minority) carrier density distributions along the cavity, and the small-signal intensity modulation responses for the purely refractive index-coupled uniform-grating DFB, partially gain/loss-coupled in/antiphase DFB, purely gain-coupled DFB, and QWPS DFB, respectively, with those device parameters involved in the model summarized in Table 30.1.

From Figure 30.9, one finds that while all DFB lasers have similar threshold current, the loss-coupled and QWPS DFB lasers have lower slope efficiency. This is expected for loss-coupled DFB lasers as their loss-coupling coefficient introduces an extra contribution equivalent to the non-interband optical modal

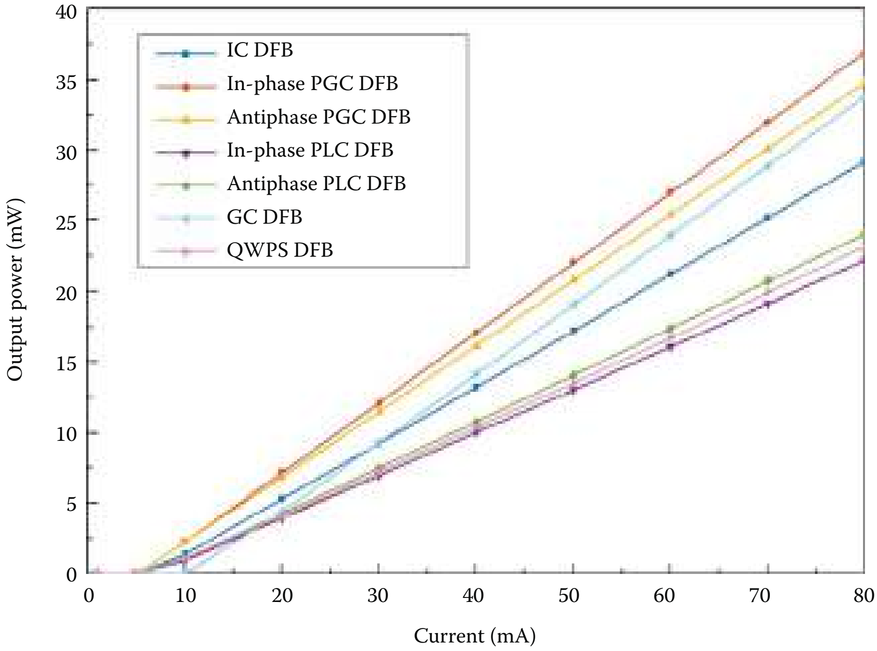

FIGURE 30.9 Output power–bias current curves for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted.

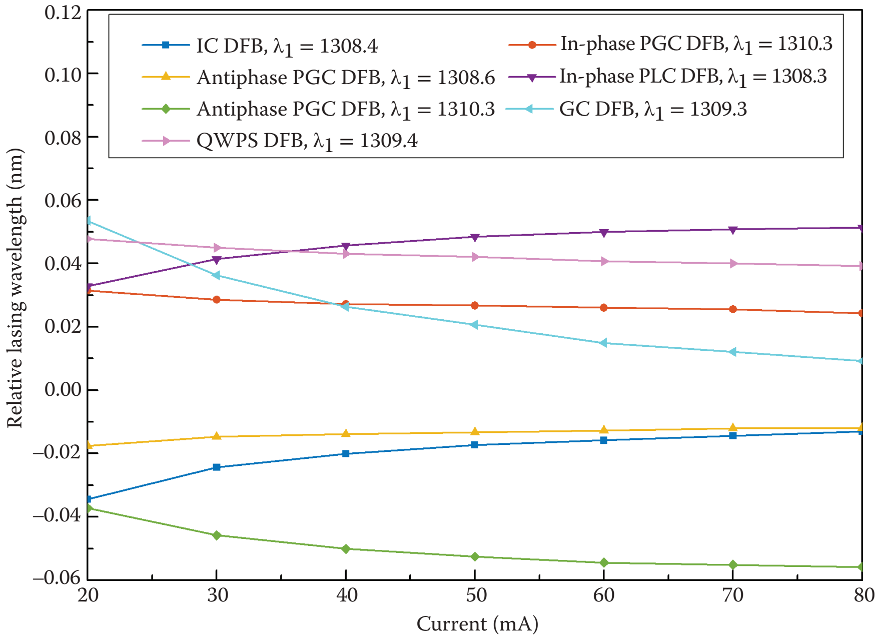

FIGURE 30.10 Relative lasing wavelength shift–bias current curves for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted; the relative lasing wavelength shift is defined as λ-λ_l, with λ indicating the lasing wavelength at any bias current > 20 mA and λ_l the lasing wavelength at bias current = 20 mA for different DFB lasers under comparison.

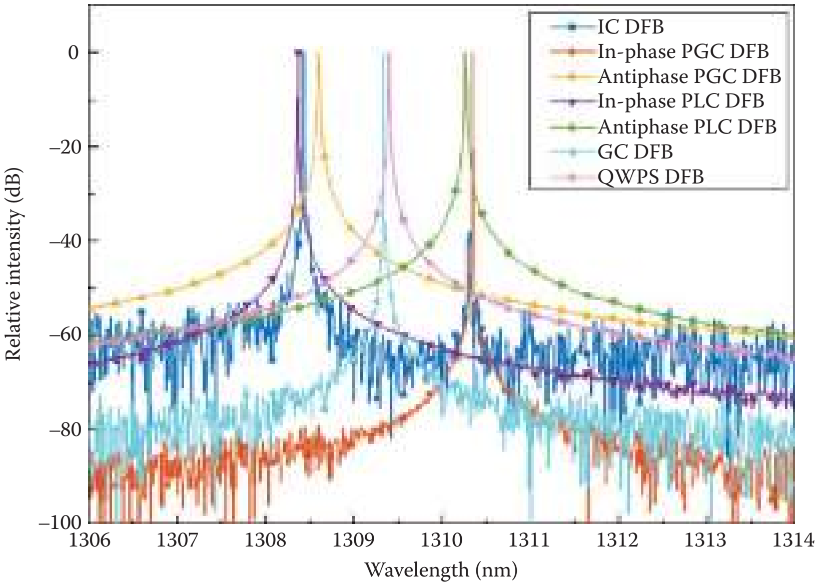

FIGURE 30.11 Lasing spectra for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted.

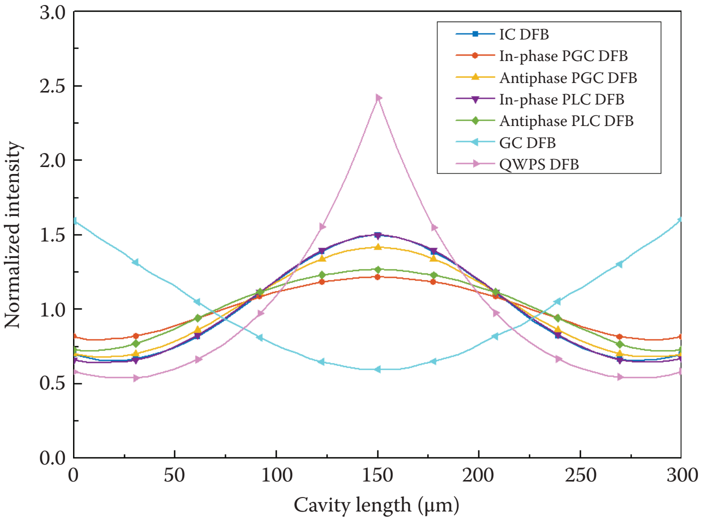

FIGURE 30.12 Normalized optical field intensity distributions for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted.

loss (α_L). As shown in Table 30.1, the assumed non-interband optical modal loss is 10/cm, the normalized loss-coupling coefficient 0.5 would give an extra optical loss around 0.5/L = 0.5/(0.03 cm) ~17/cm. The total optical loss 27/cm indicates a significant increase as compared the original value in 10/cm. Since the slope efficiency is inversely proportional to the optical modal loss, higher loss would certainly cause a lower efficiency. The low slope efficiency of the QWPS DFB laser, however, is not caused by the high

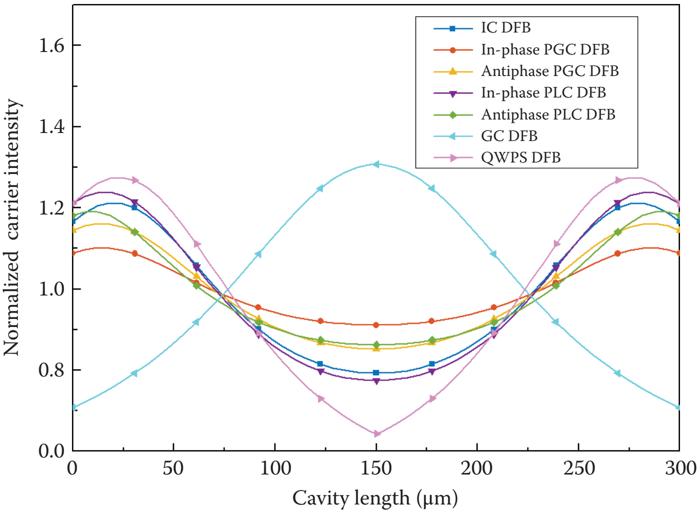

FIGURE 30.13 Normalized (minority) carrier density distributions for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted.

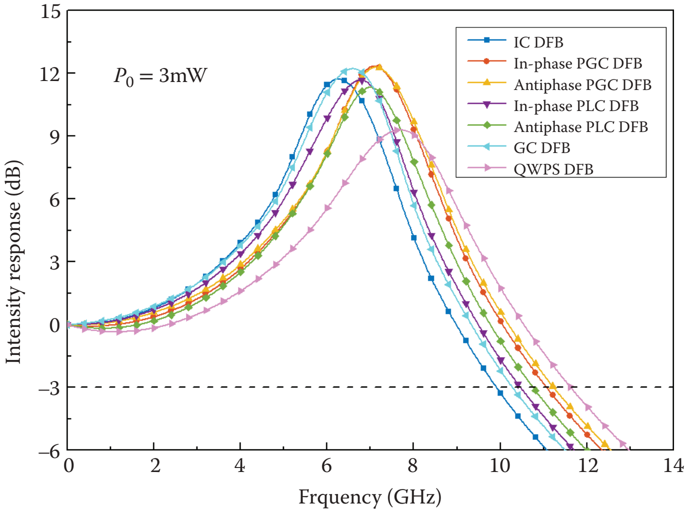

FIGURE 30.14 Small-signal intensity modulation responses for different DFB lasers. IC = (purely refractive) index-coupled (uniform grating), PGC = partially gain-coupled, PLC = partially loss-coupled, GC = (purely) gain-coupled, QWPS = quarter-wavelength phase-shifted.

optical modal loss, but by the low cavity loss. Since this structure has its field intensity mostly concentrated in the middle of the cavity, such a field pattern tends to retain more photons inside the cavity and consequently leads to a low output power by the low field distribution at both facets. This is consistent with our understanding on QWPS DFB as a high Q (quality)-factor laser with low cavity loss. Still because the slope efficiency is determined by the cavity loss over the summation of the cavity loss and the optical modal loss, apparently a low cavity loss will lead to a low slope efficiency once the optical modal loss is a nonvanishing positive value.

TABLE 30.1 Model Parameters

Model Parameter	Value
Cavity length L (μm)	300
Thickness of the quantum well (nm)	5
Number of quantum wells	6
Reflectivity of both laser facets	0, 0
Group index n_g	3.6
Effective index n_{eff}	3.2
Confinement factor Γ	0.06
Ridge width (μm)	2
Normalized index coupling coefficient	2.5
Normalized gain coupling coefficient	0.5
Normalized loss coupling coefficient	0.5
Grating period Λ (nm)	204.7
Gain coefficient a (cm^{-1})	1800
Transparent carrier density N_{tr} (10^{18} cm^{-3})	0.8
Linewidth enhancement factor α_{LEF}	−3
Nonlinear gain saturation factor ε (10^{-2} V^{-2})	9
SRH recombination coefficient A (10^9 s^{-1})	1
Bimolecular and spontaneous emission recombination coefficient B (10^{-10} $\text{cm}^{-3}\text{s}^{-1}$)	2
Auger recombination coefficient C (10^{-29} cm^{-6} s^{-1})	4
Non-interband modal loss α_L (cm^{-1})	10
Spontaneous emission coupling coefficient γ	10^{-4}
Spontaneous emission over stimulated emission ration_{sp}	1.7
Reference wavelength λ_0 (μm)	1.310

As ideal laser characteristics, the carrier density as well as the averaged gain should be clamped after lasing, but this is true only when the carrier density and optical field intensity both have uniform distributions along the cavity. In DFB lasers, however, the carrier density and optical field intensity have nonuniform distributions in "opposite" shapes as shown in Figure 30.12. Also, following the Schwartz nonequality, one knows the fact that the overlap integration between two functions with different shapes must be smaller than that between two functions in a similar shape. Under higher bias current, stronger LSHB makes the carrier density and optical field intensity distribution shapes more unlike. As a quantity directly in proportion to the overlap integration of the carrier density and optical field intensity distributions along the cavity, the averaged gain will be smaller. To maintain the lasing status, i.e., to balance the cavity loss plus the optical non-interband modal loss, the carrier density will have to increase with the bias current in order to compensate the "lost" averaged gain due to the enhanced LSHB. The increased carrier density will therefore cause a refractive index reduction of the active region following the Kramers–Kronig relation, which is simplified as Equation 30.27 with the negative linewidth enhancement factor (α_{LEF}). The reduction of the active region refractive index brings down the effective index of the waveguide and consequently makes the Bragg wavelength as well as the whole Bragg stop-band shift toward the shorter wavelength side, according to Equation 30.4 ($\lambda_B = 2n_{\text{eff}}\Lambda$). This effect is indeed reflected in Figure 30.10 by the blueshift with the increased bias current of the lasing wavelengths of the QWPS DFB and GC DFB lasers, located right in the center of the Bragg stop-band (or at the Bragg wavelength).

Figure 30.10 also shows that, without the thermal effect considered in simulation, the lasing wavelengths of the DFB lasers on the left (blue) side the Bragg stop-band (i.e., the IC DFB, the antiphase PGC DFB, and the in-phase PLC DFB; see Figure 30.11) have redshift toward the longer wavelength side with increased bias current, whereas the lasing wavelengths of the DFB lasers on the right (red) side (i.e., the in-phase PGC DFB and the antiphase PLC DFB; see Figure 30.11) take blueshift toward the shorter wavelength side. This is brought in by the shrinkage of the Bragg stop-band width due to the enhanced LSHB with the increased bias current, which further suggests an effective normalized coupling coefficient reduction or a more opened (lower Q-factor) cavity in accompanying with the stronger LSHB under higher injection level.

Figure 30.11 clearly shows that the QWPS and purely gain-coupled DFB lasers lase at the Bragg wavelength, whereas the in-phase and antiphase partially gain-coupled DFB lasers have their lasing wavelengths at the right (red) and left (blue) side of the Bragg stop-band, respectively. The in-phase and antiphase partially loss-coupled DFB lasers have their lasing wavelengths located the other way around, at the left (blue) and right (red) side of the Bragg stop-band, respectively. Finally, the purely refractive index-coupled DFB laser picks the left (blue) side wavelength rather randomly, with a relatively poor SMSR as expected. All these findings are consistent with previous analysis on these DFB lasers with different grating designs.

From Figure 30.12, one finds that the QWPS DFB laser has its field intensity mostly gathered in the middle of the cavity, as opposed to the purely gain-coupled DFB laser with its field intensity largely concentrated at both edges. The former cavity obviously bears the highest Q-factor or smallest cavity loss, whereas the latter one must correspond to the lowest Q-factor or highest cavity loss. Since the threshold current is proportional to the cavity loss, and the slope efficiency also increases with the cavity loss, the high Q-factor QWPS DFB laser bearing a low cavity loss has a low threshold current and a low slope efficiency. On the contrary, the low Q-factor purely gain-coupled DFB laser bearing a high cavity loss has a high threshold current as well as a high slope efficiency. This result has been confirmed by Figure 30.9 exactly. Other DFB lasers have their field intensities more evenly distributed and have their cavity losses in between. Consequently, they have their threshold current and slope efficiency values in between as shown in Figure 30.9. It is also worth mentioning that the sharp field turning in the middle of the QWPS DFB laser cavity is brought in by the half grating period shift exactly at the same location.

All carrier density distributions take the opposite shape as compared to their optical field intensity distributions. This result is expected as the carriers inside the cavity are consumed to generate photons, indicating a low carrier density wherever the optical field intensity is high, and vice versa.

Simulation result shows that there is no significant difference in terms of the 3 dB small-signal intensity modulation bandwidth among different DFB lasers once they are set to output the same optical power. This is quite different from the result obtained in References [41,42], in which the antiphase partially gain-coupled DFB laser shows a significantly broader 3 dB small-signal intensity modulation bandwidth in comparison with its in-phase counterpart. The inconsistency might come from the different selection on device parameters and further investigation is still needed before a final conclusion can be achieved.

30.3 Coupled-Cavity Single Longitudinal Mode Laser Diodes

30.3.1 A General Optical (Band-Pass) Filtering Model

The conventional FP cavity supports many closely packed longitudinal cavity modes with their spacing given in the form of Equation 30.2. For the edge-emitting laser with its cavity length (L) much longer than the center wavelength (λ_0), the mode spacing is much smaller than the full width at half maximum (FWHM) of the material gain peak. As such, multiple longitudinal modes can lase simultaneously, which makes a typical edge-emitting FP laser operate under the multiple longitudinal mode lasing scheme. Other than the aforementioned grating-assisted methods by introducing the wavelength-selective end reflectors (DBR), or by exploiting various DFB cavities, to achieve the SLM operation, one can still take an alternative approach by inserting an optical (band-pass) filter into the FP cavity to eliminate all other longitudinal cavity modes but leave only one for lasing. This approach is generally known as the coupled-cavity laser that forms the other category of SLM lasers, if we don't count in various external cavity SLM laser configurations.

For a coupled-cavity laser generally presented in the form of an FP cavity with an inserted OBPF shown in Figure 30.15, we have [43]:

$$\begin{bmatrix} A_{\text{out}} \\ B_{\text{out}} \end{bmatrix} = \frac{1}{T^2}\begin{bmatrix} 1 & -R \\ -R & 1 \end{bmatrix}\begin{bmatrix} e^{j\varphi_2} & 0 \\ 0 & e^{-j\varphi_2} \end{bmatrix}\frac{1}{t_{21}}\begin{bmatrix} t_{12}t_{21} - r_{12}r_{21} & r_{21} \\ -r_{12} & 1 \end{bmatrix}\begin{bmatrix} e^{j\varphi_1} & 0 \\ 0 & e^{-j\varphi_1} \end{bmatrix}\begin{bmatrix} 1 & R \\ R & 1 \end{bmatrix}\begin{bmatrix} A_{\text{in}} \\ B_{\text{in}} \end{bmatrix} \tag{30.30}$$

with $A_{\text{in,out}}$ and $B_{\text{in,out}}$ denoting the optical field amplitude of the forward and backward propagating waves, with their subscript "in" and "out" indicating the assumed input and output port on the left- and right-hand sides, respectively. One should note that the optical field is polarized in the cross-sectional plane perpendicular to the cavity direction. The arrows associated with them in Figure 30.15 indicate their propagation direction, not their polarization direction. Also in Equation 30.30, R and T indicate the amplitude reflectivity and transmissivity of the end facets when looking from inside of the FP cavity, $r_{12,21}$ the amplitude reflectivities when looking from the FP cavity to the OBPF on the left- and right-hand sides, $t_{12,21}$ the amplitude transmissivities from left to right and from right to left when staying inside the FP cavity, respectively. Finally, $\varphi_{1,2}$ are the phase delays of the wave traveling through the two sections ($L_{1,2}$) of the FP cavity separated by the OBPF.

Equation 30.30 can readily be simplified to

$$\begin{aligned} \begin{bmatrix} A_{\text{out}} \\ B_{\text{out}} \end{bmatrix} &= \frac{1}{t_{21}T^2}\begin{bmatrix} e^{j\varphi_2} & -Re^{-j\varphi_2} \\ -Re^{j\varphi_2} & e^{-j\varphi_2} \end{bmatrix}\begin{bmatrix} \delta & r_{21} \\ -r_{12} & 1 \end{bmatrix}\begin{bmatrix} e^{j\varphi_1} & Re^{j\varphi_1} \\ Re^{-j\varphi_1} & e^{-j\varphi_1} \end{bmatrix}\begin{bmatrix} A_{\text{in}} \\ B_{\text{in}} \end{bmatrix} \\ &\equiv \frac{1}{t_{21}T^2}\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}\begin{bmatrix} A_{\text{in}} \\ B_{\text{in}} \end{bmatrix} \end{aligned}, \tag{30.31}$$

where

$$\delta \equiv t_{12}t_{21} - r_{12}r_{21} \text{ and } A_{22} \equiv e^{-j(\varphi_2+\varphi_1)} - r_{12}Re^{-j(\varphi_2-\varphi_1)} - r_{21}Re^{j(\varphi_2-\varphi_1)} - \delta R^2 e^{j(\varphi_2+\varphi_1)} \tag{30.32}$$

The lasing condition is therefore obtained as $A_{\text{in}} = B_{\text{out}} = 0$, but A_{out} and B_{in} are not zero, which requires $A_{22} = 0$, or:

$$[r_{12}e^{-j(\varphi_2-\varphi_1)} + r_{21}e^{j(\varphi_2-\varphi_1)}]Re^{j(\varphi_2+\varphi_1)} + \delta R^2 e^{2j(\varphi_2+\varphi_1)} = 1 \tag{30.33}$$

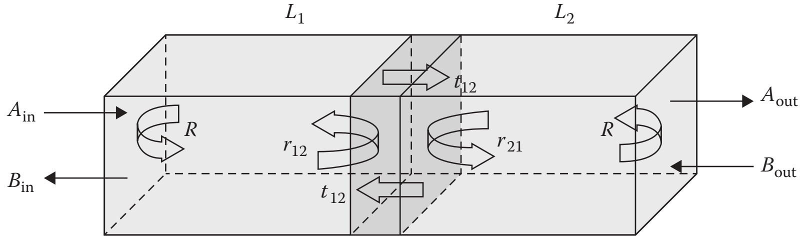

FIGURE 30.15 An illustrative diagram showing the FP cavity with an inserted optical band-pass filter (OBPF), with A_{in} and B_{in}, A_{out} and B_{out} indicating the optical field amplitudes of the forward and backward propagating waves at the input and output port, respectively; r_{12} and t_{12} the amplitude reflectivity and transmissivity from the left section to the inserted OBPF; r_{21} and t_{21} the amplitude reflectivity and transmissivity from the right section to the inserted OBPF; $L_{1,2}$ the lengths of the left and right section, respectively; R the end facet amplitude reflectivity of the FP cavity.

1. FP cavity
   It is obvious that once we remove the OBPF by letting $r_{12} = r_{21} = 0$ and $\delta = 1$, Equation 30.33 reduces to the well-known lasing condition of the FP laser:

$$R^2 e^{2j(\varphi_2+\varphi_1)} = 1 \tag{30.34}$$

2. Bidirectional symmetric filter
   Once the OBPF has the bidirectional symmetry, by letting

$$r_{12} = r_{21} = jre^{j\theta} \tag{30.35}$$

   and

$$t_{12} = t_{21} = te^{j\theta} \tag{30.36}$$

   we have

$$\delta = (t^2 + r^2)e^{2j\theta} \equiv (1 - l)e^{2j\theta} \tag{30.37}$$

   where θ and l stand for the single pass phase and loss of the filter, respectively. Hence we find from Equation 30.33:

$$2jrR\cos(\varphi_2 - \varphi_1)e^{j(\varphi_2+\varphi_1+\theta)} + (1 - l)R^2 e^{2j(\varphi_2+\varphi_1+\theta)} = 1 \tag{30.38}$$

   It is apparent that Equation 30.38 can be rewritten as

$$\bar{R}^2 e^{2j(\varphi_2+\varphi_1+\theta)} = 1, \text{ with } \bar{R} \equiv \sqrt{\frac{1-l}{1 - 2rR\cos(\varphi_2 - \varphi_1)e^{j(\varphi_2+\varphi_1+\theta+\pi/2)}}}R \tag{30.39}$$

   Unlike in Equation 30.34 where the amplitude reflectivity of the end facets R is a constant for a conventional FP laser, a coupled-cavity laser comprising an FP cavity with an inserted bidirectional symmetric filter has a wavelength-dependent effective amplitude reflectivity in its lasing condition, which, conceptually similar to the lasing condition of the DBR laser given as Equation 30.13, provides an extra wavelength selection mechanism to make a conventional FP laser single-moded. For example, if the inserted filter is lossless ($l = 0$), Equation 30.39 shows that the modification on the lasing condition from the original FP cavity is determined by the reflection (r) and length (θ) of the filter and its position inserted inside the FP cavity (φ_1 and φ_2). It is possible that, within the wavelength range set by the gain spectrum bandwidth, there is a single wavelength that makes $1 - 2rR\cos(\varphi_2 - \varphi_1)e^{j(\varphi_2+\varphi_1+\theta+\pi/2)} = 1 - 2|r|R$, and $2(\varphi_1 + \varphi_2 + \theta) = 2m\pi$, with m as an integer. Hence $\bar{R}$ will be the maximum with the round trip phase-matching condition satisfied at this wavelength. As a result, the lasing will only happen at this wavelength and such a general coupled-cavity structure supports SLM operation.

In the fabrication of real-world coupled-cavity lasers, the OBPF is usually formed by an equivalent FP etalon. The filter reflectivity and transmissivity in Equations 30.35 and 30.36 can then be derived from Equation 30.30 itself with the inserted filter removed from the FP cavity in Figure 30.15. By doing so, we find that Equation 30.30 reduces to

$$\begin{aligned}\begin{bmatrix} A'_{\text{out}} \\ B'_{\text{out}} \end{bmatrix} &= \frac{1}{T'^2}\begin{bmatrix} 1 & -R' \\ -R' & 1 \end{bmatrix}\begin{bmatrix} e^{j\varphi'} & 0 \\ 0 & e^{-j\varphi'} \end{bmatrix}\begin{bmatrix} 1 & R' \\ R' & 1 \end{bmatrix}\begin{bmatrix} A'_{\text{in}} \\ B'_{\text{in}} \end{bmatrix} \\ &= \frac{1}{T'^2}\begin{bmatrix} e^{j\varphi'}(1 - R'^2 e^{-2j\varphi'}) & 2jR'\sin\varphi' \\ -2jR'\sin\varphi' & e^{-j\varphi'}(1 - R'^2 e^{2j\varphi'}) \end{bmatrix}\begin{bmatrix} A'_{\text{in}} \\ B'_{\text{in}} \end{bmatrix}\end{aligned}$$

with the prime symbols added to the variables and parameters to differentiate them from those being used in Equation 30.30 for the most outside FP cavity in Figure 30.15. In the absence of the incident light coming from the left-hand side, $B'_{\text{out}} = 0$, we have

$$R_f \equiv \frac{B'_{\text{in}}}{A'_{\text{in}}} = j\frac{2R' \sin\varphi' e^{j\varphi'}}{1 - R'^2 e^{2j\varphi'}}, \text{ and } T_f \equiv \frac{A'_{\text{out}}}{A'_{\text{in}}} = \frac{T'^2 e^{j\varphi'}}{1 - R'^2 e^{2j\varphi'}}$$

Since the common factor $1/(1 - R'^2 e^{2j\varphi'})$ in abovementioned expressions can be expanded in a form of

$$1 + R'^2 e^{2j\varphi'} + (R'^2 e^{2j\varphi'})^2 + \ldots$$

which means that $j2R' \sin\varphi' e^{j\varphi'}$ and $T'^2 e^{j\varphi'}$ are the single pass reflectivity and transmissivity, respectively, Equations 30.35 and 30.36 are valid once we take

$$r = 2R' \sin\varphi' \tag{30.40}$$

$$t = T'^2 \tag{30.41}$$

and

$$\theta = \varphi' \tag{30.42}$$

Equations 30.35 through 30.37 and Equations 30.40 through 30.42 therefore link the model parameters to the design parameters of the physical structure.

30.3.2 Cleaved-Coupled-Cavity (C^3) Laser

A typical cleaved-coupled-cavity (C^3) laser has a structure shown in Figure 30.16.

Following the general coupled-cavity laser model derived in Section 30.3.1, we have

$$R' = (n_{\text{eff}} - 1)/(n_{\text{eff}} + 1) \tag{30.43}$$

$$T'^2 = 4n_{\text{eff}}/(n_{\text{eff}} + 1)^2 \tag{30.44}$$

$$\varphi' = 2\pi d/\lambda \tag{30.45}$$

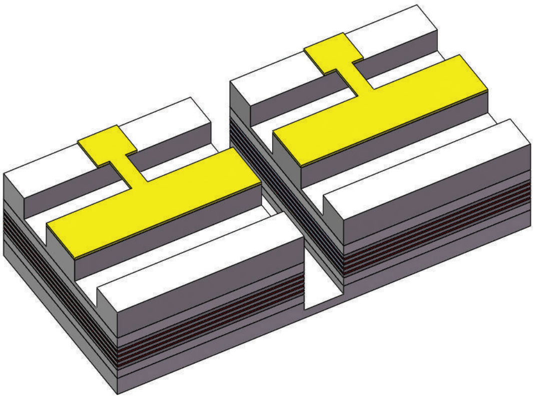

FIGURE 30.16 The C^3 laser structure.

with n_{eff} denoted as the laser waveguide effective index and d the air gap spacing between the pair of coupled cavities. By noting

$$\varphi_{1,2} = [2\pi n_{\text{eff}}/\lambda - j(g - \alpha_i)]L_{1,2} \tag{30.46}$$

and using Equations 30.40 through 30.42, one can express the lasing condition (Equation 30.39) in terms of the C^3 laser design parameters ($n_{\text{eff}}, d, g, \alpha_i, L_{1,2}$). The SLM lasing condition can therefore be found by a proper combination of the two cavity lengths ($L_{1,2}$) and the air gap spacing (d).

A major issue in the fabrication of the C^3 laser is the optical alignment between the two cavities, if the air gap will be formed by cleaving. One can certainly think of using the etching technology to form the air gap, the quality of the facet; however, cannot be guaranteed unless the chemically assisted ion beam etching (CAIBE) is exploited [44]. With CAIBE, the precise control of the air gap spacing becomes difficult, especially when the required spacing is no more than a few micrometers. An elegant approach to form the C^3 laser with a narrow air gap is the microcleaving technique [45]. In this technique, after the air gap section is defined, a selective wet (chemical) etching step is applied first to remove the material (InP) surrounding the active region (InGaAsP or AlGaInAs) inside the air gap, which leaves the latter as a thin bridge hanging over in the middle. The wafer or bar is then soaked inside some liquid and placed inside an ultrasonic cleaning bath for breaking down the active region bridge inside the air gap. The facet formed by this approach has a quality equivalent to the one obtained by the conventional cleaving technique. Since the etching of the air gap won't go very deep after passing though the active region, there is no optical alignment problem as the pair of coupled cavities still sits on top of the same substrate.

Despite its readiness in fabrication [46], the C^3 structure never becomes a popular SLM laser product for its low single-mode yield and the reliability concern. The low yield comes from the sensitive phase-matching condition, which requires precise control on cavity geometrical dimensions, including both cavity lengths and the air gap spacing, as well as the effective index of the waveguide. Since the latter depends not only on the material composition and cross-sectional geometrical dimension design, but also on operating conditions such as the ambient temperature and injection current, it naturally has a very low probability to hit the stable SLM operation condition with a high SMSR over an entire bias range. The reliability concern comes from the extra pair of facets appeared in the C^3 structure, especially when it is difficult to get them protected with dielectric coating layers, for the coating is not only difficult to be applied to the narrow air gap, but also changes the lasing condition.

Figure 30.17 shows the simulated optical spectrum of a typical SLM C^3 laser, with its structural parameter given in Table 30.2, and other parameters the same as those given in Table 30.1.

30.3.3 Etched Slotted Laser

An alternative version of the coupled-cavity structure is the etched slotted SLM laser [47–50] with its typical structure shown in Figure 30.18. The main difference lies in that the coupled cavities in such structure are formed by one or multiple etched slots across the waveguide without passing through the active region. As such, there is no optical alignment issue as the coupled-cavity device still stays as a whole piece. There is no reliability concern either as no extra active region cross section is exposed other than the usual end facets. The major drawback of this structure as compared to the C^3 laser is its much reduced reflectivity (r) of the equivalent OBPF as appeared in Equation 30.39 as the general lasing condition for coupled-cavity lasers. For an individual slot, its reflectivity is given by

$$R' = (n_{\text{eff}} - n'_{\text{eff}})/(n_{\text{eff}} + n'_{\text{eff}}) \tag{30.47}$$

with n_{eff} and n'_{eff} as the effective indices of the normal section and the waveguide inside the etched slot, respectively. As compared to the normal section, the etched slot only has its waveguide cladding layer

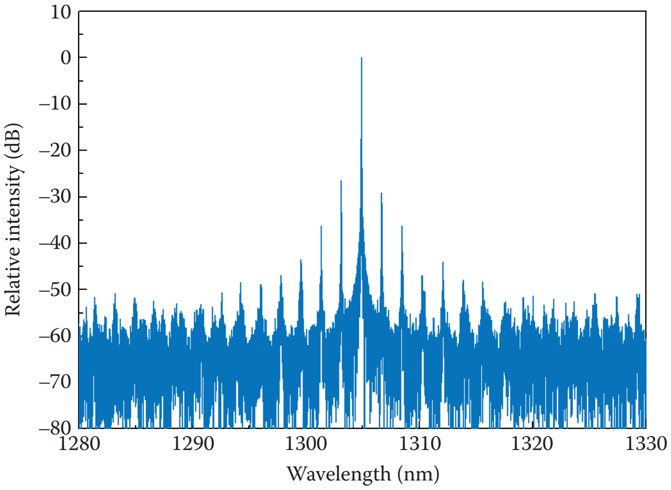

FIGURE 30.17 The simulated lasing spectrum of a typical SLM C^3 laser, with its parameters given in Table 30.2 and Table 30.1, respectively.

TABLE 30.2 C^3 Laser Parameters

Parameter	Value
Cavity lengths L_1, L_2 (μm)	136, 121 [46]
Gap between cavities d (μm)	5
Cleaved facet reflectivity r	0.565

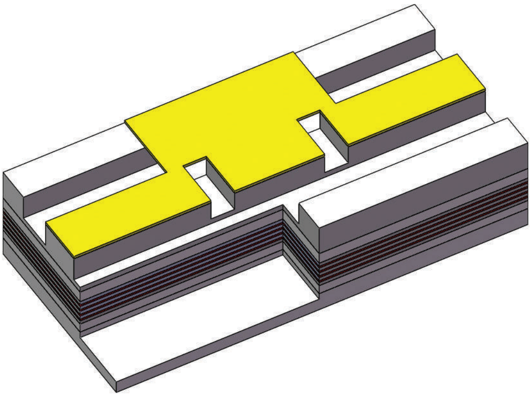

FIGURE 30.18 A typical etched slotted laser structure.

thinned to some extent, one then cannot expect a significant difference between n_{eff} and n'_{eff}. Therefore, R' given by Equation 30.47 is usually much smaller than the corresponding reflectivity in the C^3 laser given by Equation 30.43. From Equations 30.39 and 30.40, one knows that the contrast of the effective reflectivity $\bar{R}$ of the coupled-cavity laser at different wavelength will be reduce with a decreasing reflectivity R', Consequently, its ability on selecting the SLM drops significantly for the etched slotted laser.

To solve the poor mode selection problem, multiple etched slots have been introduced. A cascade of the structure in Figure 30.15 can be exploited to model such coupled-cavity laser with multiple etched slots.

A modified lasing condition similar to Equation 30.39 can also be derived with its effective reflectivity shown as a multiplication of multiple wavelength-dependent factors, with each of the factor corresponding to a single slot. As such, the wavelength spectral contrast of its effective reflectivity will be raised and its mode-selection ability will be improved. However, the multiple slotted coupled-cavity laser usually suffers an even lower single-mode yield, for the associated phase-matching condition becomes more complicated due to the introduction of multiple slots and the chance for it to be satisfied becomes rare.

30.3.4 Discrete Mode Laser

As shown in Figure 30.19, the discrete mode laser [51,52] can be viewed as a specific type of multiple slotted coupled-cavity laser with its slot's spacing properly designed to satisfy the phase-matching condition. As such, its single-mode yield can be significantly improved. With its general design rule given in Reference [52], the discrete mode laser is actually an SLM device between the grating-assisted laser and the coupled-cavity laser. It is apparent that, starting from a pair of coupled FP sections (i.e., the C^3 laser), as one increases the number of coupled FP sections with reduced reflectivities from section to section, and arranges the length of each FP section to satisfy certain phase-matching condition, one readily obtains various of grating-assisted lasers. As a special case, for a design with a uniform unit length from one FP section to another (Λ) selected to match the round trip phase-matching condition $4\pi n_{\text{eff}}\Lambda/\lambda = 2\pi$, one obtains a DFB laser with the first-order Bragg grating, as the uniform unit length design forms a periodic structure (i.e., a grating) with its periodicity (Λ) specified exactly the same as Equation 30.4, the phase-matching condition for the first-order Bragg grating. Therefore, the concept of the discrete mode laser actually bridges the grating-assisted lasers and the coupled-cavity lasers as the two main categories of SLM lasers.

30.3.5 New Aspects in Governing Equations and the Solution Technique

In general, the governing Equations 30.22 through 30.29 can still be used in modeling the coupled-cavity lasers. Since there is no grating involved, π/Λ should be replaced by $2\pi n_{\text{eff}}/\lambda$ with the grating coupling coefficients ($\kappa_{+,-}$) set to zero.

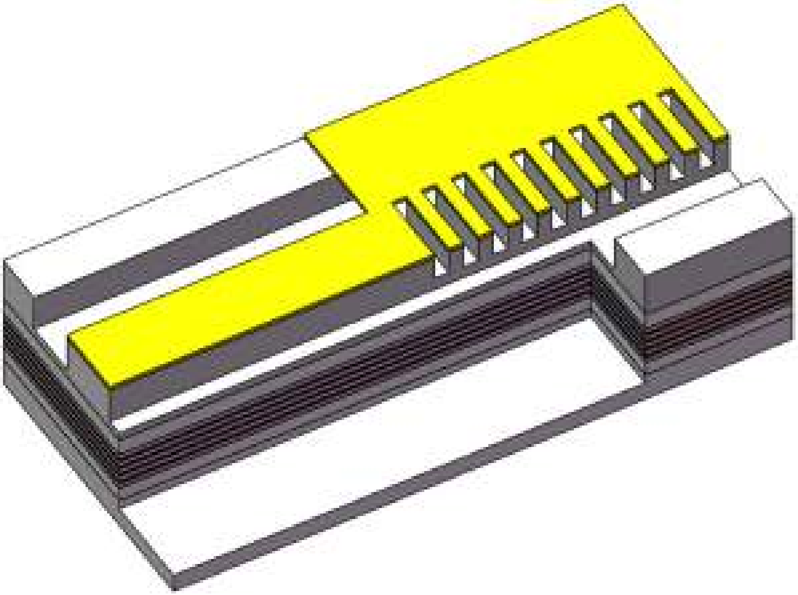

FIGURE 30.19 A typical discrete mode laser structure.

To treat the uniform sections in the coupled-cavity structure, the gain spectral dispersiveness must be considered to make sure that the lasing will happen in the neighborhood of the gain peak, as otherwise there will be no specific wavelength can be referred but the lasing cannot possibly happen at an arbitrary wavelength. Actually, the first term on the right-hand side of Equation 30.22 should be a time-domain convolution between the material gain and the field envelope, rather than be a product of them [53]. This term in its current form in Equation 30.22 is obtained under the assumption that the gain spectral bandwidth is much broader than the field envelope bandwidth, so that the time-domain gain performs as a Dirac δ-function in the convolution, which takes away the integration. For an SLM laser, the latter is usually determined by its linewidth or the modulation signal base bandwidth, whichever is broader, if the laser is under direct modulation. As the gain spectral bandwidth is usually in the range of 60 nm, whereas the field envelope bandwidth of an SLM laser usually is no more than 1 nm, the aforementioned assumption is indeed valid. To restore the gain dispersiveness in the coupled-cavity laser, however, this assumption has to be removed and a special solution technique will have to be introduced in dealing with the time-domain convolution between the material gain and the field envelope. An efficient way to treat the convolution in an initial value problem specified by a set of time-domain differential equations (or more accurately, a mixed initial-boundary value problem specified by a set of time-space domain partial differential equations) is the digital filtering method [16,54]. In this method, the material gain spectral profile is first calculated by the physics-based model within a limited wavelength range [16]. Its shape is then duplicated in the entire wavelength domain to form a periodic function, with nothing changed in its original wavelength range. The time-domain material gain can therefore found by taking the inverse Fourier transform of its spectral function. Since the latter function is turned into a periodic one, the time-domain gain therefore becomes a summation of a set of Dirac δ-functions, weighted by factors obtained as the corresponding coefficients in its Fourier expansion. Consequently, the convolution is reduced to a summation of a set of field envelopes, shifted in time domain and weighted by the said factors. For a given laser structure, these factors just need to be calculated once after the material gain spectral profile is obtained. The digital filtering method is, therefore, very efficient in handling the convolution in conjunction with the time-domain solution techniques, such as the split-step method, for solving Equation 30.22 [38,55].

Yet another problem often appearing in modeling the coupled-cavity laser is the involvement of the passive sections without injection. It is obvious that the material gain, the refractive index change, and the noise contribution in Equation 30.22 all need to be taken away for the passive sections. By noticing that Equation 30.22 become completely decoupled with the rest governing equations, one can solve these in frequency domain only for once to extract the reflectivity and transmissivity of the field envelope for these sections. In the rest (active) sections, the set of governing equations will be solved in time domain as described previously. Upon the propagating waves reach the boundary at the passive section, however, the reflected and transmitted field can be computed by taking the time-domain convolution between the incident field and the inverse Fourier transform of the reflectivity and transmissivity, respectively, as the reflectivity and transmissivity are both defined in frequency domain. Once again, the digital filtering approach can be employed in dealing with the time-domain convolution [56]. Since the reflectivity and transmissivity only need to be calculated once for a given structure, the convolution handled in such a way is very efficient. Generally, the mixed domain method, i.e., treating Equation 30.22 in time domain for active sections and in frequency domain for passive sections, is much more efficient compared with the full time-domain method, especially for passive units with long section lengths, because the frequency-domain treatment links the input and output fields of the passive section directly through transfer functions (i.e., the reflectivity and transmissivity, respectively) in a single step, without any step-by-step marching along the wave propagating direction as required by time-domain approaches.

30.3.6 Performance Comparisons among Coupled-Cavity SLM Lasers

The simulated performance of a few different types coupled-cavity SLM lasers is summarized in Table 30.3. A general tendency is that as the SMSR increases with the number of slots (i.e., the number of coupled

TABLE 30.3 Performance Comparison among Different Coupled-Cavity SLM Lasers

Laser Structure	SMSR (dB)	SLM Yield (SMSR> 15 dB)	SLM Yield (SMSR> 25 dB)
C^3 laser	12–32	60%	20%
Etched slotted laser (2 slots)	6–19	27%	0%
Discrete mode laser (5 slots)	11–29	73%	13%
Discrete mode laser (9 slots)	9–36	60%	40%
Discrete mode laser (19 slots)	7–49 (42, measured value in [52])	47%	33%

Note: The experimentally measured SMSR for a discrete mode laser with 19 slots is given in the brackets.

cavities), the SLM yield decreases. This result agrees with our conclusion drawn by the general OBPF model for the coupled-cavity structures, since the increased slot number enhances the wavelength spectral contrast of the effective reflectivity, thereby enhances the structure's mode selection ability, whereas it simultaneously introduces a more complicated phase-matching condition that is increasingly difficult to be satisfied.

30.4 Recent Development on Single Longitudinal Mode Laser Diode

30.4.1 Open Problems in SLM Lasers

Current SLM lasers are not yet ideal. Grating-assisted lasers generally suffer problems like high fabrication cost and highly sensitive to external feedback. The DBR laser needs the technology to monolithically integrate the active region with the passive grating section in different material compositions. The uniform-grating purely refractive index-coupled DFB laser has a relatively low single-mode yield, whereas the QWPS DFB laser has even poorer immunity to external feedback and wastes half of its output power, and complex-coupled DFB lasers usually have reliability issues. A variety of the grating-assisted laser structures have been proposed, but all as compromised approaches with none of them seeming to be able to solve all the aforementioned problems. Coupled-cavity lasers usually have low fabrication cost and less sensitive to external feedback. However, they all have low single-mode yield and suffer relatively low SMSR. Therefore, it still remains as an open problem on how to obtain reliable SLM lasers with high single-mode yield, high SMSR, high immunity to external feedback, and low fabrication cost.

In the past decade, some progress has been made toward the final solving of the remaining problems in SLM lasers, although most of the recent efforts on laser development have their targets on new applications found in data communication systems and telecommunication access networks with emphases on multiple wavelength accessibility and tunability, and high-speed direct modulation. Effort has also been put on developing SLM lasers with narrow linewidth to meet the strong demand in high-speed long-haul coherent telecommunication systems in advanced modulation-detection schemes with higher spectral efficiency. A thorough description on all these new developments is beyond the scope of this chapter, so that we will only give a brief introduction on the new structures that are closely relevant to SLM lasers.

30.4.2 Bragg Waveguide SLM Laser

A schematic structure of the Bragg waveguide SLM laser [57,58] is shown in Figure 30.20. Unlike the conventional SLM lasers that all utilize their cavity structure to select the single lasing mode, this structure exploits the waveguide itself to eliminate the unwanted modes in an FP cavity.

The working principle of the Bragg waveguide can be understood by a simplified model described in Figure 30.21. By exploiting the effective index method, one reduces the wave vector of an arbitrary plane traveling wave into a two-dimensional plane as shown in Figure 30.21. It can then be decomposed into a pair of orthogonal components, with the one along the waveguide direction (β) as the required wave

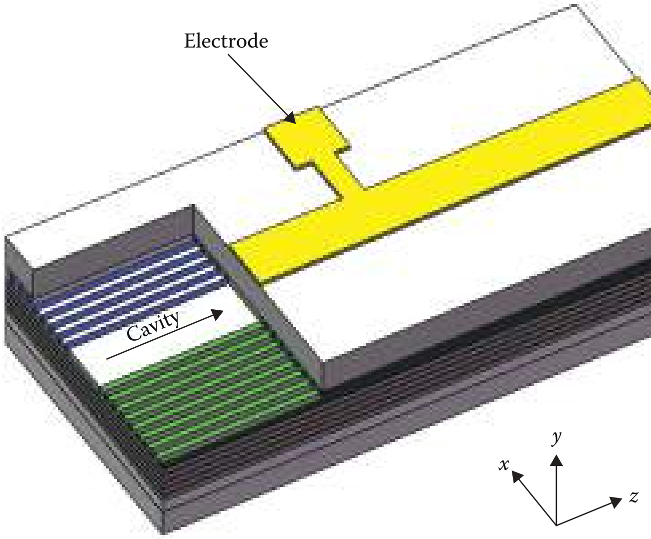

FIGURE 30.20 The Bragg waveguide SLM laser structure.

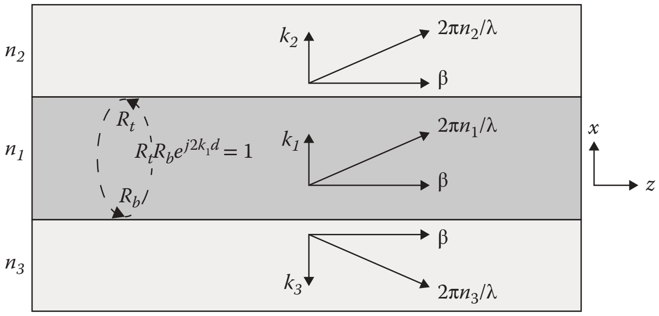

FIGURE 30.21 An illustrative diagram showing the concept of the dielectric waveguide, with $2\pi n_{1,2,3}/\lambda$ indicating the conceptual free-propagating plane wave numbers inside the core, the top cladding, and the bottom cladding layer, respectively, β their corresponding wave vectors' projection along the propagation (z) direction, $k_{1,2,3}$ their corresponding wave vectors' projections along the cross (x) direction in the core, the top cladding, and the bottom cladding layer, respectively, $R_{t,b}$ the amplitude reflectivities between the core and the top cladding layer, and between the core and the bottom cladding layer, respectively; $R_tR_be^{j2k_1d} = 1$ gives the resonance condition along the cross direction with d as the core layer thickness, which stands as the necessary and sufficient condition for guided waves in general waveguides.

propagation constant, the other along the cross direction (k_1) as the wave vector needs to be confined. For the wave component that propagates in the cross direction, a round trip travel would make the initial field E_0 become $E_0R_tR_be^{j2k_1d}$, with $R_{t,b}$ denoting the amplitude reflectivity between the core and the top cladding layer, and the core and the bottom cladding layer, respectively, and d the core layer thickness. Therefore, once the resonance happens in the cross direction, i.e.,

$$R_tR_be^{j2k_1d} = 1 \tag{30.48}$$

the field distribution along the cross direction remains the same at any cut along the waveguide direction, which means the wave is guided and propagates with β along the waveguide. This is actually a necessary and sufficient condition for a general waveguide, i.e., if and only if the wave resonates in the cross section, it will be guided by the waveguide. Consequently, the guided wave will form a standing wave pattern inside the core area of the waveguide, and will be either zero (for metallic waveguide) or evanescent (for dielectric waveguide) outside of the core. The guided wave's cross-sectional distribution doesn't change as the wave propagates along the waveguide. The only change on the wave as it propagates is its phase, scaled by $\beta z - \omega t$, with z and t indicating the space coordinate along the waveguide (i.e., in the wave propagation direction) and the time variable, respectively.

For the conventional dielectric waveguide that utilizes the total internal reflection effect, one finds that

$$k_{1,2,3} = \sqrt{n_{1,2,3}^2(2\pi/\lambda)^2 - \beta^2} \tag{30.49}$$

for the wave vector components along the cross direction in the core (with subscript 1), the top cladding (with subscript 2), and the bottom cladding (with subscript 3) layer, respectively, with $n_{1,2,3}$ denoting the refractive indices of these three layers. The propagation constant β, i.e., the wave vector component along the propagation direction (z), must be the same for the same guided wave distributed in different layers, as otherwise the guided wave would be split apart along with its propagating in z. Under the total internal reflection scheme, the refractive indices are chosen in such a way to make k_1 real ($2\pi n_1/\lambda > \beta$) but $k_{2,3}$ imaginary ($2\pi n_{2,3}/\lambda < \beta$). By noticing that $R_{t,b} = (k_1 - k_{2,3})/(k_1 + k_{2,3})$ for the TE wave with its electric field polarized in parallel with, and $R_{t,b} = (1/k_1 - 1/k_{2,3})/(1/k_1 + 1/k_{2,3})$ for the TM wave with its electric field polarized perpendicularly to, the boundary between different layers, respectively, one has $|R_{t,b}| = 1$ as the reflectivity at the boundary always takes the form of $(a - jb)/(a + jb)$. Consequently, the resonant condition (Equation 30.48) in the cross direction is reduced to

$$\varphi_t + \varphi_b + 2k_1 d = 2m\pi \tag{30.50}$$

with $\varphi_{t,b}$ indicating the phase of $R_{t,b}$, i.e.,

$$\varphi_{t,b} = -2\arctan(|k_{2,3}|/k_1) \tag{30.51}$$

for the TE wave and

$$\varphi_{t,b} = -2\arctan(k_1/|k_{2,3}|) \tag{30.52}$$

for the TM wave, respectively. Equations 30.49 through 30.51 or Equation 30.52 defines the dispersion relation of the guided wave, which tells that, for a given waveguide structure and operating wavelength λ below a maximum value known as the cutoff wavelength, one always manage to find at least one real β within the range between $2\pi\max(n_2, n_3)/\lambda$ and $2\pi n_1/\lambda$ as the solution. Therefore, the conventional dielectric waveguide has no wavelength selection ability as the dispersion relation of its guided wave shows a high-pass filter feature that supports the wave propagation with any wavelength shorter than the cutoff value, which also echoes the same statement we made at the beginning of this chapter. It is not surprising for one to reach this conclusion, once one notices that as the total internal reflection condition is satisfied, $|R_t R_b|$ is always 1 regardless of the associated wavelength. The cross-directional resonant condition, as the indication of the wave being guided, is therefore reduced to a phase-matching condition (i.e., the dispersion relation) that is too loose to select a discrete set of wavelengths, not to mention a single wavelength.

If, however, a grating-based reflection is utilized to substitute the total internal reflection, as shown in the structure given by Figure 30.20, it will be possible to make $R_t R_b$ wavelength dependent. Once not only the phase-matching condition in the form of Equation 30.50, but also a wavelength-dependent amplitude condition in the form of $|R_t(\lambda)R_b(\lambda)| = 1$, will jointly be derived from the general resonant condition

(Equation 30.48), it is possible that only a single wavelength can be found for the guided wave to satisfy both constraints imposed on the phase and amplitude.

The Bragg waveguide laser is such a device that exploits the grating reflection, rather than the total internal reflection, in its waveguide in conjunction with the FP cavity to reach the SLM operation. With a structure similar to the DBR laser arranged in the cross direction perpendicular to the waveguide for wave confinement, even a simple FP cavity makes an SLM laser [58]. A unique feature of the Bragg waveguide lies in that it allows its core layer to have a lower refractive index than that of its cladding. As such, the selection on the gain medium to build the active region for the Bragg waveguide laser will be more flexible.

30.4.3 Double-Trench Resonant Tunneling SLM Laser

As concluded by Section 30.3, the concept of the coupled cavity can generally be understood as the insertion of an OBPF into a conventional FP cavity, for purifying the lasing spectrum by eliminating all unwanted FP cavity modes. An accompanying issue is that both the transmitted light passed through the OBPF and the reflected light experienced the complementary optical band-reject filter (OBRF) stay inside the FP cavity, which add up to give no appreciable mode selection mechanism once their gains are the same, since the added spectrum of the complementary OBPF and OBRF turns out to be flat. Although the additionally introduced phase condition by the equivalent filter and any possible gain discrimination between the transmitted and reflected waves will help to eliminate the unwanted FP cavity modes, the single-mode yield and SMSR for such structures are usually low. And the SLM lasing is usually not very stable in the entire laser operating range. For example, the lasing mode often hops or the SMSR deteriorates as the bias current or ambient temperature changes. This can be attributed to the phase-sensitive lasing condition shown as Equation 30.33 or Equation 30.39, since the phase not only varies with any geometrical dimension deviation of the structure in the fabrication process, but also changes with the laser operating condition.

To ensure the SLM operation with an intensified SMSR with high yield, one needs to effectively eliminate the reflected light from the aforementioned OBPF inside the FP cavity. As shown in Figure 30.22, a double-trench structure has been proposed [59] to introduce dual reflections that cancel out the reflected light at a specific wavelength determined by the gap between the two trenches, an effect known as the resonant tunneling. As such, the transmission spectrum of the double trenches resembles that of an OBPF, which selects one of the many cavity modes in a conventional FP laser for single-mode operation. The most important design in this structure, which significantly improves the SLM laser performance, is to make the double trenches slanted so that the reflected waves with unselected wavelengths by the OBPF will escape

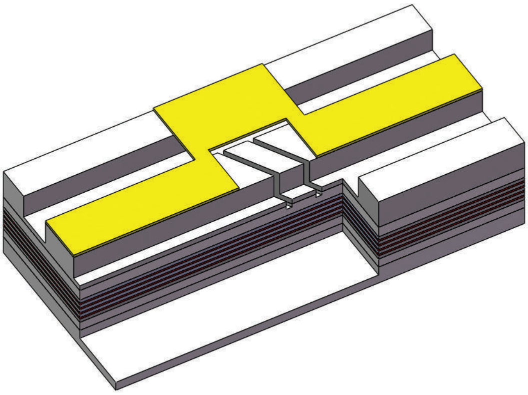

FIGURE 30.22 The double-trench resonant tunneling SLM laser structure.

from the cavity, in order to avoid jeopardizing the single-mode lasing condition, as otherwise the reflected and transmitted light in different wavelengths will compete to each other inside the cavity.

By eliminating the reflection brought in by the OBPF made of the double trenches, i.e., by letting $r_{12}, r_{21} \sim 0$, $\delta = t_{12}t_{21}$, the lasing condition (Equation 30.33) derived for general coupled-cavity lasers reduces to

$$t_{12}t_{21}R^2e^{2j(\varphi_2+\varphi_1)} = 1 \tag{30.53}$$

which indicates that the lasing will be determined by the transmission spectrum of the inserted OBPF. More specifically, the lasing will happen at the wavelength in the neighborhood of the transmission spectrum ($|t_{12}t_{21}|$) peak. Actually, once the transmission spectrum of the filter resembles that of an OBPF, the lasing condition shown in Equation 30.53 is the same as that of the DBR laser (Equation 30.13).

The simulated and measured lasing spectrum and SLM yield of a typical double-trench resonant tunneling SLM laser are given in Figures 30.23 and 30.24, respectively. The simulation result also shows, and experimental data verifies that, with varying positions of the double trenches inside the FP cavity, the slanted trench pair can always select and lock in one and only one of the many FP modes in the full laser operating range [59]. This can be attributed to the fact that, with the reflection from the double trenches effectively eliminated and consequently with the lasing condition determined by Equation 30.53 rather than Equation 30.33 or Equation 30.39 for the device, its mode selection mechanism is no longer phase sensitive. Hence the precise control of the geometrical dimension in the structure is not required in the fabrication process for such a device, which greatly enhances the single-mode yield, the SMSR, and the single-mode stability in operation, as compared to other existing coupled-cavity lasers.

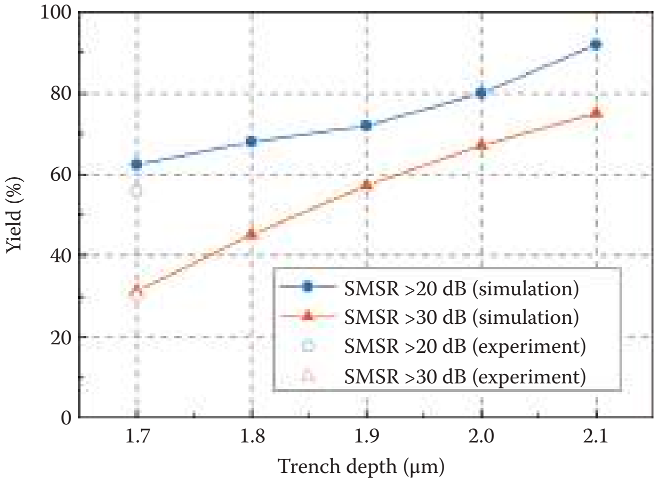

FIGURE 30.24 The SLM yield as a function of the trench depth, with device design parameters given in Reference [59].

30.4.4 Horn Ridge Waveguide (HRW) DFB Laser

With its structure shown in Figure 30.25, the horn ridge waveguide (HRW) DFB laser [60] improves the single-mode yield by breaking the inherent dual-mode degeneracy in the uniform-grating purely refractive index-coupled structure.

In a straight-waveguide purely refractive index-coupled DFB laser with uniform grating, the two longitudinal modes with their respective wavelengths located at each side of the Bragg stopband have the same reflection everywhere along the cavity due to the symmetry in the reflection spectrum, so that they have the degenerated field distribution. The longitudinal modes at the two wavelengths with the degenerated field distribution will then have the same modal gain, which causes either dual-mode operation or SLM lasing with poor SMSR if the degeneracy is somehow removed by the uncontrollable LSHB effect. In the HRW DFB laser, however, an effective chirp to the uniform grating is introduced. As such, the field of the longitudinal mode with the wavelength on the blue side will concentrate in the right section with the wider ridge width, as a consequence of the strong reflection it sees from the left section with the narrow ridge width, where the local Bragg wavelength takes a relative shift toward the shorter wavelength side due to the reduction on the local effective index. On the contrary, the field of the longitudinal mode with the wavelength on the red side will concentrate in the left section with the narrower ridge width, as a consequence of the strong reflection it sees from the right section with the wider ridge width, where the local Bragg wavelength shifts relatively toward the longer wavelength side due to the enhancement on the local effective index. Therefore, the major effect of the effectively chirped grating is to remove the degeneracy of field distributions of the two symmetrical modes on each sides of the Bragg stopband. With the help of such effectively chirped grating, the two longitudinal modes at the Bragg stop-band will take different distributions and have their associated field intensities spatially localized in different sections along the cavity. With the further help of the nonuniform modal gain simultaneously generated by the horn waveguide, the field distribution having a larger overlap with the modal gain turns out to be the only dominant lasing mode. In this particular structure, the modal gain is higher on the wide ridge side due to the larger confinement factor associated. Hence the wavelength at the blue side of the Bragg stop-band, i.e., the shorter wavelength, will be selected to lase, whereas the wavelength at the red side, i.e., the longer wavelength, will be effectively suppressed.

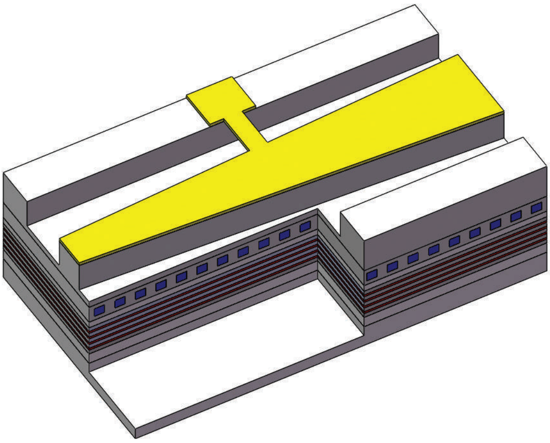

FIGURE 30.25 The horn ridge waveguide (HRW) DFB laser structure.

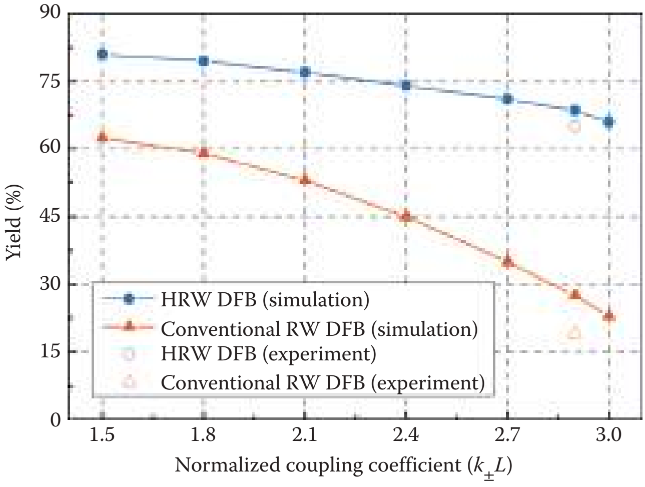

FIGURE 30.26 Comparison on the SLM yield (SMSR >30 dB) between the HRW DFB and the conventional ridge waveguide (RW) DFB with different κ ± *L*; other device design parameters are given in Reference [60].

Simulation result shows, and experimental result demonstrates, that the SLM yield can be drastically raised (by more than threefolds) with an optimized HRW design, especially for the uniform-grating purely refractive index-coupled DFB laser with high normalized coupling coefficient (κ*L*) [60]. This is further evidenced by the comparison result in Figure 30.26. Finally, measured lasing spectra of a typical HRW DFB laser under different bias current are shown in Figure 30.27.

Acknowledgment

The author would like to express his sincere thankfulness to Cheng Ke for his great help on performing most of the numerical calculations and on drawing all the figures.

31.1 Introduction

Semiconductor lasers, and a narrow waveguide edge-emitting semiconductor lasers, in particular, are attractive devices for different applications. Among others, these are high-speed all-optical signal processing, optical data storage, thermal and xerographic printing, scanning, directional lighting, secure communications, random number generation, frequency conversion, or various interferometric, spectroscopic, instrumentation, and other quantum-optical experiments.

A typical solitary narrow waveguide (single transversal mode) semiconductor laser exhibits a single-wavelength emission required in different applications. In many cases, however, small fluctuations of the operation conditions impose a significant phase noise which, in turn, causes an unwanted broadening of the emission linewidth. Moreover, the stable performance of the laser can be easily violated by optically reinjected light, and there is a huge number of studies devoted to the analysis of the nonlinear dynamics in lasers with a delayed optical feedback.

A properly designed optical feedback, however, can also play a constructive role when seeking to improve an operation of the solitary laser, or create a new dynamical regime. For example, an external cavity with a diffractive grating can be used for emission linewidth reduction or tuning of the lasing wavelength

[1]. Or, on the contrary, specially designed external cavities allow realizing a chaotic emission usable for cryptography [2] or random number generation [3].

Multisection semiconductor lasers (MSLs) in linear or ring configurations and coupled laser devices provide even more possibilities to tailor laser dynamics for certain applications. For example, a variety of important functionalities of the optical data communications [4], such as pulse generation, clock recovery, and fast switching can be realized by specially designed and differently interconnected MSLs. Several examples of theoretically investigated and experimentally verified dynamic performance of MSLs considered in our previous works are excitability [5], high-frequency mode-beating pulsations [6], and modulation band enhancement [7] in distributed feedback (DFB) lasers with an integrated passive phase tuning section (passive feedback lasers); passive [8] or hybrid [9] harmonic and sub-harmonic mode-locking in lasers with saturable absorber, and pulse broadening in quantum dot (QD) mode-locked lasers [10]; tunable high-frequency pulsations in the detuned grating DFB lasers with an integrated phase tuning section (phase controlled mode-beating lasers) [11,12]; stationary, pulsating, and irregular regimes and their bifurcations in DFB lasers with integrated phase tuning and amplifying sections (active feedback laser) [6,13]; Joule heating–induced transitions between steady states in distributed Bragg reflector (DBR) lasers [14] or external cavity diode lasers (ECDLs) [15].

All these examples confirm the practical importance of modeling, simulations, and analysis of MSLs for designing new devices with a particular dynamical behavior. The most precise models usually are given by 2+1 or 3+1 dimensional systems of partial differential equations (PDEs) [16,17]. The numerical simulations in this case, however, are time consuming, whereas application of analytic methods for the analysis of the nonlinear dynamics is very limited. Unfortunately, numerical simulations of such models are time consuming, whereas an application of analytic methods for the model analysis is very limited. For this reason, we prefer to use simpler approaches which, may be, fail to reproduce a quantitative-, but still allow to get a qualitative agreement between theory and experiments.

For some MSLs, already simple ordinary differential equation (ODE) or delay differential equation (DDE) systems (rate equations) admit a reasonable description of the laser dynamics. An advantage of these models is their simplicity allowing fast numerical simulations and application of advanced analytic methods, such as asymptotic analysis, stability analysis, or numerical continuation and bifurcation analysis. These models, however, usually are based on mean-field approximations, i.e., neglect inhomogeneity of laser parameters and dynamical variables along the laser cavity, take into account only a few fundamental characteristics of the considered lasers, or are suited to describe particular MSL configurations [18–20].

The 1+1-dimensional traveling wave (TW) model considered in this chapter is a compromise between simplicity and precision. It is a first-order PDE system having a single spatial dimension corresponding to the longitudinal (z-) direction along the laser cavity and describing dynamics of the slowly varying optical field amplitudes, polarization functions, and carrier density [21–23]. Comparing to ODE and DDE models mentioned earlier, the TW model is computationally more demanding but still enables an advanced analysis, which is hardly possible in the case of the multidimensional PDE models.

By taking into account or neglecting different physical effects, one can derive a whole hierarchy of TW models of different complexities. The standard part of all such models is a pair of TW equations governing the evolution of the complex forward- and back- propagating field amplitudes, $E^{+}(z,t)$ and $E^{-}(z,t)$. These equations originate from the decomposition of the dominant fundamental transverse electric (TE) component of the electromagnetic wave,

$$E(\mathbf{r},t) = \Phi(x,y)\left[E^{+}(z,t)e^{-ik_0 z} + E^{-}(z,t)e^{ik_0 z}\right]e^{i\omega_0 t}.$$

Here, ω_0 is the central reference frequency and k_0 the corresponding wave vector. Whereas the transversal waveguide mode profile, $\Phi(x,y)$, is an eigensolution of the waveguide equation, the related complex eigenvalue of the same problem defines the propagation factor β [24], which determines the evolution of the field amplitudes $E^{\pm}$. In general, the propagation factor depends on the complex interaction of carriers and photons. In our modeling approach, we apply a phenomenological dependence of this factor on the real carrier

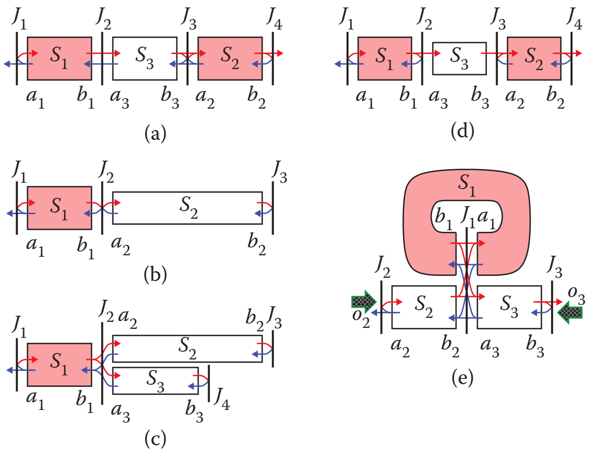

FIGURE 31.1 Schematic representation of five semiconductor laser devices, which can be considered by our modeling approach: (a) three-section laser, (b) laser with a trivial external cavity, (c) laser with a dual external cavity, (d) master–slave laser system, (e) optically injected ring laser with an outcoupling waveguide. Shaded and white frames represent active and passive *sections* (S_*) of the MSL. Thick black segments and thick hatched arrows indicate *junctions* (interfaces of these sections, J_*) and *optical injections* (o_*), respectively. Thin arrows show optical field transmissions and reflections at the interfaces of the laser sections.

density function N, which can represent dynamics of the spatially distributed carrier density, $N(z, t)$, or the section-wise averaged density, $N(t)$. The evolution of N itself is governed by a single or several rate equations.

One can use the TW modeling approach for consideration of various differently interconnected linear and curved, active and passive semiconductor waveguiding parts, taking into account optical injections, field reflections, and transmissions at the interfaces of different laser parts, as well as delayed feedback of the optical fields from the external cavities. For simulation and analysis of the MSLs, we apply our software LDSL-tool [25], which is suited to investigate the longitudinal dynamics of multisection semiconductor lasers. This software allows considering a large variety of MSL devices or coupled laser systems which can be represented by a set of mutually interconnected *sections* and *junctions*, see the schematic representations of several laser devices in Figure 31.1. Besides of numerical integration, LDSL-tool can find longitudinal optical modes and analyze their dynamics [23,26]. In some cases, it locates stable and unstable stationary states of the system [15,27], constructs the reduced ODE models based on a finite number of the optical modes [28], and, together with the software package AUTO [29], performs numerical continuation and bifurcation analysis of these reduced models [7].

In following, we shall introduce a basic TW model for the solitary laser, and present several model extensions allowing to take into account initially neglected physical effects. Next, we shall discuss a possibility to join several laser sections into a single multisection laser or a coupled laser device. For an illustration of the available device complexity, we shall present simulations of a ring laser with four branches of filtered feedback. At the last part of this chapter, we shall briefly introduce the concept of the instantaneous optical modes, discuss the mode analysis, the location and semi analytic continuation of the stationary states, the model reduction, and the numerical bifurcation analysis.

31.2 Basic TW Model in the Solitary Laser

In this section, we formulate the simplest TW model suitable for simulations of a solitary semiconductor laser. Let us consider an edge-emitting narrow-waveguide semiconductor laser (see Figure 31.2a). According to our notations, the "interior" part of this laser is referred as *section* S_1. The longitudinal coordinates

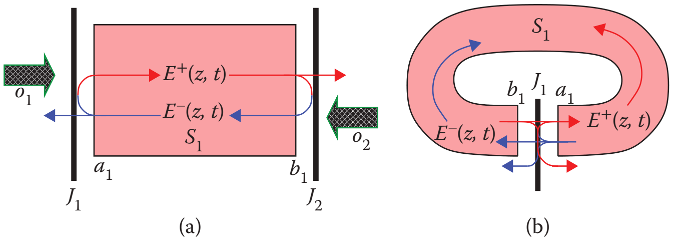

FIGURE 31.2 Schematic representation of the single section lasers in (a) linear and (b) ring configurations. Thin arrows indicate directions of the counter-propagating fields and their reflections/transmissions at the laser facets [J_1 and J_2, panel (a)] or point outcoupling interface [J_1, panel (b)]. Thick hatched arrows represent optically injected fields.

of the section edges and the length of this section are $z = a_1$, $z = b_1$, and $|S_1| = b_1 - a_1$, respectively. The front and the rear laser facets (*junctions* J_1 and J_2), in this case, correspond to the left and the right edges a_1 and b_1 of S_1.

The backbone of the TW model of this laser is the linear system of partial differential (TW) equations describing an evolution of the slowly varying complex amplitudes $E^+(z, t)$ and $E^-(z, t)$ of the counter-propagating optical fields:

$$\begin{cases} \frac{n_g}{c_0}\partial_t E^+ + \partial_z E^+ = -i\beta E^+ - i\kappa E^- + F_{sp}^+ \\ \frac{n_g}{c_0}\partial_t E^- - \partial_z E^- = -i\beta E^- - i\kappa E^+ + F_{sp}^- \end{cases}, \quad z \in S_1. \tag{31.1}$$

Here, c_0 is the speed of light in vacuum, $F_{sp}^{\pm}$ are the Langevin noise source contributions to the optical fields, and n_g is the group velocity index. The real and the imaginary parts of the complex coefficient κ represent the distributed index and gain/loss coupling of the counter-propagating fields, respectively. κ is nonvanishing in the laser sections containing Bragg grating and is set to zero in the straight sections without the grating. Without an additional scaling of the field functions $E^{\pm}$, $|E(z, t)|^2 = (E, E) = |E^+|^2 + |E^-|^2$ represents the photon density and is proportional to the local field power,

$$\mathcal{P}(z, t) = \frac{\sigma c_0}{n_g} \frac{hc_0}{\lambda_0} |E(z, t)|^2.$$

Here, σ is the cross-section area of the active zone, λ_0 the central wavelength, and h the Planck constant.

Active Sections:

The propagation factor β in the TW equations above can be defined as

$$\beta = \delta_0 + \tilde{n}(N) + \frac{i(g(N) - \alpha)}{2}, \tag{31.2}$$

where the peak gain and refractive index change functions $g(N)$ and $\tilde{n}(N)$ are given by the simple linear relations

$$g(N) = \Gamma g' \left(N - N_{tr}\right), \qquad \tilde{n}(N) = \frac{\alpha_H g(N)}{2}. \tag{31.3}$$

Here, N is the carrier density. The parameters δ_0, α, Γ, g', and α_H are the internal field loss, the initial fixed detuning from the central frequency, the confinement factor, the differential gain, and the linewidth enhancement (Henry) factor evaluated at the transparency carrier density N_{tr}, respectively.

To define the evolution of the spatially averaged carrier density $N(t)$, we use a single rate equation

$$\frac{\mathrm{d}}{\mathrm{dt}}N = \frac{I}{q\sigma|S_1|} - \mathcal{R}(N) - \mathcal{S}(N, E^{\pm}). \tag{31.4}$$

Here, q is the electron charge, I is the injected current into the active zone of the section, whereas $\mathcal{R}$ and $\mathcal{S}$ are spontaneous and stimulated recombination functions, respectively. We use a cubic spontaneous recombination function,

$$\mathcal{R}(N) = AN + BN^2 + CN^3, \tag{31.5}$$

which can be simplified by assuming vanishing recombination parameters B and C and defining $A = \tau_N^{-1}$, where τ_N denotes the carrier lifetime. Function $\mathcal{S}$ in the carrier rate equation 31.4 represents the spatially averaged stimulated recombination:

$$\mathcal{S}(N, E^{\pm}) = \frac{c_0}{n_\mathrm{g}} g(N) \|E\|_1^2. \tag{31.6}$$

Here, $\|E\|_1^2$ is the spatial average of the local photon density along the section S_1,

$$\|E\|_1^2 = \langle (E, E) \rangle_1, \qquad \langle \eta \rangle_1 = \frac{1}{|S_1|} \int_{S_1} \eta(z) \mathrm{d}z, \qquad (\zeta, \xi) = \zeta^{+*}\xi^{+} + \zeta^{-*}\xi^{-},$$

and * denotes the complex conjugate.

To complete the system, we still need to define the incident forward- and backward-propagating fields at the section edges $z = a_1$ and $z = b_1$, respectively. For the solitary laser, these incident fields can be defined by the following reflection/transmission conditions:

$$E^{+}(a_1, t) = -r_1^* E^{-}(a_1, t) + o_1(t), \;\; E^{-}(b_1, t) = r_2 E^{+}(b_1, t) + o_2(t). \tag{31.7}$$

Here, r_1 and r_2 are the complex field amplitude reflectivity coefficients at the laser facets (junctions J_1 and J_2), whereas complex functions $o_{1,2}(t)$ represent optical injections at these junctions.

One can also use Equations 31.1 through 31.6 for simulations of narrow-waveguide semiconductor ring lasers with the field in- and out-coupling concentrated in the single point of this laser. Figure 31.2b shows a schematic representation of such single-section ring laser device. According to this scheme, we assume that both, "left" and "right" edges a_1 and b_1 of the section S_1, are connected at the single junction J_1. The boundary conditions (Equation 31.7), in this case, should be replaced by the following field transmission-reflection conditions at J_1:

$$E^{+}(a_1, t) = t_1 E^{+}(b_1, t) - r_1^* E^{-}(a_1, t), \;\; E^{-}(b_1, t) = t_1 E^{-}(a_1, t) + r_1 E^{+}(b_1, t). \tag{31.8}$$

Here, t_1 is the real field amplitude transmission factor back into the ring section S_1 at the outcoupling point J_1, whereas the complex factor r_1 represents the localized field backscattering at J_1.

To perform simulations of the basic TW model determined by Equations 31.1 through 31.6 and 31.7 or 31.8, one still needs to choose some initial conditions $E^{\pm}(z, 0)$ and $N(0)$. For the first run of simulations, one can use any small distribution of the optical fields $E^{\pm}(z, 0)$ and a small positive value of $N(0)$. After some transient, the computed trajectory will be attracted by one of the few regular or irregular attractors of the considered dissipative system. To keep tracing the same attractor during the following parameter continuation calculations, one should better use previously obtained carrier density and field distributions.

Passive Sections:

It is noteworthy that one can also use the TW equations 31.1 for a description of the field propagation in the passive sections, such as gratings, free space between the laser and the external mirror, etc. Here, carriers are absent, do not couple to the emission wavelength (the material gain band of these sections does not support the lasing frequencies), or are just kept at transparency level by an appropriately adjusted bias current. In all such cases, $g(N) = \tilde{n}(N) = 0$, the carrier rate equations 31.4 are decoupled from the field equations 31.1 and, therefore, are irrelevant.

In the case of the passive section S_k containing no grating ($\kappa = 0$), simple analytic relations of the field function values on the both sides of S_k,

$$\begin{gathered} E^+(b_k, t) = \eta e^{i\varphi/2} E^+(a_k, t - \tau_k), \quad E^-(a_k, t) = \eta e^{i\varphi/2} E^-(b_k, t - \tau_k), \quad \text{where} \\ \tau_k = \frac{|S_k| n_g}{c_0}, \quad \eta = e^{-\alpha |S_k|/2}, \quad \varphi' = -2\delta_0 |S_k|, \end{gathered} \tag{31.9}$$

can replace the field equations 31.1.

In the case of the passive grating ($\kappa \neq 0$), the analytic solution of the field equations 31.1 in the frequency domain is given by the 2×2-dimensional transfer matrix M [23,26,28],

$$\hat{E}(z, \omega) = M(\beta, \kappa, \omega; z, a_k) \hat{E}(a_k, \omega). \tag{31.10}$$

Here, $\beta = \delta_0 - i\alpha/2$, ω is the relative frequency, $\hat{E}(z, \omega) = \left(\hat{E}^+, \hat{E}^-\right)^T$, T denotes the transpose vector, whereas $\hat{E}^\pm$ are the frequency domain representations of the fields $E^\pm(z, t)$. Within any interval $[z', z]$ where parameters β and κ are constant, the matrix M is defined by

$$\begin{gathered} M(\beta, \kappa, \omega; z, z') = \begin{pmatrix} \cos \eta(z - z') - \frac{i\mathcal{B}}{\eta} \sin \eta(z - z') & -\frac{i\kappa}{\eta} \sin \eta(z - z') \\ \frac{i\kappa}{\eta} \sin \eta(z - z') & \cos \eta(z - z') + \frac{i\mathcal{B}}{\eta} \sin \eta(z - z') \end{pmatrix}, \\ \mathcal{B}(\omega) = \beta + \frac{\omega n_g}{c_0}, \qquad \eta = \sqrt{\mathcal{B}^2 - \kappa^2}. \end{gathered} \tag{31.11}$$

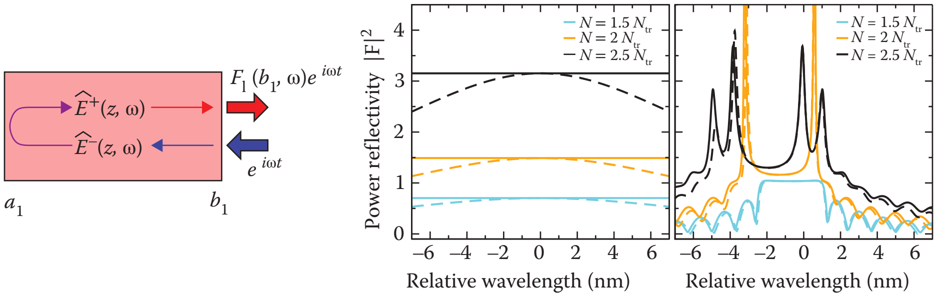
Once the parameters β or κ are peacewise constants, i.e., constant within each small subinterval $[z_s, z_{s-1}]$, $z' = z_0 < z_1 < \cdots < z_n = z$, the transfer matrix M is the superposition of the corresponding transfer matrices over these small subintervals:

$$M(\beta, \kappa, \omega; z, z') = M_n \times \cdots \times M_1, \quad M_s = M(\beta(z_{s-1/2}), \kappa(z_{s-1/2}), \omega; z_s, z_{s-1}). \tag{31.12}$$

31.3 Model of Material Gain Dispersion

The relations (Equation 31.3) introduced in Section 31.2 are simple linear approximations of the gain and refractive index functions G and $\tilde{N}$. In general, these functions depend not only on the carrier density N, but also on the optical frequency ω, field intensities $|E^+|^2$ and $|E^-|^2$, and some other physical effects, such as temperature, not considered in our modeling approach. In this section, we introduce the model of the gain dispersion of the semiconductor material, which restricts the gain band in the frequency domain and is the primary optical frequency selection mechanism in Fabry–Pérot (FP) lasers.

Before switching to the modeling of the gain dispersion, let us find out the expression of the laser response $F_l(b_1, \omega)$ to the incident plane wave $e^{i\omega t}$ applied to the right edge of the device (see Figure 31.3a). For this reason, we freeze the propagation factor β and substitute the ansatz $E^\pm(z, t) = \hat{E}^\pm(z, \omega) e^{i\omega t}$ into



(a) (b) (c)

FIGURE 31.3 Laser response to the incident plane wave $e^{i\omega t}$. (a) Schematic representation: thin and thick arrows show field propagation directions and incident/emitted optical fields. (b) Response intensity of the solitary FP laser: parameters $\lambda_0 = 1.57\,\mu\text{m}$, $|S_1| = 0.25\,\text{mm}$, $n_g = 3.6$, $\delta_0 = 0$, $\alpha = 20\,\text{cm}^{-1}$, $\alpha_H = -4$, $\Gamma = 0.15$, $g' = 4 \cdot 10^{-16}\,\text{cm}^2$, $N_{tr} = 10^{18}\,\text{cm}^{-3}$, $r_1 = r_2 = \sqrt{0.3}$, $\kappa = 0$. (c) Response intensity of the solitary DFB laser: parameters are the same as in (b), only $\kappa = 130\,\text{cm}^{-1}$ and $r_1 = r_2 = 0$. Solid and dashed curves in panels (b) and (c) represent models with ($\bar{g} = 100\,\text{cm}^{-1}$, $\bar{\lambda} = 0$, $\bar{\gamma}_\lambda = 40\,\text{nm}$) and without ($\bar{g} = 0$) gain dispersion.

the field equations 31.1. The solution of the resulting system of ODEs within S_1 can be represented by Equation 31.10, where the transfer matrix M is defined in Equation 31.11. The ratio of the outgoing and incident waves at $z = b_1$ together with the (noninjective) boundary condition (Equation 31.7) at $z = a_1$ define the function $F_l(b_1, \omega)$, which shows the laser response dependence on the optical frequency of the injected field†. In two simple cases of FP and DFB lasers with vanishing facet reflectivity, the response function is given by

$$F_l(b_1, \omega) = \frac{\widehat{E}^+(b_1,\omega)}{\widehat{E}^-(b_1,\omega)} = \begin{cases} -r_1^* e^{-2i\beta|S_1|} e^{-i2\omega n_g |S_1|/c_0}, & \kappa = 0,\; r_1 \neq 0 \;\; \text{(FP laser)} \\ \dfrac{\kappa}{i\eta(\omega)\cot[|S_1|\eta(\omega)] - \mathcal{B}(\omega)}, & \kappa \neq 0,\; r_1 = 0 \;\; \text{(DFB laser)} \end{cases}. \tag{31.13}$$

Figures 31.3b and c show the intensities of these response functions in FP and DFB lasers calculated for different values of carrier densities N. Note also, that the abscissa axis in these figures represents relative wavelengths λ related to the relative frequencies ω by formula $\lambda \approx -\frac{\lambda_0^2}{2\pi c_0}\omega$.

The flat laser response curves in Figure 31.3b indicate an absence of frequency selection mechanisms for FP lasers in our fundamental TW model. Thus, this simple model is not suitable for simulations of FP lasers. In contrast, the wavelength selection in DFB lasers is mainly determined by the Bragg grating, and numerical integration of the TW model can provide reliable information. One should note, however, that the index-coupled DFB laser (characterized by a real coupling factor κ) can emit at one of two resonance wavelengths located at both sides of the stopband, see a solid dark gray curve in Figure 31.3c, and the parameter tuning implied jumping between these two resonances can be expected in simulations. The gain dispersion, in this case, can be exploited for the suppression of one of the resonances [12,21].

Lorentzian Approximation of the Material Gain Function:

There are several methods for introduction of the frequency-selective gain dispersion into the time-domain TW model. Many of these approaches use an additional digital filtering of the numerically calculated optical field time series [30–34]. In some cases, these digital filters are equivalent to the numerical schemes obtained by discretization of some additional integrodifferential operators or differential equations. For the purpose of the analysis of the model equations, it is preferable to introduce the frequency band limiting elements directly into the model equations. For example, the TW model extensions admitting Lorentzian approximation of the material gain dispersion curves can be given by convolution integrals [34] or by an equivalent set of the linear first-order ODEs [21,35]. Another approach to model more sophisticated gain function profiles within the TW modeling frame by including nonlinear polarization equations was used, e.g., in References [22,36,37].

---

† In the same way, one can also define the response function $F_r(a_1, \omega)$ at the left side of the laser.

In this chapter, we follow the strategy proposed in References [12,21]. For this reason, we approximate the gain profile in the frequency domain by a Lorentzian with the amplitude $\bar{g}$, the full width at the half maximum $\bar{\gamma} = \frac{2\pi c_0}{\lambda_0^2}\bar{\gamma}_\lambda$, and the detuning of the peak frequency $\bar{\omega} = -\frac{2\pi c_0}{\lambda_0^2}\bar{\lambda}$. Here, $\bar{\gamma}_\lambda$ and $\bar{\lambda}$ are the wavelength representations of the Lorentzian width and its peak position. In the time domain, this approximation is represented by the additional linear operator $\mathcal{D}$ in the TW field equations, and a pair of linear differential equations for polarization functions $P^{\pm}(z,t)$:

$$\begin{aligned} \frac{n_g}{c_0}\partial_t E^{\pm} &= \mp\partial_z E^{\pm} - i\left(\beta - i\mathcal{D}\right)E^{\pm} - i\kappa E^{\mp} + F_{sp}^{\pm}, \quad z \in S_1, \\ \mathcal{D}E^{\pm} &= \frac{\bar{g}}{2}\left(E^{\pm} - P^{\pm}\right), \quad \partial_t P^{\pm} = \frac{\bar{\gamma}}{2}\left(E^{\pm} - P^{\pm}\right) + i\bar{\omega}P^{\pm}, \quad z \in S_1. \end{aligned} \tag{31.14}$$

The introduction of operator $\mathcal{D}$ also implies the following modification of the stimulated recombination function $\mathcal{S}$ entering the carrier rate equation 31.4:

$$\mathcal{S}(N,E^{\pm}) = \frac{c_0}{n_g}\mathfrak{R}\langle\left(E,[g(N) - 2\mathcal{D}]E\right)\rangle_1. \tag{31.15}$$

To understand the impact of the operator $\mathcal{D}$, we consider the laser response function $F_l(b_1,\omega)$ again according to the modified TW equations 31.14. When repeating the procedure described at the beginning of this section, the factor $\mathcal{B}$ entering Equation 31.11 takes the form

$$\mathcal{B}(\omega) = \beta + \frac{\omega n_g}{c_0} + \chi(\omega), \ \text{ where } \ \chi(\omega) = \frac{\bar{g}}{2}\frac{(\omega-\bar{\omega})}{\bar{\gamma}/2 + i(\omega-\bar{\omega})}, \quad -i\mathcal{D}\widehat{E}(z,\omega) = \chi(\omega)\widehat{E}(z,\omega). \tag{31.16}$$

Thus, an introduction of the linear dispersion operator $\mathcal{D}$ implies modifications of both, gain and refractive index change functions. The total gain (twice the imaginary part of $\beta-(\delta_0 - i\alpha/2)+\chi(\omega)$) and the refractive index change function (real part of the same factor), in this case, are given by the expressions

$$G(N,\omega) = g(N) - \frac{\bar{g}(\omega-\bar{\omega})^2}{(\bar{\gamma}/2)^2 + (\omega-\bar{\omega})^2}, \quad \tilde{N}(N,\omega) = \tilde{n}(N) + \frac{\bar{g}}{4}\frac{\bar{\gamma}(\omega-\bar{\omega})}{(\bar{\gamma}/2)^2 + (\omega-\bar{\omega})^2}. \tag{31.17}$$

The dashed curves in Figures 31.3b and c illustrate the impact of the introduced gain dispersion. Whereas these corrections in the case of DFB lasers (panel [c]) are small, for the FP lasers they provide an efficient wavelength selection mechanism.

It is noteworthy that vanishing factor κ in the field equations 31.2 and 31.14 implies the following simple expression of the monochromatic field *transmission* through the laser section:

$$\widehat{E}^{+}(b_1,\omega) = e^{-i\mathcal{B}(\omega)|S_1|}\widehat{E}^{+}(a_1,\omega), \quad \widehat{E}^{-}(a_1,\omega) = e^{-i\mathcal{B}(\omega)|S_1|}\widehat{E}^{-}(b_1,\omega),$$

where $\mathcal{B}(\omega)$ is defined in Equation 31.16. Thus, the TW equations 31.2 and 31.14 with vanishing functions $g(N)$ and $\tilde{n}(N)$, large Lorentzian amplitude $\bar{g}$, and small Lorentzian width $\bar{\gamma}$ can be effectively used for modeling of the optical filters, i.e., for extracting field frequency components located close to the relative frequency $\bar{\omega}$.

Further Modifications of the Model for Material Gain Dispersion:

The gain peak $g(N)$ and the simple Lorentzian dependence on the optical frequency determined by three fixed parameters $\bar{g}$, $\bar{\gamma}$, and $\bar{\omega}$ define the material gain profile $G(N, \omega)$ in Equation 31.17. To improve fitting of the gain profiles obtained by calculations of microscopic models for various values of N, one can replace these three factors by appropriately selected carrier-dependent functions $\bar{g}(N)$, $\bar{\gamma}(N)$, and $\bar{\omega}(N)$. In the cases, when the gain spectrum has two and more peaks or the asymmetry of the single peak is important, one can also introduce an additional set or several sets of polarization functions $P^{j\pm}(z, t)$. The gain dispersion operator $\mathcal{D}$ and corresponding total gain and refractive index functions, in this case, read as

$$\mathcal{D}^{(s)}E^{\pm} = \sum_{j=1}^{s} \frac{\bar{g}_j}{2}\left(E^{\pm} - P^{j\pm}\right), \qquad \partial_t P^{j\pm} = \frac{\bar{\gamma}_j}{2}\left(E^{\pm} - P^{j\pm}\right) + i\bar{\omega}_j P^{j\pm}, \quad z \in S_1,$$

$$G(N, \omega) = g(N) + 2\Im\chi^{(s)}(\omega), \;\; \tilde{N}(N, \omega) = \tilde{n}(N) + \Re\chi^{(s)}(\omega), \;\; \chi^{(s)}(\omega) = \sum_{j=1}^{s} \frac{\bar{g}_j}{2} \frac{(\omega - \bar{\omega}_j)}{\bar{\gamma}_j/2 + i(\omega - \bar{\omega}_j)},$$

where s is the number of polarization function sets. Since the maximal value of $2\Im\chi(\omega)$ is, in general, smaller than zero, one should also correct the function $g(N)$.

Concluding the discussion of this section, we note that a proper numerical resolution of the gain and refractive index functions (Equation 31.17) for the broad frequency band when simulating the time-domain TW mode requires a careful selection of the numerical algorithm and temporal discretization steps. The size of the frequency band that can be represented by calculated discrete time series is inversely proportional to the time step, whereas the precision of the numerical simulations when approaching borders of this band are rapidly degrading. Thus, a suitable time discretization step should ensure that all important frequency regions (Bragg resonances, surrounding of a gain peak frequency, a frequency of optically injected beams, if present) are within the central part of the allowed frequency band.

31.4 Thermal Detuning

Let us switch now to the consideration of the thermal effects. An increase of the bias current implies changes of the device temperature and, consequently, changes in the refractive index and the lasing wavelength. To model these thermal tuning effects in our device, we supplement the propagation factor β from Equation 31.2 with an additional thermal detuning term $\tilde{n}_T$ [14,38]:

$$\beta = \delta_0 + \tilde{n}(N) + \tilde{n}_T(I) + \frac{i(g(N) - \alpha)}{2}, \qquad \tilde{n}_T = \frac{2\pi n_g}{\lambda_0^2}\nu_1^1 I. \tag{31.18}$$

The linear thermal detuning function $\tilde{n}_T(I)$ determines the impact of the injection current I to the refractive index change. The factor ν_1^1 in solitary lasers determines an approximate red shift of the lasing wavelength due to increased bias current:

$$\nu_1^1 \approx \frac{\Delta_\lambda}{\Delta_I},$$

Here, Δ_I is the bias current tuning interval, whereas Δ_λ is the (continuous) lasing wavelength change during this current tuning.

Figures 31.4a and c show the simulated wavelength change with the increased bias current in the solitary FP and DFB lasers, respectively. Here, besides the dominant optical modes shown in white, one can see other slightly excited optical modes which are (almost) equidistant in the FP case (a) or indicate the DFB laser resonance located on the other side of the stopband. The estimated wavelength shift $\frac{\Delta_\lambda}{\Delta_I} \approx 3.14$ nm/A obtained for the FP laser and 3.09 nm/A for the DFB laser slightly differs from the factor $\nu_1^1 = 3.2$ nm/A

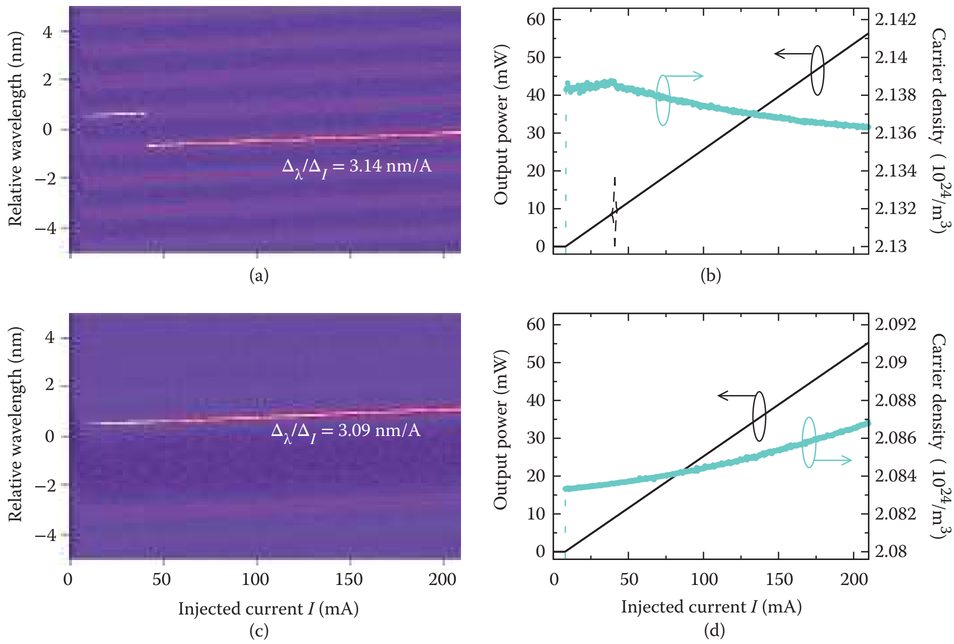


FIGURE 31.4 Mapping of the optical spectra (a), (c), and mean emitted power and carrier density (b), (d) as functions of the increased injected current I in solitary FP (a), (b), and DFB (c), (d) lasers. $\sigma = 2 \cdot 10^{-13}\ \mathrm{m}^2$, $A = 2 \cdot 10^8/\mathrm{s}$, $B = 1 \cdot 10^{-16}\ \mathrm{m}^3/\mathrm{s}$, $C = 1.3 \cdot 10^{-41}\ \mathrm{m}^6/\mathrm{s}$, $\nu_1^1 = 3.2 \cdot 10^{-9}\ \mathrm{m/A}$, whereas other parameters are the same as in Figures 31.3b and c in the case of nonvanishing gain dispersion. White lines and light shading in (a) and (c) represent main and side peaks of the calculated optical spectra. Solid black and gray curves in (b) and (d) show time-averaged emission intensity and carrier density, respectively. Dashed black lines indicate minima and maxima of the emission intensity.

used in our simulations. We attribute this slight discrepancy to the additional contribution of the full refractive index change function $\tilde{N}(N, \omega)$ defined in Equation 31.17. Namely, the dependence of the carrier density N and the relative lasing wavelength λ on the bias current I (see gray curves in Figures 31.4b and d and wavelength shifts in Figures 31.4a and c, respectively) implies nonvanishing changes of the function $\tilde{N}(N, \omega) = \tilde{N}(N, -\lambda c_0/\lambda_0^2)$ that counteracts the thermal detuning term $\tilde{n}_T(I)$ and slightly reduces the redshift of the lasing wavelength.

It is noteworthy that an introduction of the thermal detuning term $\tilde{n}_T$ in our still simple TW model of the solitary laser implies, in general, only a continuous tuning of the lasing frequency. Once achieving threshold, the carrier density changes only slightly (gray curves in Figures 31.4b and d), whereas the emitted field intensity increases linearly without a visible saturation (black curves in the same panels), which is still not taken into account in our model. This linear growth of the lasing wavelength can be correctly understood when analyzing TW field Equation 31.1 with the propagation factor β defined by Equation 31.18 and neglected gain dispersion. Due to the transfer matrix formalism (Equations 31.10 and 31.11) and the expression of $\mathcal{B}$ in Equation 31.11, the extension of β by the nonvanishing real term $\tilde{n}_T$ is equivalent to the change of the relative frequency ω by $-\tilde{n}_T c_0/n_g$, or, alternatively, the change of λ by $\frac{-\lambda_0^2}{2\pi c_0}\frac{-\tilde{n}_T c_0}{n_g} = \nu_1^1 I$.

The unique, more complicated feature in Figure 31.4 is the transition between two states in the FP laser at $I \approx 40\ \mathrm{mA}$, see panels (a) and (b). Figure 31.4a shows that in the vicinity of the transition, these two states are determined by two optical modes belonging to the opposite slopes of the wavelength-dependent gain profile with the peak wavelength at $\bar{\lambda} = 0$. Due to the redshift, all optical modes located on the falling (increasing) slope of this gain profile undergo an increase (decrease) of the detuning from the gain peak wavelength and, consequently, a slight rise (fall) in the mode threshold N; see the gray curves in panel (b) for $I < 40$ mA ($I > 40$ mA). A similar increase of the dominant falling-gain-slope mode threshold can also be seen in Figure 31.4d. At the position of the state transition, the wavelengths of two involved modes are symmetric with respect to the gain peak wavelength and, what is more important, their thresholds become equal. Due to a further tuning of the bias current, the previously suppressed mode at the increasing gain profile slope becomes the minimal threshold mode, is amplified and, finally, turns to be the dominant one. See References [14,15,26] for more details on similar and more complex mode transitions.

Modeling of Cross-Talk Heating Effects in Multisection Devices:

In MSLs devices, one can also use a more advanced model for thermal detuning function $\tilde{n}_T$ which takes into account local and nonlocal cross-talk heating effects [38]:

$$\tilde{n}_T|_{z\in S_k} = \tilde{n}_{T,k} = \tfrac{2\pi n_{g,k}}{\lambda_0^2} \textstyle\sum_{r=1}^{m} \nu_k^r I_r. \tag{31.19}$$

Here, m is a number of sections in the considered MSL. The coefficients ν_k^r of the linear thermal detuning function $\tilde{n}_T(I)$ determine the impact of the injection currents I_r attributed to the sections S_r on the refractive index change within each laser section S_k.

The effect of the thermal detuning in MSLs is much more complicated than that one of the solitary laser. Besides of the red shift of the lasing wavelength, the MSLs can also exhibit periodically or almost periodically reappearing transitions between different states. The change of mean carrier density in various sections during each such period between state changes can be significant and cannot be explained by simple gain saturation or detuning from the gain peak effects. In some cases, a measured variation of the lasing wavelength with an increase or decrease of the injection current in different laser sections, together with the analysis of the field equations provide good estimates of thermal detuning coefficients including cross-talk effects [14,15,38].

Another well-known effect occurring with the heating of the semiconductor laser is the red shift of the gain peak wavelength [39]. If required, these changes can be accounted by the relation [38]

$$\bar{\lambda}|_{z\in S_k} = \bar{\lambda}_k = \bar{\lambda}_k^0 + \textstyle\sum_{r=1}^{m} \bar{\nu}_k^r I_r, \tag{31.20}$$

which is quite similar to the thermal detuning relation (Equation 31.19). Here, $\bar{\lambda}_k^0$ denotes an injection-independent part of the gain peak wavelength in the section S_k, and $\bar{\nu}_k^r$ are linear thermal gain peak detuning coefficients. When applying these expressions, one should be aware that a proper numerical time-domain resolution of a significant (tens or even hundreds of nanometers) gain peak shift requires very small time and, consequently, space discretization steps.

31.5 Spatially Inhomogeneous Carrier Density

Another important extension of the basic TW model takes into account sectionally inhomogeneous distributions of carrier density N. Namely, in this case, the sectionally averaged carrier density function $N(t)$ is replaced by the spatially distributed function $N(z, t)$, $z \in S_1$. This model extension can be especially important in the situations admitting localization of the high-intensity fields within the laser cavity, which takes place, e.g., during propagation of ultrashort optical pulses in mode-locked lasers, or DBR lasers with a high coupling factor κ. Due to stimulated recombination, the high-intensity fields at these localized regions can significantly deplete the carrier distribution causing a spatial hole burning (SHB) of the carriers [12,40].

To achieve a quantitative description of SHB, we replace simple carrier rate Equation 31.4 by the following equation for spatially distributed carrier density:

$$\begin{aligned}\partial_t N(z,t) &= \mathcal{J}(I,N) - \mathcal{R}(N) - \mathcal{S}(N,E^{\pm}), \quad z \in S_1,\\ \mathcal{J}(I,N(z,t)) &= \tfrac{1}{q\sigma|S_1|}\left[I + \tfrac{U_F'}{r_S}\left(\langle N\rangle_1 - N(z,t)\right)\right].\end{aligned} \tag{31.21}$$

Here, $\mathcal{J}$ is the inhomogeneous injection current density [12,41,42], N and $\langle N\rangle_1$ are spatially distributed and sectionally averaged carrier densities, U_F' and r_s denote the derivative of the Fermi level separation with respect to N and the series resistivity, whereas $\mathcal{S}$ is the spatially distributed stimulated recombination function,

$$\mathcal{S}(N,E^{\pm}) = \tfrac{c_0}{n_g}\Re\left(E, [g(N) - 2\mathcal{D}]E\right). \tag{31.22}$$

In the case of the limit $r_s \to 0$, the spatially distributed carrier density, $N(z,t)$, at each position z converges to the sectional average, $N(t) = \langle N\rangle_1$. Since the sectional averaging of the relations 31.21 and 31.22 yields expressions 31.4 and 31.15, the TW models with and without spatial distribution of carriers in this limit case are equivalent.

Figure 31.5 shows some effects occurring due to the SHB of carriers in solitary DFB lasers. The impact of the SHB depends on the injection level. Just above the lasing threshold, the field intensity is small, and the carrier density remains nearly homogeneous, having only a small dip in the center of the laser. With raising injection, this dip increases, but, due to a simultaneous increase of the carrier density at the facets, the mean density remains nearly constant: see only slightly increasing $\langle N\rangle_1$ for $I \leq 90\,\text{mA}$ in panel (b) of the same figure. At these small-to-moderate bias current levels, the carrier density remains symmetric with respect to the laser centrum (dashed curve in panel [d]), and emission at the both facets is the same

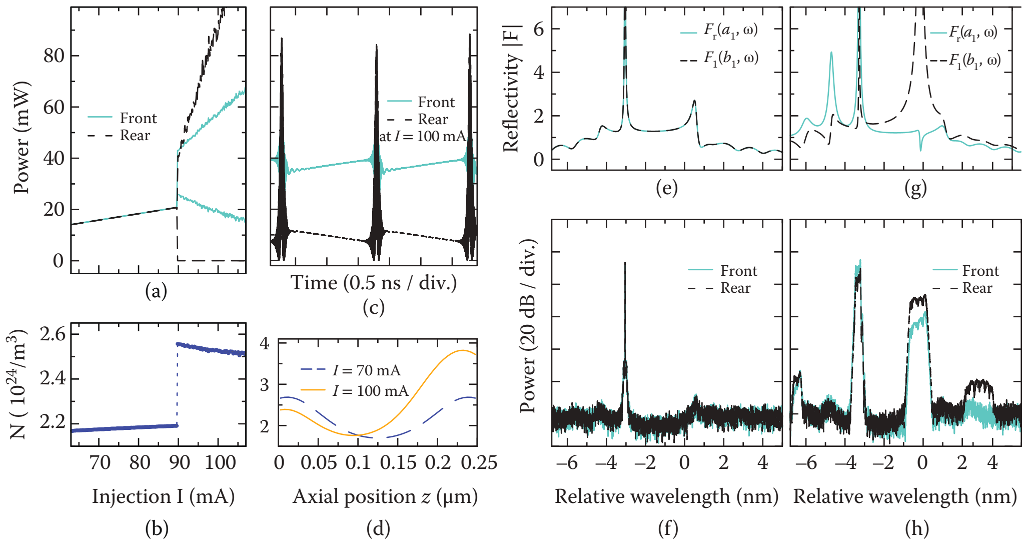

FIGURE 31.5 SHB in solitary DFB laser. (a) Minimal and maximal output power at both facets and (b) sectionally averaged carrier density $\langle N\rangle_1$ as functions of increased bias current. (c) Time trace of the emitted field intensity at both facets for fixed $I = 100\,\text{mA}$. (d) Time-averaged carrier densities for $I = 70\,\text{mA}$ and $I = 100\,\text{mA}$. DFB reflectivity spectra (e), (g), and calculated optical spectra (f), (h) for $I = 70\,\text{mA}$ (e), (f), and $I = 100\,\text{mA}$ (g), (h). Solid gray and black dashed curves in panels (a), (c), (e) through (h) represent optical fields at the front (J_1) and rear (J_2) facets of the laser. $U_F' = 10^{-25}\,\text{Vm}^3$, $r_S = 5\,\Omega$, whereas other parameters are the same as in Figures 31.4c and d except $\nu_1^1 = 0$.

(see coinciding solid gray and black dashed curves in panel (a) for $I \leq 90$ mA and panel (f) at $I = 70$ mA). The inhomogeneous carrier density (dashed curve in Figure 31.5d) causes a corresponding longitudinal variation of the index of refraction. The Bragg resonance of the grating thus has not the identical spectral position along the section but varies over a considerable portion of the stopband [12]. As a consequence, the symmetry of the stopband is lost, and the laser preferably operates on the short wavelength side of its stopband (see Figure 31.5f). The preference of the short-wavelength mode is also shown by the laser response functions $F_l(b_1, \omega)$ and $F_r(a_1, \omega)$ (see Figure 31.5e) calculated for spatially distributed carrier density profile (dashed curve in Figure 31.5d) at $I = 70$ mA according to the formulas 31.10 through 31.12 and the algorithm explained in Section 31.3.

At $I \approx 90$ mA, the symmetric solution loses its stability in symmetry breaking pitchfork bifurcation [43]. According to References [12,43], the supercritical pitchfork bifurcation of the stable symmetric steady state in DFB lasers generates a pair of new stable steady states with asymmetric density profiles (each one the mirror of the other). In our case, the pitchfork bifurcation seems to be of the subcritical type. Instead of finding two asymmetric stable steady states, we immediately jump to the pulsating state with different emission at both laser facets and larger mean carrier density (see panels [a] and (b) for $I > 90$ mA, respectively). The spatial distribution of the carrier density, in this case, is strongly asymmetric, see a solid curve in panel (d). This asymmetry together with noncommuting intermediate transfer matrices M_s from Equation 31.12 implies differences in DFB laser response functions estimated at the front (F_r) and the rear (F_l) sides of the laser, see Figure 31.5g. The optical spectra of the emission at the both sides of the laser (Figure 31.5h) also reveal these differences. Like the response functions of the panel (g), the left (thick gray curves) and the right (thin dashed curves) facet emissions have more pronounced contributions at the shorter and longer wavelength sides of the stopband, respectively.

31.6 Nonlinear Gain Saturation

Until now, our phenomenological models for peak gain and refractive index change (Equation 31.3) were taking into account their dependence on the sectionally averaged or local carrier density N. It is known, however, that the high-intensity optical fields saturate the gain function. To account for such saturation, one can introduce the following modifications of the gain and refractive index functions, which should be used for the definition of the propagation factor β in Equations 31.2 or 31.18 and stimulated recombination function $\mathcal{S}$ in Equations 31.6, 31.15, or 31.22:

$$g(N, E^{\pm}) = g(N)\rho_G(E^{\pm}), \qquad \tilde{n}(N, E^{\pm}) = \tilde{n}(N)\rho_I(E^{\pm}),$$

$$\text{where} \qquad \rho_j = \begin{cases} \left(1 + \varepsilon_j |E|^2\right)^{-1}, & \text{if } N = N(z,t) \\ \left(1 + \varepsilon_j \|E\|^2\right)^{-1}, & \text{if } N = N(t) \end{cases}, \quad j = G, I.$$

Two different parameters, ε_G and ε_I, separately define the nonlinear gain and refractive index dependence on the local or spatially averaged optical field intensity. A typical assumption $\varepsilon_G = \varepsilon_I$ relates the gain and refractive index functions by the linewidth enhancement factor α_H. Another reasonable assumption $\varepsilon_I = 0$, $\varepsilon_G > 0$ [44] used for modeling of high power amplifiers considers the nonlinear compression of the gain function alone.

The importance of the nonlinear gain compression is best visible in high-power lasers and optical amplifiers showing several Watt emission intensity [44]. Some impact of the gain compression in small-to-moderate ($\leq$100 mW) intensity regimes can also be observed when operating in the vicinity of various bifurcations, where a small change of parameters implies qualitative changes of the operating states. We should note, however, that the gain compression, in this case, implies only small shifts of the bifurcation positions, but has no significant impact on the qualitative description of laser dynamics in a large parameter domain. An analysis of simple TW model Equations 31.1 and 31.4 can explain the little influence of the gain compression in these regimes. A nonvanishing gain compression depletes the gain function $g(N)$ what implies a growth of the carrier density needed to reach threshold gain condition g_{th}. In solitary lasers, this growth is given by factor $g_{\text{th}}\varepsilon_G|E|^2/(g'\Gamma)$, which for typical gain compression coefficients and small-to-moderate field intensities is not exceeding a few percents of threshold carrier density. Consequently, a similar (up to a few percent) decay of the emission intensity can be observed.

A somehow different situation occurs in semiconductor ring lasers [19,22,23,45], where a proper introduction of nonlinear gain compression is crucial when deciding the type of operation states. In this case, one should distinguish the gain compression implied by co- and counter- propagating fields:

$$g^{\pm}(N,E^{\pm}) = g(N)\rho_G^{\pm}(E^{\pm}), \qquad \tilde{n}^{\pm}(N,E^{\pm}) = \tilde{n}(N)\rho_I^{\pm}(E^{\pm}),$$
$$\text{where} \quad \rho_j^{\pm} = \begin{cases} \left(1+\varepsilon_{js}|E^{\pm}|^2+\varepsilon_{jc}|E^{\mp}|^2\right)^{-1}, & \text{if } N=N(z,t) \\ \left(1+\varepsilon_{js}\langle|E^{\pm}|^2\rangle+\varepsilon_{jc}\langle|E^{\mp}|^2\rangle\right)^{-1}, & \text{if } N=N(t) \end{cases}, \quad j\in\{G,I\}, \tag{31.23}$$

whereas parameters ε_{js} and ε_{jc}, $j = G, I$, determine self- and cross-saturation of the gain and refractive index functions. In the ring lasers, usually is assumed that $\varepsilon_{Gc} > \varepsilon_{Gs}$, and $\varepsilon_{Ic} > \varepsilon_{Is}$. A detailed analysis based on the Maxwell–Bloch equations showed that the cross-saturation factor for two resonant modes in the ring cavity is twice larger than the self-saturation one [46].

The generalized functions $g^{\pm}$ and $\tilde{n}^{\pm}$ enter the definition of the propagation factor $\beta = \beta^{\pm}$ and the stimulated recombination function $\mathcal{S}$:

$$\beta^{\pm} = \delta_0 + \tilde{n}^{\pm}(N,E^{\pm}) + \tilde{n}_T(I) + \frac{i(g^{\pm}(N,E^{\pm})-\alpha)}{2},$$
$$\mathcal{S}(N,E^{\pm}) = \begin{cases} \frac{c_0}{n_g}\Re\sum_{\nu=\pm} E^{\nu *}[g^{\nu}(N,E^{\pm})-2\mathcal{D}]E^{\nu}, & \text{if } N=N(z,t) \\ \frac{c_0}{n_g}\Re\sum_{\nu=\pm}\langle E^{\nu *}[g^{\nu}(N,E^{\pm})-2\mathcal{D}]E^{\nu}\rangle_1, & \text{if } N=N(t) \end{cases}. \tag{31.24}$$

It is noteworthy that differences in parameters ε_{js} and ε_{jc}, $j = G, I$, imply differences in the propagation factors β^+ and β^- determining the evolution of the fields E^+ and E^-, respectively. These differences are crucial when determining type and stability of operating states in the ring laser, see References [19,23,45] for more details.

To illustrate how an asymmetry of the self- and cross-gain saturation implies different operation states in the ring laser (see Figure 31.2b), we have simulated the TW model equations 31.14, 31.21, 31.8, 31.5, 31.23, 31.24, 31.3 for vanishing ε_{Is} and ε_{Ic}, fixed nonvanishing sum $\varepsilon_{Gc} + \varepsilon_{Gs} = C > 0$ and tuned difference $\varepsilon_{Gc} - \varepsilon_{Gs}$. Figure 31.6 shows the results of these simulations. Solid gray and dashed black curves in all panels of this figure represent clockwise (CW) and counter-clockwise (CCW) propagating field functions $E^-(b_1, t)$ and $E^+(a_1, t)$ at the point scattering source J_1, respectively (see Figure 31.2b). Panel (a) of this figure gives an overview of all obtained states when tuning $\varepsilon_{Gc} - \varepsilon_{Gs}$ from $-C$ (full self-saturation with vanishing ε_{Gc}) up to $+C$ (full cross-saturation with vanishing ε_{Gs}). Panels (b)–(e) of the same figure represent four different observed dynamic regimes. The first three regimes occurring with a consequent increase of the cross-gain saturation are the bidirectional stable stationary state (b), the alternate oscillations (c), and the unidirectional bistable state (d). These three regimes can be observed experimentally and recovered theoretically using a simple two-mode ODE model [19]. An analysis of the TW model performed in Reference [23] has explained the relation between the asymmetry of the gain compression factors, ε_{Gc} and ε_{Gs}, and stability of the bidirectional steady state (regime b) or unidirectional bistable states (regime d). It was also shown, how the difference $\beta^+ - \beta^-$ and localized backscattering r_1 determine the frequency of alternating oscillations (regime c).

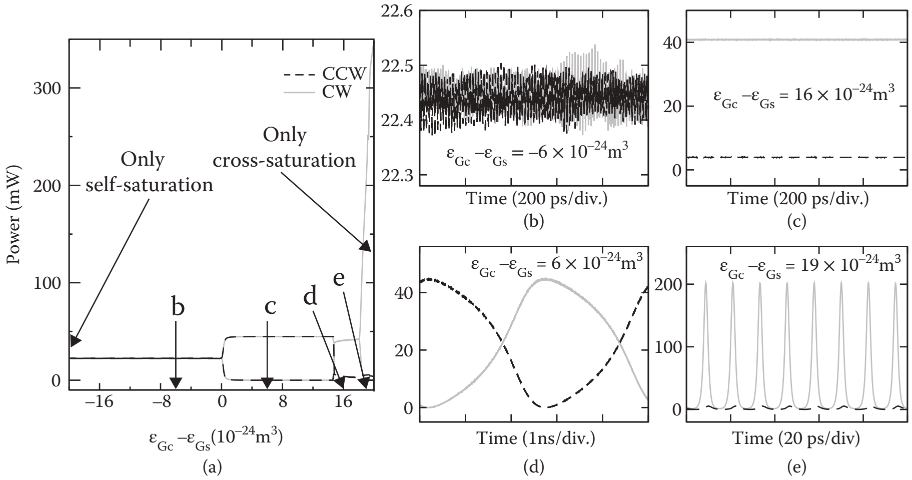

FIGURE 31.6 Dynamic regimes for different contributions of the cross- and self-gain saturations. (a) Maximal and minimal intensities of the optical fields at J_1 for changing values of $\varepsilon_{Gc} - \varepsilon_{Gs}$ but fixed $\varepsilon_{Gs} + \varepsilon_{Gc} = 20 \cdot 10^{-24}$ m^3. (b)–(e) Typical representatives of the observed regimes. Thick gray and dashed black curves indicate clockwise (CW) and counter-clockwise (CCW) propagating fields. Parameters are similar to those of Figures 31.4a and b, only $|S_1| = 1000\,\mu$m, $\alpha_H = -2$, $\alpha = 2\,\text{cm}^{-1}$, $\nu_1^1 = \varepsilon_{Is} = \varepsilon_{Ic} = 0$, $I = 100$ mA. U_F' and r_S are the same as in Figure 31.5, whereas the field transmission and localized backscattering parameters at J_1 are $t_1 = \sqrt{0.7}$ and $r_1 = 0.007$, respectively.

The last simulated regime (e) was observed for the dominant cross-gain saturation. Like usual mode-locking pulsations, this regime is characterized by large short pulses occurring with the round-trip period. However, in contrast to the mode-locking observed in multisection ring lasers [47], this state is unidirectional and does not require any fast saturable absorption. Similar mode-locked pulsations in a single-section ring laser were found and discussed theoretically in Reference [45].

31.7 Further Modifications of the TW Model

There exist a vast number of further possible modifications of the TW model for MSLs. Each of these modifications, however, requires a few new not very well-known parameters and, therefore, should be used with the great care. On the other hand, some of these modifications being crucial when analyzing a particular group of MSLs can be irrelevant for simulations and analysis of different type MSLs. Later we present several modifications of the TW model used for investigation of specific types of MSLs.

Multiple Carrier Rate Equations in QD Lasers:

When modeling QD lasers, one should take into account carrier exchange processes between a carrier reservoir (CR) and discrete levels in QDs.

One of the simplest ways to account for all these transitions within the TW modeling frame is provided by the rate equations for the normalized carrier density $N^{cr}(z, t)$ (scaled by the factor Θ_N) within the CR, and occupation probabilities $N^{gs}(z, t)$, $N^{es}(z, t)$ of the ground state (GS) and the first excited state (ES) of QDs, respectively [10,48,49].

To keep the structure of the TW field equations 31.14 unchanged, we neglect the inhomogeneous spectral broadening effect due to QD nonuniformity and consider a simple single-Lorentzian gain spectrum profile, which limits the material gain bandwidth. Besides, we assume that the laser operates at the GS transition only. In this case, the propagation factor β depends on the ground state occupation probability

$N^{gs}(z,t)$ only. The expression of $\beta(N^{gs})$ is equivalent to that one given by Equations 31.2 and 31.3 with spatially distributed occupation probability $N^{gs}(z) \in [0,1]$ and factor 1/2 instead of the carrier density $N(z,t)$ and transparency carrier density N_{tr}, respectively.

To describe carrier exchange processes between the CR, GS, and ES of the QDs in the active section (see Figure 31.7a), we use the following set of rate equations:

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t}N^{gs}(z,t) &= -\frac{N^{gs}}{\tau_{gs}} + 2\left(\frac{N^{es}(1-N^{gs})}{\tau_{es\to gs}} - \frac{N^{gs}(1-N^{es})}{2\tau_{gs\to es}}\right) - \frac{1}{\theta_E}\mathcal{S}(N^{gs},E^{\pm}),\\
\frac{\mathrm{d}}{dt}N^{es}(z,t) &= -\frac{N^{es}}{\tau_{es}} - \left(\frac{N^{es}(1-N^{gs})}{\tau_{es\to gs}} - \frac{N^{gs}(1-N^{es})}{2\tau_{gs\to es}}\right) + \left(\frac{N^{cr}(1-N^{es})}{4\tau_{cr\to es}} - \frac{N^{es}}{\tau_{es\to cr}}\right),\\
\frac{\mathrm{d}}{\mathrm{d}t}N^{cr}(z,t) &= \frac{I}{q|S_1|\theta_I} - \frac{N^{cr}}{\tau_{cr}} - 4\left(\frac{N^{cr}(1-N^{es})}{4\tau_{cr\to es}} - \frac{N^{es}}{\tau_{es\to cr}}\right).
\end{aligned} \tag{31.25}$$

Here, $\mathcal{S}(N^{gs},E^{\pm})$ is defined by Equation 31.22, whereas τ_a^{-1} and $\tau_{a\to b}^{-1}$, $a,b \in \{gs,es,cr\}$, denote spontaneous relaxation and transition rates between GS, ES, and CR, respectively. Factors $(1-N^{gs})$ and $(1-N^{es})$ represent the Pauli blocking, factors 2 and 4 account for the spin degeneracy in the QD energy levels. Note that here we neglect direct transitions between CR and GS. θ_I and $\theta_E = \frac{2hc_0\theta_I}{\lambda_0}$ are scaling factors relating the injection current I, the field intensity $|E|^2$, the CR scaling factor θ_N, the differential gain g', and the QD density in the active zone.

In the saturable absorption sections (see Figure 31.7b), there is no pumping, $I = 0$, so that the transitions from CR to ES can be neglected, $\tau_{cr\to es} \to \infty$, and the last of the equations 31.25 can be ignored. The carrier transition from ES to CR can be added to similar spontaneous recombination term: $\bar{\tau}_{es}^{-1} = \tau_{es}^{-1} + \tau_{es\to cr}^{-1}$. Following Reference [48], one can model the carrier transitions in the negatively driven saturable absorber

FIGURE 31.7 Schematic representation of carrier transitions in (a) the gain section and (b) the saturable absorption section of the QD MSL. Crossed arrows in panel (b) indicate the transitions which are neglected in the model equations. A sequence of (c) the emitted mode-locking pulses with an enhanced trailing edge plateaux at both sides of the laser and (d) the sectionally averaged carrier functions $N^{gs,es,cr}$ in both laser sections. All parameters and a detail description of the MSL device can be found in References [10,49].

by assuming an exponential decay of $\bar{\tau}_{es}$ with growing negative voltage U, whereas all other relaxation rates remain unchanged.

Figures 31.7c and d presents an example of simulated mode-locked QD laser containing an amplifying and a saturable absorber sections S_1 and S_2. Panel (c) of this figure gives an evidence of strongly asymmetric pulses with a broad trailing edge plateau. Our theoretical analysis has shown that such pulses arise mainly due to noninstant carrier transitions between the CR, ES, and GS of the QD laser shown in panel (d) of the same figure. The presence of these transitions exert a smoothening effect on all spatial/temporal carrier and field intensity distributions and, in turn, imply a broadening of the trailing edge of the pulse. We have also found that an increase of the intradot transition rates leads to a reduction of the filtering effect and, hence, to a growth of the pulse peak intensity and narrowing of the pulse and its trailing edge. More details on our analysis as well as experimental demonstration of such asymmetric pulses can be found in Reference [10,49].

Further modifications of the TW model can be used for more precise simulations of QD lasers. For example, one can improve the model of carrier transitions (Equation 31.25) by separate consideration of electrons and hole densities [50]. To allow a simultaneous radiation on the spectrally well-separated ground and ES, one can introduce another pair of TW equations for optical fields [51]. An inhomogeneous spectral broadening and an accompanying description of the radiation at GS and ES can also be modeled by an introduction of multiple sets of carrier rate and polarization equations representing carrier transitions within the QDs of different size and their impact on the laser emission at different wavelengths [52].

Nonlinear Gain and Refractive Index Functions:

In the earlier discussion, the gain and the refractive index dependence on the carrier density N was modeled by linear functions related to each other by the linewidth enhancement factor α_H. This modeling approach is reasonable for small and slow variation of carrier density N, but can fail once N exhibits some significant changes, see, e.g., Figure 31.5d, where a variation of the spatially distributed $N(z,t)$ was of the order of the mean value of the carrier density. In such situations, one should better use nonlinear peak gain functions, $g(N)$, which can better represent measured or precalculated gain spectra profiles. For this reason, the following logarithmic gain peak function dependence on the carrier density is frequently used:

$$g(N) = \Gamma g' N_{\mathrm{tr}} \ln\left(\frac{\max\{N, N^*\}}{N_{\mathrm{tr}}}\right), \qquad \tilde{n}(N) = \frac{\alpha_H g(N)}{2}. \tag{31.26}$$

Here, N^* indicates a cutoff carrier density value, which prevents the convergence $g(N) \to -\infty$ with carriers $N \to 0$. These expressions for the gain and index change functions replace the relations 31.3 used in the TW models discussed earlier.

Another issue is related to the linewidth enhancement factor α_H. Initially, this factor was used to relate gain and refractive index functions at a fixed value of N. Such approach implies a rather simple model for propagation factor, β, and can be quite useful when performing an advanced analysis of model equations. In reality, however, the ratio between the gain and refractive index is not a constant, but a function depending on carrier density, temperature, and several other factors not discussed in this chapter. Thus, an experimental estimation of this factor in the semiconductor laser operating at different conditions or using different methods can lead to rather different values of α_H. For this reason, it can be preferable to use separately defined nonlinear peak gain and index change functions $g(N)$ and $\tilde{n}(N)$. These functions depend on the properties of the semiconductor material and the design of the device, and, therefore, should be adjusted individually for each considered laser.

A satisfactory description of these functions for a broad class of semiconductor lasers is given by the logarithmic, and the square-root-like expressions [38]

$$g(N) = \Gamma g' N_{\mathrm{tr}} \ln\left(\frac{\max\{N, N^*\}}{N_{\mathrm{tr}}}\right), \qquad \tilde{n}(N) = \tilde{n} + \alpha_H \Gamma g' \sqrt{N \cdot N_{\mathrm{tr}}}. \tag{31.27}$$

Here, $\tilde{n}$ represents the offset of the refractive index change function, $\Gamma g' = \partial_N g(N_{\text{tr}})$, and $\alpha_H = 2\partial_N \tilde{n}(N_{\text{tr}})/\partial_N g(N_{\text{tr}})$ is the linewidth enhancement factor evaluated at the transparency carrier density N_{tr}.

We should admit, however, that linear formulas 31.3 with slightly corrected factors g', α_{H}, N_{tr}, and a proper selection of δ_0 can be used for approximation of nonlinear functions 31.27 not only in the vicinity of N_{tr} but also over a larger range of densities N including the threshold density N_{th}. In many cases, the simplifications of the gain and refractive index functions still imply qualitatively the same results when performing simulations of MSLs with varying parameters [53].

31.8 Multisection Lasers and Coupled Laser Systems

A vast variety of MSLs and coupled laser systems can be represented as a set of differently interconnected laser sections, each characterized by its material and geometry parameters. To distinguish these parameters or functions attributed to different laser sections, we shall use the lower indices. For example, α_k, $g_k(N)$, and a_k denote the field losses, the gain function and the left-edge coordinate of the section S_k. Note also that for unique identification of longitudinal coordinate z within all laser sections, different sections of our device are represented by nonoverlapping intervals (a_k, b_k).

According to our laser device construction, for any edge of all sections S_k, we can attribute a unique junction J_l. On the other hand, each junction has, at least, one section joining it from one or another side, see, e.g., Figure 31.1, where MSLs are represented as sets of laser *sections* mutually interconnected through different *junctions*. To explain the relations between section edges, corresponding junctions, and applied optical injections, we use the following notations in the sequel of this chapter. By l we denote the index of the junction J_l, as well as optical fields and the section edges attributed to this junction. l' (l'') is the vector of length $|l'|$ $(|l''|)$ containing indices of the sections connected to J_l by their left (right) edge $a_{l'_j}$ $(b_{l''_j})$; see Figure 31.8a. $l^e = |l'| + |l''| \geq 1$ is a total number of such section edges connected to J_l. By $o_l(t)$ and $E_l^{\text{out}}(t)$ we denote the applied optical injection and the recorded emission at the same junction, see solid and dashed thick light gray arrows in Figure 31.8a. When the injection or emission at J_l is absent, the corresponding function is simply set to zero.

General field scattering conditions at the arbitrary junction J_l are defined by the $l^e \times l^e$ dimensional complex field scattering matrix $\mathcal{T}_l$, $l^e \times 1$ dimensional injection distribution matrix $\mathcal{T}_l^i$, and $1 \times (l^e + 1)$

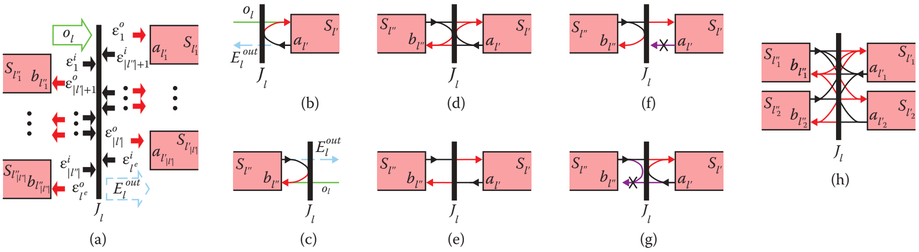

FIGURE 31.8 Schematic representation of different interfaces between the sections at the junction J_l. (a) general configuration, (b) and (c) field reflection and optical injection at laser facets, (d) and (e) reflecting (transmission and reflection) and trivial (transmission only) interface of two section edges, (f) and (g) directionally absorbing interfaces of two section edges for modeling of a master–slave laser system, and (h) transmitting/reflecting interface of four section edges for modeling ring lasers with an outcoupling waveguide. Black segments and gray frames represent junction J_l and all section edges connected to this junction, respectively. Black and dark gray arrows in all diagrams represent all components of the vector fields $\mathcal{E}_l^i$ and $\mathcal{E}_l^o$, respectively. Optical injections o_l and emitted fields E_l^{out} are shown by solid and dashed light gray arrows. Crossed arrows in panels (f) and (g) represent a full absorption of the corresponding fields.

dimensional outcoupling matrix $\mathcal{T}_l^o$:

$$\begin{aligned}
&\mathcal{E}_l^o = \mathcal{T}_l\mathcal{E}_l^i + \mathcal{T}_l^i o_l, \quad E_l^{\text{out}} = \mathcal{T}_l^o \begin{pmatrix} \mathcal{E}_l^i \\ o_l \end{pmatrix}, \qquad \text{where} \\
&\mathcal{E}_l^o = \left(E^+_{l'_1}(a_{l'_1},t), \dots, E^+_{l'_{|l'|}}(a_{l'_{|l'|}},t), E^-_{l''_1}(b_{l''_1},t), \dots, E^-_{l''_{|l''|}}(b_{l''_{|l''|}},t)\right)^T, \\
&\mathcal{E}_l^i = \left(E^+_{l''_1}(b_{l''_1},t), \dots, E^+_{l''_{|l''|}}(b_{l''_{|l''|}},t), E^-_{l'_1}(a_{l'_1},t), \dots, E^-_{l'_{|l'|}}(a_{l'_{|l'|}},t)\right)^T.
\end{aligned} \tag{31.28}$$

The vector functions $\mathcal{E}^i$ and $\mathcal{E}^o$ (see black and dark gray arrows in Figure 31.8a) denote the internal optical fields, which are incident into the junction from all adjacent sections and are scattered from the junction back into these sections, respectively.

In most cases, the interfaces between the sections are much simpler. For example, the scattering matrices at the facets of the solitary laser (Figures 31.8b and c as well as junctions J_1 and J_2 in Figure 31.2a) are determined by the boundary conditions (Equation 31.7), i.e.,

$$\begin{cases} \mathcal{T}_l = -r_l^*, \ \mathcal{T}_l^i = 1, \ \mathcal{T}_l^o = (t_l, 0), & \text{single "left" edge } a_{l'}, \ |l'| = 1, \ |l''| = 0 \\ \mathcal{T}_l = r_l, \ \mathcal{T}_l^i = 1, \ \mathcal{T}_l^o = (t_l, 0), & \text{single "right" edge } b_{l''}, \ |l''| = 1, \ |l'| = 0 \end{cases}, \tag{31.29}$$

where r_l and t_l are field reflection and transmission coefficients,

$$|r_l| \le 1, \qquad t_l \le \sqrt{1 - |r_l|^2}. \tag{31.30}$$

Another frequently used case in MSLs is the interface of two adjacent sections (Figures 31.8d through g). At such interfaces, we have no optical injections and field emission, so that we can set $\mathcal{T}_l^i = (0,0)^T$ and $\mathcal{T}_l^o = (0,0,0)$. The scattering of the field at J_l, in this case, is entirely defined by the 2×2 dimensional matrix

$$\mathcal{T}_l = \begin{pmatrix} t_l & -r_l^* \\ r_l & t_l \end{pmatrix}, \tag{31.31}$$

where t_l and r_l satisfy the conditions 31.30 (see Figure 31.8d and, e.g, J_3 in Figure 31.1a). Here, the nonvanishing reflections r_l can appear, e.g., due to different heterostructure of the adjacent sections. In the simplest case of $r_l = 0$ and $t_l = 1$, $\mathcal{T}_l$ is an identity matrix, and the interface admits a full transmission of the optical fields (see Figure 31.8e and J_2 in Figure 31.1a).

When modeling the master–slave laser system (S_1 and S_2 in Figure 31.1d), only one-directional field propagation should be allowed in the air gap between two lasers (section S_3 in the same figure). This effect can be achieved by modification of otherwise standard scattering matrices $\mathcal{T}_l$ (Equation 31.31) at one of the gap section edges. One can model a full absorption of the backward incident beam at the interface of the master laser and the gap section (see Figure 31.8f and J_2 of Figure 31.1d), or prohibit the field backscattering into the air gap at the interface of the slave laser and the gap section (Figure 31.8g and J_3 of Figure 31.1d). Formally, both these situations can be defined by the scattering matrices

$$\mathcal{T}_j = \begin{pmatrix} t_j & 0 \\ r_j & 0 \end{pmatrix} \ \text{(master-gap interface)}, \qquad \mathcal{T}_j = \begin{pmatrix} t_j & -r_j^* \\ 0 & 0 \end{pmatrix} \ \text{(gap-slave interface)}.$$

More complicated situations occur at the junctions connecting more than two section edges of the MSL. For example, Figure 31.8h and J_1 of Figure 31.1e represent an interface connecting two "left" and two "right" section edges. This situation is used for modeling of a localized coupling of the ring laser (section S_1 in Figure 31.1e) and the outcoupling waveguide (S_2 and S_3 in the same figure).

Similarly to the previously discussed case, the optical injection- and field emission-relevant matrices can be defined by $\mathcal{T}_l^i = (0,0,0,0)^T$ and $\mathcal{T}_l^o = (0,0,0,0,0)$. By assuming a nonvanishing field reflection r_l at the ring laser part of this junction (section edges $b_{l_1''}$, $a_{l_1'}$ in Figure 31.8h or b_1, a_1 in Figure 31.1e), we model a *localized* linear backscattering of the fields [23,37]. The 4×4 dimensional scattering matrix $\mathcal{T}_l$, in this case, can be defined as

$$\mathcal{T}_l = \begin{pmatrix} t_l & i\tilde{t}_l & -r_l^* & 0 \\ i\tilde{t}_l & t_l & 0 & 0 \\ r_l & 0 & t_l & i\tilde{t}_l \\ 0 & 0 & i\tilde{t}_l & t_l \end{pmatrix}, \qquad t_l^2 + \tilde{t}_l^2 + |r_l|^2 \le 1. \tag{31.32}$$

Here, t_l is a real field amplitude transmission factor within the same (ring or outcoupling) waveguide and $i\tilde{t}_l$ is an imaginary coefficient representing part of the field amplitude, which is outcoupled from the ring or transmitted into the ring from the external waveguide. It is noteworthy that a proper estimation of the transmission–reflection–outcoupling matrix $\mathcal{T}_l$ in the ring laser case requires some appropriate measurements or an advanced modeling. Such modeling should take into account the curvature of the ring cavity, the length of the coupling regions, the field diffraction, and the overlapping of the lateral modes in the coupling region [54]. Moreover, the coefficients of the scattering matrix are, in general, frequency dependent. In our TW modeling approach, we use constant coefficients describing field scattering at the central reference frequency.

31.9 Simulations of Nontrivial MSL Device

The concept of differently interconnected *sections* and *junctions* allows modeling rather complicated MSLs. One of such nontrivial configurations is a semiconductor ring laser with four separate branches of the filtered optical feedback, see Figure 31.9a. The multichannel feedback scheme of this laser admits a fast switching between steady states determined by the resonances of the ring laser and the wavelengths of the activated filtering channels [55].

The gray-shaded frames in Figure 31.9a represent device sections of different types. Namely, we distinguish here the amplifying sections $S_{A\cdot}$, where the field and carrier dynamics is governed by the full TW model (Equations 31.5, 31.14, 31.21, 31.23, 31.24, 31.26), and two kinds of passive sections, $S_{P\cdot}$ and $S_{F\cdot}$, where gain and refractive index functions are set to zero, allowing to ignore the carrier rate equations at all. The notations of all sections in the section indexes are made according to the cardinal directions "n," "e," "s," and "w".

Almost all parameters of the TW model in all sections of our MSL are the same as in Figure 31.6. A few exceptions are parameters $\alpha_H = -4$ and $\bar{\gamma}_\lambda = 100\,\text{nm}$. In the passive waveguiding sections, $S_{P\cdot}$ (medium gray), we assume $|S_{Pe}| = |S_{Pw}| = 330\,\mu\text{m}$, $|S_{Pne}| = |S_{Pnw}| = 50\,\mu\text{m}$, $|S_{Pse}| = |S_{Psw}| = 2500\,\mu\text{m}$, and neglect the gain dispersion, $\bar{g} = 0$. In the passive filtering sections, $S_{F\cdot}$ (light gray), we assume $|S_{F\cdot}| = 530\,\mu\text{m}$ and significantly modify the profile of Lorentzian gain dispersion by setting $\bar{g} = 5 \cdot 10^4\,\text{m}^{-1}$ and $\bar{\gamma}_\lambda = 4\,\text{nm}$. The relative peak wavelengths of four filtering branches (sections S_{Fwj} and S_{Fej}, $j = 1, \ldots, 4$) are $\bar{\lambda} = -2, -0.67, 0.67$, and $2\,\text{nm}$, respectively. Finally, in the amplifying sections (dark gray) within the primary ring laser, S_{Ajk}, $j = n, s$ and $k = e, w$, we use $|S_{A\cdot}| = 380\,\mu\text{m}$, $\varepsilon_{Gs} = 6 \cdot 10^{-24}\,\text{m}^3$, $\varepsilon_{Gc} = 2\varepsilon_{Gs}$, and the bias currents $I = 26\,\text{mA}$, which is 1.5 times higher than the lasing threshold in the laser without feedback. In the amplifying sections belonging to the four filtering branches, S_{Asj}, $j = 1, \ldots, 4$, we assume $|S_{A\cdot}| = 190\,\mu\text{m}$ and $\varepsilon_{Gc} = \varepsilon_{Gs} = 9 \cdot 10^{-24}\,\text{m}^3$. Once the bias current in these sections is zero, $I = 0\,\text{mA}$,

FIGURE 31.9 (a) Scheme of the semiconductor ring laser with four branches of filtered and amplified unidirectional optical feedback. Black segments and gray-shaded frames indicate junctions and different sections of the MSL. Solid light-gray and dashed black arrows show propagation directions and the emission of the fields E^+ and E^-, respectively. (b) Transmission spectra of four filtering branches. Maximal transmission at $I_{Asj} = 10\,\text{mA}, j = 1, \ldots, 4$ is approximately 1.6. (c) Stabilization of the multimode behavior of the ring laser (black) by the single-branch filtered feedback (gray). (d) Dependence of the lasing wavelength on the feedback phase once the second filtering branch is activated.

the feedback branches are efficiently absorbing the optical fields. To activate one of the feedback branches, we set the corresponding injection $I = 10\,\text{mA}$.

The field transmission and reflection conditions at J_n and J_s are given by the conditions 31.32 with $r = 0$, $t = \sqrt{0.8}$, and $\tilde{t} = \sqrt{0.2}$. At J_{se} and J_{sw}, we neglect all possible reflectivity, admit full-field transmission from filtering branches to the passive waveguide sections S_{Psw} or S_{Pse}, equally distribute the intensity of the optical field E^+ propagating from S_{Pse} to the filtering branches, and fully absorb E^- at J_{sw}:

$$E^-(b_{Pse}, t) = \textstyle\sum_{j=1}^{4} E^-(a_{Fej}, t), \qquad E^+(a_{Fej}, t) = \sqrt{\tfrac{1}{4}}\, E^+(b_{Pse}, t), \quad j = 1, \ldots, 4;$$

$$E^+(a_{Psw}, t) = \textstyle\sum_{j=1}^{4} E^+(b_{Fwj}, t), \qquad E^-(b_{Fwj}, t) = 0, \quad j = 1, \ldots, 4.$$

At J_w and J_e, the fields E^+ and E^- are emitted from our MSL. Here, the field reflection–transmission conditions are given by (Equation 31.29) with the reflectivity factors $r_w = r_e = 0.1$. All other junctions of this MSL are trivial, i.e., the optical fields cross the interfaces according to the relations 31.31 with $r_l = 0$ and $t_l = 1$.

A series of simulations represented in the remaining panels of Figure 31.9 are in good agreement with the experimental results reported in Reference [55]. First of all, panel (b) shows the transmission spectra (modulus of the wavelength-dependent complex transmission function) of the optical fields E^+ propagating through each of four optical feedback branches activated by the injected current into the corresponding amplifying section. For 10 mA injections used in these simulations, the peak amplitude transmission is around 1.6.

Panels (c) and (d) of Figure 31.9 show simulated optical spectra of the emitted field at the “west” facet J_w of the MSL for different operation conditions. An upper black curve in panel (c) represents the optical spectrum in the case of deactivated feedback branches. Multiple significant spectral peaks with the mode separation corresponding to the field round-trip time in the ring laser indicate a multimode lasing of the laser. An optical field E^+ propagating along the filtering branches, however, is not entirely absorbed. For higher ring laser injections, we observed the steady states determined by a single ring resonance mode. In these cases, the amplifier within corresponding filtering branch was optically pumped, and the related peak amplitude transmission was around 0.2. The competition between nominally equivalent unpumped filtering branches, however, does not allow predicting the lasing wavelength of such a steady state.

The four lower spectra in Figure 31.9c represent switching between different optical modes by activation of the corresponding filter and deactivation of the remaining ones. A close inspection of these spectra shows, that whereas the first and the fourth filters select the resonance modes which are closest to the filter peak position, the third, and, especially, the second filter prefers modes admitting smaller optical feedback. We have found, that this mode selection is related to the phase of the optical field within the filtering branch. Figure 31.9d demonstrates, how tuning of the feedback phase within the second filtering branch (realized by variation of the detuning factor $\delta_{0,Fw2}$) implies changes between the resonant modes located within the filtering band.

In conclusion, we have simulated the MSL consisting of 22 sections interconnected at 18 junctions. Our theoretical findings were in a good qualitative agreement with experimental observations of similar ring laser device reported in Reference [55].

31.10 Beyond Numerical Simulations of the TW Model

In the previous sections, we have introduced different modifications of 1+1 dimensional TW model suited for simulations of various MSL devices and coupled laser systems. In the remaining part of this chapter, we introduce the concept of instantaneous optical modes and present several applications of these modes for an advanced analysis of MSLs. In all these cases, we consider MSLs without optical injection and neglect a contribution of Langevin noise term $F_{sp}^{\pm}$, which is of minor importance in the lasers operating well above threshold.

Instantaneous Optical Modes:

The concept of optical modes plays a significant role in understanding laser dynamics in general. They represent the natural oscillations of the electromagnetic field and determine the optical frequency and the lifetime of the photons contained in the given laser cavity. The *instantaneous* optical modes correspond to a fixed *instant* distribution of the propagation factor β [26].

In general, compared to a variation of the optical fields, the changes of the carrier density N are slow. The change of N is mainly determined by the carrier relaxation time which, typically, is measured in nanoseconds (or tens of picoseconds when considering saturable absorbers). On the other hand, picosecond or sub-picosecond time windows are sufficient for significant changes of the photon densities. Since the gain compression for small and moderate field intensities is also small, the propagation factor β experiences only minor modifications in the picosecond range. For this reason, in the remaining part of this chapter we analyze the field equations for the frozen distribution of the propagation factor $\beta(z, t_0)$ at the time instant t_0.

The instantaneous optical modes of MSLs are pairs $(\Omega(\beta), \Theta(\beta, z))$ of complex frequencies Ω and vector-functions $\Theta = (\Theta_E^+, \Theta_E^-, \Theta_P^+, \Theta_P^-)^T$, where imaginary and real parts of $\Omega(\beta)$ are mainly defining the angular frequency and the damping of the mode, whereas $\Theta(\beta, z)$ determines the spatial distribution of the mode.

Complex frequencies Ω and vector-functions $\Theta(\beta, z)$ solve the linear system of algebro-differential equations

$$\begin{cases} \frac{\mathrm{d}}{\mathrm{d}z}\Theta_E^+ = -i\mathcal{B}(\Omega)\Theta_E^+ - i\kappa\Theta_E^- \\ \frac{\mathrm{d}}{\mathrm{d}z}\Theta_E^- = i\mathcal{B}(\Omega)\Theta_E^- + i\kappa\Theta_E^+ \\ \Theta_P^\pm(\beta, z) = \frac{\bar{\gamma}/2}{\bar{\gamma}/2 + i(\Omega - \bar{\omega})}\Theta_E^\pm(\beta, z) \end{cases}, \quad z \in S_k\Big|_{k=1}^{n}, \qquad \theta_l^o(\beta) = \mathcal{T}_l\theta_l^i(\beta)\Big|_{l=1}^{m}, \tag{31.33}$$

obtained by assuming a nonvarying in time propagation factor, $\partial_t\beta = 0$, and substituting the expressions

$$E^\pm(z, t) = \Theta_E^\pm(\beta; z)e^{i\Omega(\beta)}, \qquad P^\pm(z, t) = \Theta_P^\pm(\beta; z)e^{i\Omega(\beta)}$$

into the field equations 31.14 within each of n sections S_k, and boundary conditions 31.28 at each of m junctions J_l. Similarly to the vector functions $\mathcal{E}_l^o$ and $\mathcal{E}_l^i$ in Equation 31.28, complex vectors $\theta_l^i(\beta)$ and $\theta_l^o(\beta)$ in Equation 31.33 represent functions $\Theta_E^\pm(\beta, z)$ at the section edges $z = a_{l'_j}$ or $z = b_{l''_j}$ connected by the junction J_l. The function $\mathcal{B}(\Omega)$ entering Equations 31.33 is defined in 31.16.

Each pair of linear ODEs in Equation 31.33 can be solved by the transfer matrix† 31.11 with the coefficients nonlinearly depending on still unknown complex frequency Ω. These matrices define $2n$ homogeneous linear equations relating $4n$ components of the complex vector $\mathcal{S} = (s_1, \ldots, s_{4n})^T$ representing field functions $\Theta_E^\pm(\beta, z)$ at both edges of all sections S_k. Another $2n$ homogeneous linear equations relating the same complex numbers are given by the field scattering matrices $\mathcal{T}_l$ at all junctions J_l. In such a manner, we build a linear $4n$ dimensional algebraic system

$$\mathcal{M}(\beta, \kappa; \Omega)\mathcal{S} = 0,$$

determined by a sparse $4n \times 4n$ dimensional matrix $\mathcal{M}$. Nontrivial solutions $\mathcal{S}$ (i.e., nontrivial functions Θ of the problem 31.33) are available only for those Ω which are the complex roots of the complex characteristic equation

$$\det \mathcal{M}(\beta, \kappa; \Omega) = 0. \tag{31.34}$$

The finite number of these roots can be found using Newton iterations and the homotopy method; see Reference [26] for more details.

It is noteworthy that linear configurations of MSLs admit rather simple expressions of the characteristic equations 31.34 involving the response functions $F_l(z, \Omega)$ and $F_r(z, \Omega)$ defined at some longitudinal position z of the MSL:

$$\det \mathcal{M}(\beta, \kappa; \Omega) = 0 \qquad \Leftrightarrow \qquad F_l^{-1}(z, \Omega) = F_r(z, \Omega). \tag{31.35}$$

For example, for the solitary lasers considered in Figure 31.3b and c, $F_l(b_1, \Omega)$ is defined in Equation 31.13, whereas $F_r(b_1, \Omega) = r_2$. In the general case, functions F_l and F_r are defined by a consequent superposition of the sectional transfer matrices $M(\beta, \kappa, \Omega)$ and the left-to-right or right-to-left junction-transfer matrices

$$\mathcal{T}_{j,22}^{-1}\begin{pmatrix} \det \mathcal{T}_j & \mathcal{T}_{j,12} \\ -\mathcal{T}_{j,21} & 1 \end{pmatrix} \qquad \text{or} \qquad \mathcal{T}_{j,11}^{-1}\begin{pmatrix} 1 & -\mathcal{T}_{j,12} \\ \mathcal{T}_{j,21} & \det \mathcal{T}_j \end{pmatrix};$$

see References [23,26,28] for more details.

---

† In the case of nonvanishing $\Delta_\beta = \frac{\beta^+ - \beta^-}{2}$, the transfer matrix in each section S_k should be constructed for $\bar{\beta} = \frac{\beta^+ + \beta^-}{2}$ and later multiplied by the factor $e^{-i\langle\Delta_\beta\rangle_k|S_k|}$ [23].

The calculated optical field function $\Psi(z,t) = (E^+, E^-, P^+, P^-)^T$ can be represented as a superposition of the suitably normalized vector functions $\Theta(\beta, z)$ which are slowly changing with a variation of the propagation factor $\beta(z,t)$:

$$\Psi(z,t) = \sum_{j=1}^{\infty} f_j(t)\Psi_j(\beta(z,t), z). \tag{31.36}$$

Here, $f_j(t)$ is the complex amplitude of the mode, which can denote the mode contribution to the field emission at the laser facet a_k once normalization of mode functions assumes $\Theta_E^-(\beta, a_k) = 1$. According to our notations, index $_1$ denotes the most significant mode having a largest (instant) amplitude $|f|$ or a lowest damping $\Im\Omega$. An increasing index means a decreasing importance of the mode. This numbering does allow us to achieve good approximations of the field function $\Psi(z,t)$ already by low-dimensional truncated mode expansions 31.36.

Calculation of optical modes and expansion of the field function into the modal components can give a broad understanding of different operating regimes in MSLs and explain parameter change-induced transitions between these states observed in simulations and experiments. We have applied our mode analysis for interpretation of experimental observations in different MSLs. Namely, we have explained a stable operation of ring lasers at alternating oscillation or bi- and unidirectional steady state regimes [23]; almost periodically reappearing state transitions and estimation of thermal tuning parameters in master-oscillator power-amplifier device [38,56], DBR laser [14], or ECDL [15]; and strongly asymmetric pulse shapes in QD mode-locked laser [49]. More theoretical examples of our mode analysis can be found in Reference [26].

Steady States:

Any stationary (rotational wave) state of the MSL is determined by an optical mode with a *real* mode frequency

$$(\Psi(z,t), N(z,t)) = \left(\hat{f}\,\Theta(\hat{\beta}, z)e^{i\hat{\omega}t}, \hat{N}(z)\right), \quad \text{where } \Omega(\hat{\beta}) = \hat{\omega} \in \mathbb{R},$$

and $\hat{\beta}(z)$ is a constant in time spatially distributed propagation factor. Let us consider the TW model with sectionally averaged carrier density and neglected nonlinear gain compression given by Equations 31.4, 31.5, 31.14, 31.18, 31.15, and 31.28. In this case, all steady states are fully defined by a set of n_a+2 real numbers $\left(\hat{\omega}, |\hat{f}|^2, \hat{N}_1, \ldots, \hat{N}_{n_a}\right)$, which are a mode frequency, a mode intensity, and sectionally averaged carrier densities within all n_a "active" sections having nonvanishing functions g and $\tilde{n}$. The rotational invariance of the TW model implies freedom in selection of the phase of the complex mode amplitude $\hat{f}$. The set of these real numbers is a root of a nonlinear algebraic system of one complex characteristic equation and n_a real steady-state carrier rate equations:

$$\begin{aligned} &\det \mathcal{M}\left(\beta(\hat{N}), \kappa; \hat{\omega}\right) = 0, \\ &\frac{I_r}{q\sigma_r|S_r|} - \mathcal{R}(\hat{N}_r) - |\hat{f}|^2 \frac{c_0}{n_g} G(\hat{N}_r, \hat{\omega})\langle\left(\Theta_E, \Theta_E\right)\rangle_r = 0, \quad r = 1, \ldots, n_a. \end{aligned} \tag{31.37}$$

Here, the frequency-dependent gain function G is defined in Equation 31.17, whereas the sectional average $\langle\left(\Theta_E, \Theta_E\right)\rangle_r$ can be expressed as a function of $\hat{\omega}$ and $\hat{N}$ [28].

In the case of the single active section, $n_a = 1$, the steady state frequency $\hat{\omega}$ and threshold carrier density $\hat{N}_1$ can be directly found from the characteristic equation, whereas the remaining equation determines the value of $|\hat{f}|^2$. Assume that the single active section S_1 of linear MSL is located on the left side of the device (see Figure 31.1b), and the optical fields within the adjacent passive section S_2 are governed by the simple relations 31.9. For an illustration of this situation, we have considered a three section passive dispersive reflector laser consisting of the active DFB, passive DBR, and another passive phase tuning section in between. Due to the relation 31.35, we can replace the complex characteristic equation by a couple of real-valued equations,

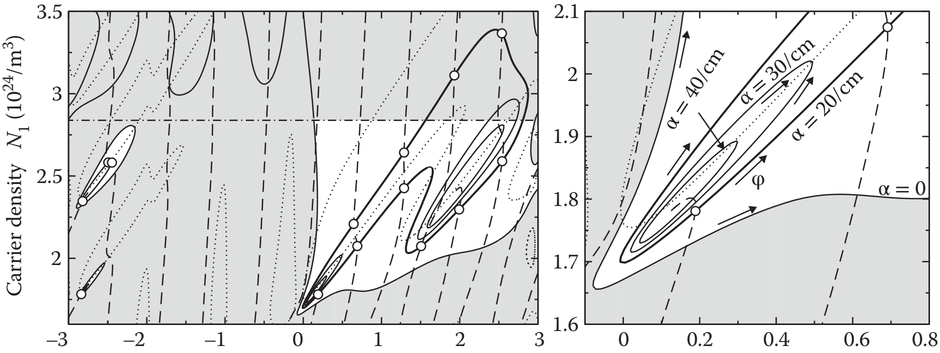
$$F_l^{-1}(a_2,\hat{\omega}) = F_r(a_2,\hat{\omega}) = e^{-\alpha_2|S_2|}e^{i(\varphi-2\hat{\omega}\tau_2)}F_r(b_2,\hat{\omega}) \qquad \Leftrightarrow$$
$$\begin{cases}\tilde{\mathcal{M}}_\alpha(\hat{N}_1,\hat{\omega}) = e^{\alpha_2|S_2|} \\ 2\hat{\omega}\tau_2 - \tilde{\mathcal{M}}_\varphi(\hat{N}_1,\hat{\omega}) = \varphi\end{cases}, \quad \text{where } \tilde{\mathcal{M}}(\hat{N}_1,\hat{\omega}) = \tilde{\mathcal{M}}_\alpha e^{i\tilde{\mathcal{M}}_\varphi} = F_l(a_2,\omega)F_r(b_2,\hat{\omega}) \quad . \tag{31.38}$$

This formulation suggests a simple way for finding the steady states. Namely, each of these equations for fixed parameters α_2 and φ defines one or several curves in frequency ω – carrier threshold N_1 domain, see solid and dashed curves in Figure 31.10. The intersections of these lines determine the steady state pairs $\hat{\omega}, \hat{N}_1$ (hollow bullets in the same figures). It is noteworthy that to any point in the $\omega - N_1$ domain one can attribute a unique triple of loss, phase, and mode power parameters α_2, φ, and $|\hat{f}|^2$. ω and N_1 within the gray shading regions of Figure 31.10 represent the unphysical steady states corresponding to negative damping in the passive section ($\alpha_2 < 0$) and negative mode intensity ($|\hat{f}|^2 < 0$) due to insufficient pumping of the active section.

The fixed level lines of $\tilde{\mathcal{M}}_\alpha$ determined by larger losses $\alpha_2 = 30$ and 40/cm (thin solid-line ellipses located inside of thick solid curves in Figure 31.10) are shrinking toward central points, which are resonances of the solitary DFB laser. Accordingly, the (odd) number of steady states on each ellipse is also reduced. The saddle-node bifurcation that is responsible for creation or annihilation of the steady state pair, occurs at those φ and α_2, where corresponding fixed level lines of $\tilde{\mathcal{M}}_\varphi$ and $\tilde{\mathcal{M}}_\alpha$ become tangent to each other. The last condition formally given by

$$\mathcal{M}_{SN}(\hat{\omega},\hat{N}_1) \overset{def}{=} \partial_\omega\tilde{\mathcal{M}}_\alpha\partial_{N_1}\tilde{\mathcal{M}}_\varphi - \partial_\omega\tilde{\mathcal{M}}_\varphi\partial_{N_1}\tilde{\mathcal{M}}_\alpha = 0$$

is satisfied on the dotted lines of Figure 31.10.



(a) (b)

FIGURE 31.10 Stationary states (frequencies and threshold carrier densities) of a three section DFB laser. Panels (a) and (b) show a global overview and a zoomed-in region close to the minimal threshold mode with $\hat{\omega} \approx 0$. Solid curves represent steady states for an arbitrary φ but only a few fixed α_2. Dashed curves indicate steady states for arbitrary α_2 and fixed $\varphi = 0$. Dotted curve shows positions where saddle-node bifurcations hold. Empty bullets: steady states for $\alpha_2 = 20$/cm and $\varphi = 0$. Dash-dotted line indicates maximal N_1 which can be achieved for considered bias current I. Gray shading corresponds to unphysical states. Small arrows in panel (b) indicate directions of the steady state shift along the fixed loss lines for growing φ. All parameters as in Reference [26].

In general, the interpretation of the steady states for large α_2 (small feedback) is in good agreement with the analysis of the external cavity modes in the Lang–Kobayashi (LK) model of lasers with delayed feedback [18,27]. A decrease of α_2 leads to blowing up and collision of different ellipses. This scenario involves multiple modes of the solitary DFB laser and can be no more explained by the LK model.

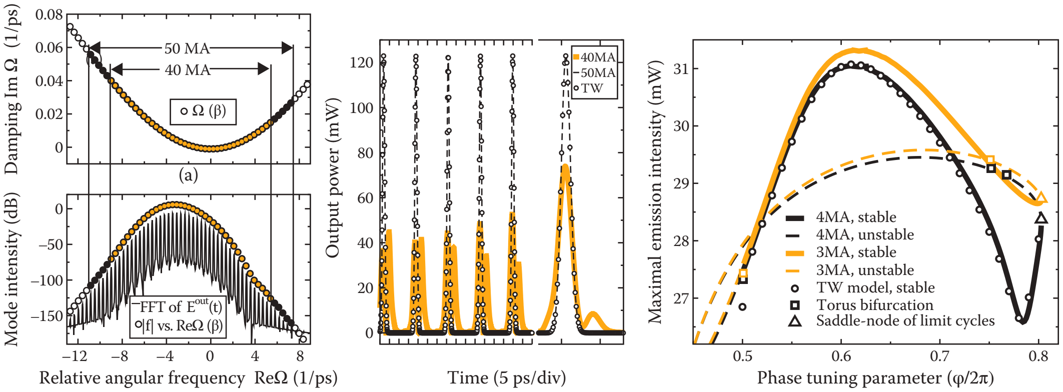
Mode Approximation Systems:

For some MSL devices, the TW model (Equations 31.2 through 31.5, and 31.14, 31.15, 31.28) with sectionally averaged carrier densities, linear gain and index change functions, and neglected gain compression terms can be reduced to the finite-dimensional system of ODEs describing an evolution of q complex mode amplitudes f and real sectionally averaged carrier densities N within n_a active sections of MSL:

$$\begin{aligned} \dot{f}_k &= i\Omega_k(N)f_k + \sum_{l=1}^{q}\left(\sum_{r=1}^{n_a} K^r_{k,l}(N)\dot{N}_r\right)f_l, \quad k = 1,\dots,q; \\ \dot{N}_r &= \frac{I_r}{q|S_r|\sigma_r} - \mathcal{R}(N_r) - \Re\sum_{k,l=1}^{q} L^r_{k,l}(N)f_k^{*}f_l, \quad r = 1,\dots,n_a. \end{aligned} \tag{31.39}$$

This mode approximation (MA) system follows from the substitution of the truncated field expansion (Equation 31.36) into the TW model equations and projection of the resulting field equations onto the linear subspace defined by each of q modes. The nonadjoint nature of the field evolution operator and small but nonvanishing time derivatives of propagation factor $\beta(N)$ imply the appearance of the mode coupling terms $K^r_{k,l}\dot{N}_r$. For the derivation of the MA equations and analytic expressions for carrier and mode frequency Ω-dependent mode-coupling functions, $K^r_{k,l}$ and $L^r_{k,l}$, see Reference [28].

To check the precision of our MA system, we have performed simulations of the TW model and two related MA systems describing the evolution of a mode-locked laser consisting of a saturable absorber and an amplifying section (case of $n_a = 2$). The solid black curve and hollow bullets in Figures 31.11b and c show typical optical spectrum and time trace of the mode-locking pulsations obtained by numerical integrations of the TW model. To determine the most relevant complex mode frequencies $\Omega(N)$



(b) (c) (d)

FIGURE 31.11 Calculated (a) complex frequencies Ω, (b) optical spectra as a Fourier-transformed field $E^{-}(a_1, t)$ (black solid curve) and as a discrete set of mode intensities $|f|^2$ versus $\Re\Omega$ (bullets), and (c) a comparison of the calculated transients of the TW model (bullets) and the reduced ODE systems determined by 40 (solid gray) or 50 (dashed black) optical modes in a two-section mode-locked laser. Full black and small gray bullets in panels (a) and (b) indicate the modes used for the construction of 40MA and 50MA systems. (d) Numerical path following of the stable periodic solution of the TW model (bullets) and periodic orbits of 3MA (gray) and 4MA (black) systems in a three-section phase-controlled mode-beating DFB laser [12,28]. Solid and dashed curves indicate stable and unstable orbits. Empty boxes and triangles denote torus and fold bifurcations, respectively.

(Figure 31.11a) and the coefficients f in the field expansion 31.36 (bullets in panel [b]), we have used the carrier densities $N = (N_1, N_2)$, optical fields E, and polarization functions P obtained as a result of the numerical integration of the TW model. For the construction of the 40MA and 50MA systems, we have used the modes indicated by full black and a bit smaller gray bullets in Figures 31.11a and b. Solid gray and black dashed curves in Figure 31.11c represent the numerical integration of these MA systems. One can see that whereas 40MA system fails to reproduce the stable periodic regime, the 50MA system provides a perfect approximation of the TW model. We note that a significant number of excited optical modes in the example considered above does not allow achieving a low dimensional approximation of the TW model. The number of active modes usually is much smaller in MSLs containing one or more DFB sections. In this case, already three or four appropriately selected optical modes are sufficient for a good approximation of the TW model [7,28].

An integration of the MA system (Equation 31.39) remains a nontrivial task, because for each actual set of carrier densities $N = (N_1, \dots, N_r)$, one should find the corresponding mode frequencies $\Omega_k(N)$, $k = 1, \dots, q$ by solving the characteristic Equation 31.34 numerically. Since the required computation time of the MA systems grows quadratically with the increasing number of modes, one can integrate the TW model faster than the 50MA system. The usefulness of the MA approach starts to be visible when combining our model reduction technique with the numerical continuation and bifurcation analysis tools [29] suited for investigation of nearly arbitrary systems of ODEs. Figure 31.11d presents an example of numerical bifurcation analysis of 3MA (gray) and 4MA (black) systems describing dynamics of the three-section laser consisting of two active DFB sections and a passive phase tuning section in between ($n = 3$ and $n_a = 2$ in this case). Here, solid and dashed curves represent stable and unstable branches of the periodic orbit implied by beating of two closely located resonances, supported by each DFB section. Empty bullets in the same figure represent the continuation of the stable periodic state by direct integration of the TW model. By comparing the bullets and curves, one can see that both MA systems were able to reproduce the stable branch of the periodic orbit, and identify torus and saddle-node bifurcations where this state have lost its stability. The deviation of the solid gray curve from the bullet positions in Figure 31.11d, however, indicates the insufficiency of the 3MA system to reproduce the orbit shape. More detailed analysis of this laser including a continuation of bifurcations in two parameter domain can be found in Reference [28].

31.11 Conclusions

In this chapter, we introduce a hierarchy of TW models describing nonlinear dynamics in individual semiconductor lasers, various MSLs, and coupled laser systems. To simulate these laser devices, we use our software package LDSL-tool, which treats MSLs as a set of differently interconnected laser sections. At the end of the chapter, we introduce several advanced techniques allowing detailed analysis of the model equations. These methods include computation of optical modes, a study of the mode spectra, expansion of electric fields into modal components, a semianalytic location of all steady states of the MSLs, model reduction, numerical continuation, and bifurcation analysis of the reduced system. Altogether, these advanced possibilities of our software tool allow to achieve a thorough understanding of the processes observed both, in the direct integration of model equations and experiments.

32.1 General Principles of Mode Locking, the Important Features of Mode-Locked Semiconductor Lasers, and the Role of Theory and Modeling

In the most general sense, *mode locking* (ML) is a regime of laser operation that involves emitting light in several modes with a time-independent relation between them, i.e., with constant and precisely equidistant frequencies. Usually, the term is used more specifically, referring to what is, rigorously speaking, *amplitude-modulation* (AM) ML, meaning that the phase differences between of adjacent modes are approximately equal. In time domain, this corresponds to the laser's emitting a train of ultrashort optical pulses at a repetition frequency F near the cavity round-trip frequency or its harmonic:

$$F \approx M_{\mathrm{h}} v_{\mathrm{g}}/(2L). \tag{32.1}$$

Here, v_g denotes the group velocity of light in the laser resonator and L is the Fabry–Pérot resonator cavity length. In the case of the ring resonator, $2L$ in Equation 32.1 is substituted by the ring cavity length. The harmonic number M_h corresponds to the number of pulses coexisting in the cavity; in the simplest and most usual case, $M_h = 1$. The pulse duration is then of the order of $2L/(N_M v_g)$, with N_M being the number of lasing modes in the spectrum.

In most cases (some important exceptions will be mentioned below), ML does not occur spontaneously and requires a special laser construction and/or operating conditions. Namely, it is usually achieved either by modulation of the laser net gain at a frequency F or its (sub)harmonic (known as *active* ML) or by exploiting nonlinear properties of the medium to shorten the propagating pulse (known as *passive* ML, PML); in both cases, the pulse shortening mechanism needs to be strong enough to counter the broadening effects of gain saturation and dispersion effectively. PML, in turn, is usually achieved by introducing a saturable absorber (SA) into the laser cavity. The SA both facilitates a self-starting mechanism for ML and, most importantly, plays a crucial role in shortening the duration of the circulating pulses. As a variation of this principle, *refractive index nonlinearities* approximately equivalent in their action to saturable absorption have been intensely studied in the last decades; salient examples are *additive pulse ML* and *Kerr lens ML* in solid-state lasers, see, e.g., Haus (2000) for more detail.

A combination of active and passive methods of ML is known as *hybrid* ML; if the external modulation is in the form of short pulses, the corresponding regime is referred to as *synchronous* ML.

Mode-locked solid-state lasers, often diode pumped, have allowed sub-100 femtosecond pulses to be generated (Brown et al., 2004; Ell et al., 2001; Innerhofer et al., 2003), with peak powers in the range of many kilowatts (partly due to the relatively low repetition rates, typically in the megahertz range or below).

In *semiconductor diode lasers*, the most basic physical mechanisms underlying the generation of short pulses are fundamentally similar to those of other types of lasers, but a number of features are very different, as regards both technology and physics.

From the practical and technological point of view, diode lasers have a number of advantages: They represent the most compact and efficient sources of picosecond and subpicosecond pulses. They are directly electrically pumped, and the bias current can be easily adjusted to determine the pulse duration and the optical power, thus offering, to some extent, electrical control of the characteristics of the output pulses. These lasers also offer the best option for the generation of high-repetition rate trains of pulses, owing to their small cavity size L in Equation 32.1 and hence the large values of F, well into multigigahertz range. Being much cheaper to fabricate and operate than most other types of lasers, ultrafast semiconductor lasers also offer the potential for dramatic cost savings in a number of applications that traditionally use solid-state lasers. The deployment of high-performance ultrafast diode lasers could therefore have a significant economic impact by enabling ultrafast applications to become more profitable and even facilitate the emergence of new applications. At the moment, actual and potential applications of mode-locked lasers include time- and wavelength-multiplexed communications, metrology, biomedical applications, etc.; see Avrutin and Rafailov (2012) for an overview.

From the point of view of physics, which underlies the technology, most of the distinct features of semiconductor lasers, including mode-locked ones, lie in the energy spectrum of semiconductors that consists in continuous bands of energy with relatively high density of states, as opposed to discrete levels in solid-state lasers. Most mode-locked semiconductor lasers operate on fundamental interband transitions (though there has been some work on active ML of intersubband quantum cascade lasers; see, e.g., Revin et al., 2016 and references therein). Semiconductors thus have both a higher gain per unit length (which is one of the reasons of the short cavity length being possible) and a higher nonlinear refractive index than other gain media (the relation between carrier density dependences of gain and refractive index in semiconductor lasers is often quantified via Henry's linewidth enhancement factor α_H that, as discussed below, plays an important role in the theory of ML). The interaction of the pulse with the gain and saturable absorption and the resulting large changes in the nonlinear refractive index lead to significant self-phase modulation, imparting a noticeable *chirp* to the ML pulses, usually up-chirp in the case of passively mode-locked lasers and down-chirp in actively mode-locked ones. This increases the *time-bandwidth product* of the pulse and has been one of the important limitations in obtaining pulse durations of the order of 100 fs *directly* from the diode lasers, with picosecond pulses being the norm. Furthermore, a strong saturation of the gain also results in stabilization of the pulse energy, which limits the average and peak power to substantially lower levels than in vibronic/solid-state lasers. Output average power levels for mode-locked laser diodes are usually between 0.1 and 100 mW, while peak power levels remain between 10 mW and 1 W. Only with additional amplification/compression setups, can the peak power reach the kW level (Kim et al., 2005). Another distinction of semiconductor lasers is that the typical scales of carrier recombination times in semiconductor materials are of the order of hundreds of picoseconds, comparable to the ML repetition time, leading to a rich variety of dynamic instabilities in the laser behavior, some of which, as will be discussed later, determine the *lower* limit for stable ML frequency (and therefore the longest possible laser cavity) for given material parameters.

There has been a large variety of semiconductor laser designs used for ML, from external cavity ones operating at sub-GHz rates to monolithic ones reaching terahertz repetition frequencies (Avrutin et al., 2000), with laser design strongly affecting, not just the laser performance, but the relative importance of the underlying physical effects in determining this performance.

This combination of practical promise, versatility, and scientific challenge has made mode-locked semiconductor lasers an important topic of research for more than two decades; they have arguably attracted considerably more attention than all other methods of ultrashort pulse generation taken together. The most recent years have seen considerable progress in both improving the theoretical understanding of ML in semiconductor lasers and using this understanding to improve their performance in terms of power, pulse duration/chirp, stability, repetition rates accessible, and integrability issues.

This progress has been partly summarized in previous reviews on ML in semiconductor lasers, with some of them (Avrutin et al., 2005) explicitly concentrating on modeling and simulation and others (Avrutin et al., 2000; Avrutin and Rafailov, 2012) paying significant attention to it. Here, we shall partly follow the logic and layout of the previous paper (Avrutin and Rafailov, 2012), but will attempt to present a more modern perspective and cover the recent results by ourselves and other researchers.

32.2 ML Techniques in Laser Diodes: The Main Features

The main advantages of ML over other methods of generating ultrafast pulses by laser diodes are the higher repetition rate pulses and shorter pulse durations. To realize these advantages to the fullest, a variety of ML techniques and device structures have been investigated and optimized (Vasil'ev, 1995). All three main forms of ML—active, passive, and hybrid—have been extensively studied for semiconductor lasers.

Purely *active* ML in a semiconductor laser can be achieved by direct modulation of the gain section current with a frequency very close to the pulse repetition frequency in the cavity or to a subharmonic of this frequency. Alternatively, an electroabsorption segment of a multielement device can be modulated to produce the same effect, or a separate modulation section introduced. The main advantages of active ML techniques are the resultant low jitter (essentially determined by the electrical generator imposing the modulation) and the ability to synchronize the laser output with the modulating electrical signal, which is a fundamental attribute for optical transmission and signal processing applications. However, high repetition frequencies are not readily obtained through directly driven modulation of lasers because fast microwave modulation, particularly of current, becomes progressively more difficult with increase in frequency.

PML of semiconductor lasers typically utilizes an SA region in the laser diode. Upon start-up of laser emission, the laser modes initially oscillate with relative phases that are random; in other words, the temporal radiation pattern consists of irregular bursts. If one of these bursts is energetic enough to provide energy, or more accurately fluence (energy per unit area) of the order of the saturation fluence of the absorber, it will partly bleach the absorption. This means that around the peak of the burst where the intensity is higher, the loss will be smaller, while the low-intensity wings become more attenuated. The pulse generation process is thus initiated by this family of intensity spikes that experience lower losses within the absorber carrier lifetime. The dynamics of absorption and gain play a crucial role in pulse shaping. In steady state, the unsaturated losses are higher than the gain. When the leading edge of the pulse reaches the absorber, the loss saturates more quickly than the gain, which results in a net gain window, as depicted in Figure 32.1. The absorber then recovers from this state of saturation to the initial state of high loss, thus attenuating the trailing edge of the pulse. It is thus easy to understand why the saturation fluence and the recovery time of the absorber are of primary importance in the formation of mode-locked pulses.

In practical terms, the SA can be monolithically integrated into a semiconductor laser by electrically isolating one section of the device (Figure 32.2a). By applying a reverse bias to this section, the carriers photogenerated by the pulses can be more efficiently swept out of the absorber, thus enabling the SA to recover more quickly to its initial state of high loss. An increase in the reverse bias serves to decrease the

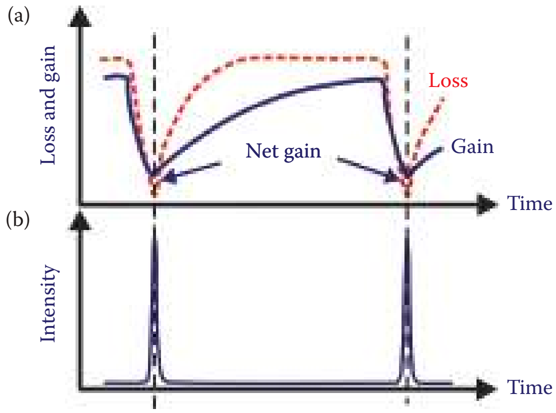

FIGURE 32.1 Schematic illustration of the mechanism of passive mode locking: (a) the loss and gain dynamics that lead to (b) pulse generation.

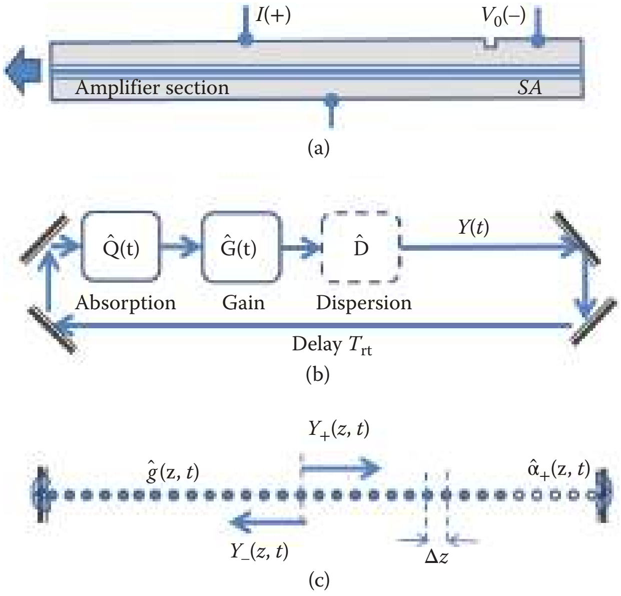

FIGURE 32.2 Schematic of (a) the simplest design of an edge-emitting passively mode locked laser, and its representation in (b) the lumped model of Sections 32.3.1 and 32.3.3, and (c) the traveling-wave model (TWM) of Section 32.3.4.

absorber recovery time, which will have the effect of further shortening the pulses (a faster absorber may act to shorten the trailing as well as the leading edge of the pulse). Alternatively, an SA can also be implemented through ion implantation on one of the facets of the laser, thus increasing the nonradiative recombination (Delpon et al., 1998).

PML provides the shortest pulses achievable by all three techniques, albeit at the expense of somewhat larger pulse jitter and radio frequency (RF) linewidth than in active or hybrid ML. It can be intuitively understood in the following way: Active ML generates a fixed AM of the gain while PML induces a modulation that is proportional to the pulse energy, meaning potentially more efficient mode coupling. Besides, the absence of an RF source simplifies the fabrication and operation considerably. PML also allows for higher pulse repetition rates than those determined solely by the cavity length, by means of harmonic ML ($M_h > 1$ in Equation 32.1; some means of achieving this are considered in more detail below).

Hybrid ML can be achieved by applying RF modulation either to gain or to the SA section. It has been shown, however, that the more efficient method is the latter one, in which case the SA doubles as an electroabsorption modulator. In this case, the pulse generation may be seen as initiated by a modulation provided by the RF signal, while further shaping and shortening are assisted by the SA. This process results in high-quality pulses, synchronized with an external source.

32.3 Theoretical Models of ML in Semiconductor Lasers

Any model of mode-locked laser dynamics should account for pulse shortening by modulation (active/hybrid ML) and/or saturable absorption (passive/hybrid ML) and for pulse broadening by saturable gain and cavity dispersion (including gain/loss dispersion and group velocity/phase dispersion), as discussed above. In addition, if spectral properties are to be accounted for accurately, self-phase modulation needs to be included in the model. In this section, we shall cover general principles of the possible approaches, concentrating on the relatively recent advances in ML theory that have underpinned the significant progress in understanding the details of ML dynamics.

32.3.1 Small-Signal Time-Domain Models and Self-Consistent Pulse Profile

Conceptually the simplest, and historically the oldest, models of mode-locked lasers are *time-domain lumped models* (Figure 32.2b), based on the approximation that the pulsewidth is much smaller than the repetition period, and treating a hypothetic ring laser with unidirectional propagation. The amplification and gain/group velocity dispersion (GVD), which in reality are experienced by the pulse simultaneously, may then be approximately treated in two independent stages. This allows the representation of the distributed amplifier in the model by a lumped *gain element* performing the functions of amplification and self-phase modulation. Mathematically, this element can be described by a nonlinear integral or integro-differential operator acting on the complex pulse shape function (complex slow amplitude) $Y(t)$, t being the *local* time of the pulse. The model was originally designed for solid-state and gas lasers, whose long lengths make for a round-trip time many orders of magnitude longer than the pulse duration, so separate timescales are introduced explicitly for the pulse (the short timescale) and relaxation period between pulses (the long timescale).

The gain operator takes the form

$$\hat{G}Y(t) = \exp\left(\frac{1}{2}(1 - i\alpha_{Hg})G(t)\right) Y(t), \tag{32.2}$$

with α_{Hg} the Henry linewidth enhancement factor in the amplifier and $G(t) = \Gamma \int g(z - v_g t, t)dz$ the total gain integrated over the length of the amplifying region (v_g being the group velocity of light). Further analytical progress can be made by using spatially resolved rate equations for the carrier density N_g in the gain region $\frac{\mathrm{d}N_{\mathrm{g}}(z,t)}{\mathrm{d}t} = -g(N_{\mathrm{g}})\frac{P(z,t)}{\hbar\omega A_x} - \frac{N_{\mathrm{g}}}{\tau_{\mathrm{g}}}$, where P is the power of light, $\hbar\omega$ the photon energy, A_x the cross section of the optical beam (mode) in the gain section, and τ_{g} the gain recovery time. A number of approximations are then made. Those involve neglecting dispersion and fast nonlinearities, assuming (which is a safe assumption in semiconductor active media) that $\tau_{\mathrm{g}} \gg \tau_{\mathrm{p}}(\tau_{\mathrm{p}}$ being the pulse duration), so gain relaxation during the pulse can be neglected, and assuming a linear dependence of gain on the carrier density: $\mathrm{g}(N_{\mathrm{g}}) \approx \sigma_{\mathrm{g}}(N_{\mathrm{g}} - N_{\mathrm{tr}}), \sigma_{\mathrm{g}} = \mathrm{dg}/\mathrm{d}N$ being the gain cross section (the derivative of the gain on the carrier density) and N_{tr} the transparency carrier density. With these assumptions, an approximate explicit expression for $G(t)$ on the short timescale commensurate with the pulse duration can be obtained. In the case of $G \ll 1$, it takes the form

$$G(t) = G_{-} \exp(-U(t)/U_{\mathrm{g}}). \tag{32.3}$$

Here, $U(t) = \int_{-\infty}^{t} P(t')\mathrm{d}t' = v_{\mathrm{g}}\hbar\omega A_X \int_{-\infty}^{t} |Y(t')^2\mathrm{d}t'$ is the pulse energy up to the time t, $G_{-} = \Gamma \int g(z, t \to -\infty)\mathrm{d}z$ is the total amplification in the gain element at the time before the arrival of the pulse, and

$$U_{\mathrm{g}} = \frac{\hbar\omega A_X}{\sigma_{\mathrm{g}}} \tag{32.4}$$

is the saturation energy of the amplifier.

The SA, if any, is also considered as a lumped element, described, in the simplest case, by an operator similar to Equation 32.3:

$$\hat{\mathrm{Q}}_{\mathrm{S}} Y(t) = \exp\left(-\frac{1}{2}(1 - i\alpha_{\mathrm{H}\alpha})Q_{\mathrm{S}}(t)\right) Y(t), \tag{32.5}$$

with the absorber linewidth enhancement factor $\alpha_{\mathrm{H}\alpha}$, and the dimensionless slow saturable absorption $Q_{\mathrm{S}} = \Gamma \int \alpha(z - v_{\mathrm{g}}t, t)\mathrm{d}z$, in the ideal slow absorber approximation and with $Q \ll 1$, given by

$$Q_{\mathrm{S}}(t) = Q_{-} \exp(-U(t)/U_{\alpha}). \tag{32.6}$$

Here, again, the total initial absorption $Q_{-} = \Gamma \int \alpha(z, t \to -\infty)\mathrm{d}z$, and the absorber saturation energy is

$$U_{\alpha} = \frac{\hbar\omega A_{X\alpha}}{\sigma_{\alpha}}, \tag{32.7}$$

where $\sigma_{\alpha} = |\mathrm{d}\alpha/\mathrm{d}N|$ is the SA cross section, and, depending on the construction, the cross section of the beam $A_{X\alpha}$ in the SA may be different from that of the amplifying section; as shown below, it is usually advantageous to have $A_{X\alpha} < A_X$.

Equation 32.6 is obtained in the same way as Equation 32.3 by using the spatially resolved rate equation for the carrier density in the absorber region $\frac{\mathrm{d}N_{\alpha}(z,t)}{\mathrm{d}t} = \alpha(N_{\alpha})\frac{P(z,t)}{\hbar\omega A_{X\alpha}} - \frac{N_{\alpha}}{\tau_{\alpha}}$, with τ_{α} the absorber relaxation time and, and making the same assumptions: assuming a linear dependence of the absorption on the SA carrier density $\alpha(N_{\alpha}) \approx \alpha_0 - \sigma_{\alpha}N_{\alpha}$, with α_0 the unsaturated absorption, and neglecting the SA relaxation during the pulse. The latter is known in the theory of ML as *the ideal slow absorber* approximation, meaning that the SA recovery time τ_{α}, like that of gain τ_{g}, needs to be much longer than the pulse duration τ_{p}. However, while the assumption $\tau_{\mathrm{g}} \gg \tau_{\mathrm{p}}$ is readily fulfilled in semiconductor lasers ($\tau_{\mathrm{g}} \sim 1$ ns), the assumption $\tau_{\alpha} \gg \tau_{\mathrm{p}}$ may be strained ($\tau_{\alpha} \sim 10$ ps), which may necessitate some modifications to the model, described below, to improve its accuracy.

Absorption in semiconductor SAs tends, in addition, to contain a subpicosecond component that acts as a "fast" SA (recovery time $\ll \tau_p$) even for short pulses ($\tau_p \sim 1$ ps), typically generated by semiconductor lasers. Some lumped time-domain models (Haus and Silberberg, 1985) also include "fast" effects in the SA (SA nonlinearities) as an equivalent fast absorber characterized by an operator $\hat{Q}_F Y(t) = \exp\left(-\frac{1}{2}Q_F(t)\right) Y(t)$ and with an equivalent absorption:

$$Q_F(t) = Q_{iF}(1 - \varepsilon_\alpha |Y(t)|^2). \tag{32.8}$$

Then, the total absorption is

$$\hat{Q}Y(t) = \hat{Q}_S\hat{Q}_F Y(t). \tag{32.9}$$

Gain nonlinearities may, in principle, be included in the same way, although a more accurate account of dynamics may be preferable, particularly in the case of quantum dot (QD) materials.

Finally, in the traditional form of a lumped model, the dispersion of material gain and refractive index, together with any artificial dispersive elements present in the cavity, such as a distributed Bragg reflector (DBR), are combined in a lumped *dispersive element*. In the frequency domain, its effect on the pulse may be written as

$$\hat{D}Y^T(\omega) = e^{i\varphi_0}\left[\frac{1}{1 - i(\omega - \omega_p)/\gamma} + D(\omega - \omega_0)^2\right] Y^T, \tag{32.10}$$

where Y^T is the Fourier transform of the complex pulse shape $Y(t)$, ω_p and $\gamma \ll \omega_p$ are the peak frequency and the bandwidth of the dispersive element (defined by the gain curve of the amplifier and the frequency selectivity of a grating element, if it is present in the cavity), and ω_0 is the reference frequency as in the analysis of amplifiers. The value of ω_p may change during the pulse (due to gain curve variation with carrier density, most importantly the gain peak shift); this modifies the dispersive operator (Leegwater, 1996), although in the majority of papers on the subject, the effect is not included. ϕ_0 denotes the phase shift introduced by the element and D is the equivalent dispersion (including the GVD of the passive waveguide and the effective dispersion of the external grating element, if any). To rewrite the operator (Equation 32.10) in the time domain, one may expand the first term around the reference frequency ω_0 noting that $|\omega_p - \omega_0| \ll \omega_0$. Then, after a standard transformation, $(\omega - \omega_0)Y^T \div id/dt\ Y$ (Equation 3.7) becomes a differential operator; if the exponential is expanded keeping the first two terms, the operator is reduced to second order.

The dynamics of ML process are then described by cascading the operators and setting:

$$Y_{i+1}(t) = \left(\sqrt{\kappa}\hat{G}\hat{Q}\hat{D}\right) Y_i(t), \tag{32.11}$$

where i is the number of the pulse round-trip (determining the "slow" evolution of the ML pulse), the time t is on the fast timescale commensurate with the pulse duration, and the dimensionless parameter $\kappa < 1$ introduces the total (integrated) unsaturable intensity losses in the cavity, both distributed and due to outcoupling. The model reflects the balance of the main processes affecting the pulse in a mode-locked laser in that the saturable absorption operator $\hat{Q}$ acts to narrow the pulse down, whereas the gain saturation $\hat{G}$ and the dispersion operator $\hat{D}$ act to broaden it. The *stationary* ML equation is thus obtained by writing out the condition that the broadening and narrowing cancel each other, and the shape of the pulse is conserved from one repetition period to the next. In the operator notation introduced above, this means

$$\left(\sqrt{\kappa}\hat{G}\hat{Q}\hat{D}\right) Y(t) = e^{i\delta\psi} Y(t + \delta T), \tag{32.12}$$

where δT is the shift of the pulse or detuning between the repetition period and the round-trip of the "cold" cavity (or its fraction in case of locking at harmonics of the fundamental frequency), and $\delta\psi$ is the optical phase shift induced by the round-trip. In between the pulses, on the slow timescale commensurate with the round-trip time, gain and SA are allowed to recover with their characteristic relaxation times, according to the rate equation for carrier density with $S = 0$. This allows one to calculate the values of gain and saturable absorption at the onset of the pulse, given the pulse energy and repetition period (the only point at which this latter parameter enters a lumped time-domain model).

In the approximation of no dispersion ($\widehat{D} = 1$), the broadening of the pulse by gain saturation alone in the lumped model cannot compensate for the shortening by the absorption. The model in this approximation thus predicts the steady output in the form of a series of *infinitely short* (delta function-like) pulses; neither the pulse shape nor the duration can be analyzed in this approximation. However, it is possible to determine the total pulse *energy* and also analyze the stability of the solutions by requiring that net gain both immediately before the pulse and immediately after the pulse is smaller than one that translates into

$$\begin{aligned} G_- - Q_- - \ln\kappa &< 0 \\ G_+ - Q_+ - \ln\kappa &< 0. \end{aligned} \tag{32.13}$$

Here G_-, Q_- are the total (integrated) gain and absorption immediately before the pulse, and G_+, Q_+ are the values immediately after the pulse. This is known as New's theory of ML (strictly speaking, G. New's original 1970s paper (New, 1974) related to nonsemiconductor lasers in which $\ln(1/\kappa) \ll 1$; however, Equation 32.13 is also applicable in the generalized version of the theory proposed by Vladimirov et al. (2004) and Vladimirov and Turaev (2005) and covered in more detail below).

Analytical approximations for the *pulse shape and duration* have been originally obtained in the case of weakly nonlinear analysis, that is to say if the pulse energy is smaller than $U_{\mathrm{G,A}}$ and the gain and loss (saturable and unsaturable) during one round-trip are small ($\ln(1/\kappa), G, Q \ll 1$). Then, the exponentials in the formulas for the gain and loss operators may be expanded in Taylor series keeping terms up to the second order in Equations 32.3 and 32.6 (weak to moderate saturation of gain during the pulse):

$$\exp\left(-\frac{U(t)}{U_{\mathrm{g},\alpha}}\right) \approx 1 - \frac{U(t)}{U_{\mathrm{g},\alpha}} + \frac{1}{2}\left(\frac{U(t)}{U_{\mathrm{g},\alpha}}\right)^2, \tag{32.14}$$

and to the first order in Equations 32.2 and 32.5 (small gain and loss):

$$\exp\left(\frac{1}{2}(1 - i\alpha_{\mathrm{Hg}})G(t)\right) \approx 1 + \frac{1}{2}(1 - i\alpha_{\mathrm{Hg}})G(t); \exp\left(-\frac{1}{2}(1 - i\alpha_{\mathrm{H}\alpha})Q(t)\right) \approx 1 - \frac{1}{2}(1 - i\alpha_{\mathrm{H}\alpha})Q(t) \tag{32.15}$$

(the accuracy of the model can be improved by expanding these equations, too, to the second rather than first order).

Then, following the route pioneered by H. Haus in the first papers on ML in lasers of an arbitrary type (Haus, 1975) and later adapted specifically to diode lasers (Koumans and vanRoijen, 1996; Leegwater, 1996), the ML Equation 32.12 is rewritten as a complex second-order integro-differential equation known as the master equation of ML, which permits an analytical solution of the form

$$Y(t) = Y_0 \exp(i\Delta\omega t)\left(\cosh\frac{t}{\tau_{\mathrm{p}}}\right)^{-1+i\beta}, \tag{32.16}$$

known as the *self-consistent profile* (SCP). The corresponding theoretical approach is known as the SCP, or Haus's ML theory, as applied to semiconductor lasers (in lasers of other kind, for instance, the account for both slow and fast absorbers is typically not necessary). Assembling the terms proportional to the zeroth, first, and second power of $\tanh(t/\tau_{\mathrm{p}})$ in the ML equation, one obtains three complex, or six real, transcendental algebraic equations (Koumans and vanRoijen, 1996; Leegwater, 1996) for six real variables: pulse amplitude $|Y_0|$, duration measure τ_p, chirp parameter β, optical frequency shift $\Delta\omega = \omega - \omega_0$, repetition period detuning δT, and phase shift arg (Y_0) (which is not a measurable parameter, so in reality there are five meaningful equations). These equations, being nonlinear and transcendental, generally speaking, cannot be solved analytically, but still allow for some insight into the interrelation of pulse parameters. For example, it can be deduced (Leegwater, 1996) that the pulse duration may be considerably shortened by the presence of a fast (instantaneous) component in the saturable absorption and the achievable pulse durations are estimated about 10 times the inverse gain bandwidth, decreasing with increased pulse energy.

By requiring the net small-signal gain before and after the pulse to be negative (Equation 32.13) so that noise oscillations are not amplified, the SCP approach also allows the parameter range of the stable ML regime to be estimated.

Some conclusions from the SCP approach are borne out by more precise models (see below). In particular, it highlights the role of *the gain-to-absorber saturation energy ratio*:

$$s = \frac{U_g}{U_\alpha} = \frac{\sigma_\alpha A_{Xg}}{\sigma_g A_{X\alpha}} \tag{32.17}$$

in the ML laser performance. A minimum value of $s > 1$ is needed to achieve ML at any range of parameters at all and the range of stable ML operation broadens with an increased s. Colliding pulse mode-locked configurations, linear or ring, increase the pulse stability and also lead to shorter pulses by increasing the parameter s.

The SCP model also predicts, correctly, that increasing the dispersion parameter D also increases the parameter range for ML, at the expense of broadening the pulses, and that the slight variation of the frequency F around the estimate (Equation 32.1) shows a minimum in its dependence on current or unsaturated gain.

When applied more quantitatively, however, the SCP model is not too accurate and cannot adequately describe details of pulse shape and spectral features. Indeed, the pulse shape given by the expression (Equation 32.16) is always symmetric, which, in general, needs not, and often is not, the case in practice. Nor are the dynamic regimes of ML faithfully reproduced by the classic SCP model. The reason for this is a large number of approximations involved in the SCP approach, which have been progressively removed by various researchers at the expense of making the model more complex and, in some cases, requiring numerical rather than semianalytical analysis of the pulse profile, even if the model is still lumped.

First, achieving the SCP requires that the relaxation of gain and absorber during the pulse is negligible so that the gain and absorber operators can be written in the form of Equations 32.3 and 32.6. As mentioned above, this is a safe assumption in semiconductor lasers as regards gain media, but not necessarily the SA. The obvious upgrading to the model is then to include the dynamics of the saturable absorption Q by a characteristic recovery time τ_α. If at the same time we abandon the approximation $Q \ll 1$, then the necessary equation will take the form

$$\begin{gathered} \frac{\mathrm{d}Q(t)}{\mathrm{d}t} = -X(Q)Q\frac{P(t)}{U_\alpha} - \frac{Q_0 - Q}{\tau_\alpha}; \\ X(Q) = \frac{1 - \exp(-Q)}{Q}. \end{gathered} \tag{32.18}$$

Here, $Q_0 = \alpha_0 - L_\alpha$ (L_α being the absorption region length) is the unsaturated total absorption (at repetition periods $T_{\mathrm{rep}} \gg \tau_\alpha$, $Q_- = Q_0$), and X is the geometric factor that stems from averaging the absorption over the length of the absorber area for traveling-wave absorption (in the case of small absorption ($Q_0, Q \ll 1$) treated above, we obtain a constant $X = 1$).

Equation 32.18 is then used with Equation 32.5 instead of Equation 32.6, which it obviously reproduces in the limiting case of $X = 1$, and $\tau_\alpha \gg \tau_p$, or $\tau_\alpha \to \infty$ on the short timescale $t \sim \tau_p$. Unfortunately, even this apparently minor modification to the model means that a closed-form solution in the form of Equation 32.16 is no more possible even with $Q_0, Q \ll 1 (X = 1)$, and the iteration-type procedure (Equation 32.11) has to be repeated numerically until a steady-state profile that satisfies Equation 32.12 is found.

Studies with such a modified SCP model found that even with $X = 1$ in Equation 32.18 (small gain/absorption case) and even with absorber recovery times a few times greater than the pulse duration, the finite τ_α makes some difference to the results, noticeably shortening the pulse, making its shape less symmetric, and affecting boundaries of stable ML regime (Dubbeldam et al., 1997).

32.3.2 Frequency and Time-Frequency Treatment of ML and Dynamic Modal Analysis

An approach conceptually alternative to the time-domain analysis of ML, but to an extent sharing the small-signal nature of the model discussed above, is offered by the technique of modal analysis, static or dynamic (as in Avrutin et al., 2003 and references therein and also in Nomura et al., 2002 and Renaudier et al., 2007). In this approach, instead of analyzing the pulse shape dynamics, a modal decomposition is used and the dynamics of mode amplitudes and phases are analyzed. The advantage of the modal expansion is that the time steps can be much longer than in the spatially distributed models of ML (such as the ones described the following section). Indeed, the stiffness of the dynamics in the modal approach is governed by the temporal evolution of the modal amplitudes, and as PML consists in a steady-state regime for those, one foresees that a modal representation of PML may give rise to smooth solutions—this indeed was shown to be the case (Avrutin et al., 2003). In comparison, spatially distributed models naturally need the time step to be much shorter than the pulsewidth, as discussed in more detail in the following section. Besides, the number of variables can be smaller in the modal analysis, particularly in the case of laser designs with a spectrally selective element where only a few modes are excited, making this approach particularly efficient in analyzing, say, long-scale dynamics of external locking of DBR hybridly mode-locked lasers. It also has the logical advantage of describing steady-state ML as a steady-state solution and, conceptually, allows considering the emergence of stable PML as an order–disorder phase transition in a dissipative system, highlighting the fundamental physical features of PML in addition to its technological implications. Frequency domain analysis can be used as supplementary to time-domain models for some specific problems, as for example the analysis of harmonic operation in a coupled-cavity structure (Yanson et al., 2002), where it actually gives some analytical insight into the modal selectivity of the cavity. Frequency, or time-frequency, modal expansion-based approach to ML is also extremely useful (Kim and Lau, 1993) for analyzing the noise and linewidth properties of the ML signal, as the noise can be seen as exciting higher order *supermodes* (combination of modes) in addition to the fundamental order supermode that is actually realized in ML.

However, the modal expansion approach has a major intrinsic limitation in that it relies on the inherent assumption of weak to modest nonlinearity and modulation, meaning that the results obtained using this method agree reasonably well with time-domain simulations only for the case of high ML frequencies, typically above 100 GHz (short or harmonic cavities) and/or at relatively small currents above threshold. Large-signal instabilities, such as the chaotic leading edge instability, are not predicted accurately, and the accuracy of the frequency-domain models at high amplitudes cannot be guaranteed. In addition, finding the modal structures of complex multisection photonic devices can be cumbersome. Therefore, though the frequency and time-domain analysis of ML originally was introduced approximately simultaneously (reflecting the two major representations of ML, the sequence of periodic pulses and a comb of locked modes), in the context of semiconductor lasers the work on frequency-domain models remains limited. Instead, theoretical progress has been mainly associated with the time-domain models, as they permit a large-signal approach (large modulation of population inversion, or alternatively large nonlinearity) that we cover in the next sections.

32.3.3 Large-Signal Time-Domain Approach and Delay-Differential Equation Model

Both the assumption of weak to moderate pulse saturation during the pulse and, even more so, that of small gain and absorption per pass, as used in small-signal time-domain models discussed in Section 32.3.1, may become even more tenuous in semiconductor lasers than the assumption of an ideally slow absorption—in fact, in edge-emitting lasers, the small-gain assumption is almost always completely inapplicable since at least one of the laser facets is usually uncoated (or even AR-coated to reduce the reflectance to 0.05%–0.1%) to increase the output power, so the outcoupling losses are by necessity significant, making for large gain per pass even with small saturable absorption. Then, it makes sense to abandon the expansions (Equations 32.14 and 32.15) in the fully numerical procedure and use the full exponential form of Equations 32.2 through 32.8, as well as the more accurate full expression for X in Equation 32.18, thus moving from a small-signal SCP model to a *large-signal iterative model* (see, e.g., Khalfin et al., 1995). This also means that the fast nonlinearities of gain and absorption, and possibly part of the dispersion, may be included directly into the gain and absorber operators.

Even in its large-signal form and with the finite absorber (and gain, if necessary) relaxation time taken into account, the iterative procedure (Equation 32.11) is still somewhat artificial in that it requires a trial pulse shape to start with, and explicitly separates the timescale into the short timescale of the pulse and the long timescale of the repetition period. Moreover, if the time window of the pulse is taken as much smaller than the repetition period (which is the standard thing to do if the repetition period is much longer than the pulse), any instabilities related with secondary pulses arising far away from the main pulse may be missed by the model. In semiconductor lasers, neither of these assumptions is well justified, as the pulse may be only about an order of magnitude shorter than the repetition period, so that the separation of scales is not as justified as in lasers of other types, and the chaotic instabilities with several competing pulse trains are a very real threat.

An elegant solution to these modeling limitations is offered in the form of the most sophisticated and the most realistic of the lumped models of mode-locked lasers. In this form of the lumped approach, the two different scales for pulse analysis are, in general, abandoned, and the iteration procedure (Equation 32.11) is substituted by a *delay* one. In a general form, this procedure may be written as

$$Y(t) = \left(\sqrt{\kappa}\hat{\mathrm{G}}\hat{\mathrm{Q}}\hat{\mathrm{D}}\right) Y(t - T_{\mathrm{RT}}), \tag{32.19}$$

where T_{RT} is again the round-trip of the cold cavity, and t is still the local time of the pulse.

A particularly useful form of this model is obtained if the dispersion operator $\hat{D}$ is expanded as a differential one. An efficient form of such an expansion has been derived by Vladimirov et al. (Vladimirov et al., 2004; Vladimirov and Turaev, 2005) who showed that for a bandwidth limiting element with a Lorentzian spectrum similar to Equation 32.10:

$$\hat{\mathrm{D}} \cdot Y^{\mathrm{T}}(\omega) = \left[\frac{1}{1 - i(\omega - \omega_{\mathrm{p}})/\gamma}\right] Y^{\mathrm{T}} \tag{32.20}$$

(i.e., neglecting GVD), assuming without much loss of generality that the peak gain frequency ω_{p} coincides with one of the laser resonator modes, and taking it as the reference optical frequency, we can rewrite Equation 32.19 as

$$Y(t) = -\gamma^{-1}\frac{\partial Y(t)}{\partial t} + \left(\sqrt{\kappa}\hat{\mathrm{G}}\hat{\mathrm{Q}}\right) Y(t - T_{\mathrm{RT}}). \tag{32.21}$$

Equation 32.21 is a delay-differential one, and the model thus becomes the *delay-differential equation*, or DDE, *model* of ML in semiconductor lasers. The development of this model has been arguably the greatest advance in the theoretical analysis of mode-locked lasers since the original papers by Haus and New (of which it is a rigorous generalization and which it reproduces in limiting cases). It allows a full self-contained treatment of mode-locked operation, including a possibility of some (if by necessity limited) analytical progress with a platform for a full large-signal numerical analysis, which gives a complete, and qualitatively correct (if not necessarily completely accurate), picture of all possible regimes of ML laser dynamics and allows a number of important trends to be identified. Therefore, we shall present it here in some detail, following the original papers (Vladimirov et al., 2004; Vladimirov and Turaev, 2005).

The operators $\hat{\mathrm{G}}$ and $\hat{\mathrm{Q}}$ can be calculated using Equations 32.2 through 32.6 (in this version of the DDE model, no fast absorption is present); the integrated absorption Q is found in Equation 32.18, and for the integrated gain G, a similar equation is written. Assuming that the pulse in the unidirectional cavity treated by the model passes the absorber before the amplifier, the equation takes the form

$$\frac{\mathrm{d}G(t)}{\mathrm{d}t} = -\left[\exp\left(G(t)\right) - 1\right]\exp(-Q(t))\frac{P(t)}{U_\mathrm{g}} + \frac{G_0 - G(t)}{\tau_\mathrm{g}}. \tag{32.22}$$

Here, G_0 is the unsaturated gain determined by the pumping conditions.

Equations 32.21, 32.18, and 32.22 are a closed system suitable for a detailed numerical simulation of both stationary and dynamic behavior of PML. They can also be fairly easily adapted to allow numerical analysis of *hybrid* ML behavior. As shown in Vladimirov and Turaev (2005), the DDE model also allows for significant *analytical* progress, similar to one achieved with classical New's and Haus's models as described above, but for a more general case of large single-pass gain and absorption, more relevant for most semiconductor laser constructions than the classical SCP. In the analytical procedure, the slow absorption and gain approximation have to be reintroduced, and the slow (relaxation of gain and absorption between pulses) and fast (evolution during the pulse) stages of laser dynamics are, as in the traditional SCP model, treated separately. Considering the slow stage results in equations connecting the gain and absorption before and after the pulse, we get

$$G_- = G_0 - (G_0 - G_+)\exp(-T_\mathrm{RT}/\tau_\mathrm{g}), \tag{32.23}$$

and

$$Q_- = Q_0 - (Q_0 - Q_+)\exp(-T_\mathrm{RT}/\tau_\alpha). \tag{32.24}$$

At the fast stage, as usual in the theory of short pulses in lasers and amplifiers, the relaxation terms are omitted, and so Equations 32.18 and 32.22 take the form

$$\frac{\mathrm{d}G(u)}{\mathrm{d}u} = -\left[\exp\left(G(u)\right) - 1\right]\exp(-Q(u)); \quad \frac{\mathrm{d}Q(u)}{\mathrm{d}u} = -s\left(1 - \exp\left(-Q(u)\right)\right), \tag{32.25}$$

where u is the dimensionless energy within the pulse, $u(t) = U(t)/U_\mathrm{g}$, and $U(t) = \int_{-\infty}^{t} P(t')\mathrm{d}t' = v_\mathrm{g}\hbar\omega A_{X\mathrm{g}}\int_{-\infty}^{t}|Y|^2(t')\mathrm{d}t'$. Introducing $u_\mathrm{p} = U_\mathrm{p}/U_\mathrm{g}$, $U_\mathrm{p} = U(t \to \infty)$ as the total dimensionless pulse energy (the time of minus infinity on the short timescale meaning the time before the pulse, and plus infinity, covering the entire time of substantial pulse energy, i.e., the entire pulse duration), one can integrate Equation 32.25 to get another set of equations connecting the prepulse and postpulse gain and absorption:

$$Q_+ = Q(u_\mathrm{p}) = \ln\left[1 + \exp(-su_\mathrm{p})(\exp(Q_-) - 1)\right], \tag{32.26}$$

$$G_+ = G(u_\mathrm{p}) = -\ln\left[1 - \frac{1 - \exp(-G_-)}{\left[\exp(-Q_-)\left(\exp(su_\mathrm{p}) - 1\right) + 1\right]^{1/s}}\right]. \tag{32.27}$$

The pulse energy itself may be calculated from Equation 32.21 by taking the modulus square of both sides of the equation and integrating over the pulse. The result can be expressed as

$$\gamma^{-2} v_g \sigma_g \int_{-\infty}^{\infty} \left|\frac{\partial Y}{\partial t}\right|^2 dt + u_p = \kappa \ln \frac{\exp(G_-) - 1}{\exp(G_+) - 1}. \tag{32.28}$$

In general, the integral of the left-hand side cannot be calculated analytically. Two particular cases when this is possible have been analyzed in Vladimirov and Turaev (2005).

The first is the case of a model without spectral filtering when the integral can be set to zero. As noted by Vladimirov and Turaev (2005), this is a fairly crude approximation, as in fact the value of the integral does not disappear even in the limit of infinitely wide gain dispersion curve ($\gamma \to \infty$). Indeed, the integral is over the time of the pulse, and as such roughly proportional to the pulse duration. In the theories of ML, this duration scales as γ^{-1} meaning that $\left|\frac{\partial Y}{\partial t}\right|^2 \propto \gamma^2 Y^2$, so that the integral remains finite as $\gamma \to \infty$. In fact, as mentioned above, the theory with $\gamma \to \infty$ cannot predict the pulse shape or duration, leading to pulses collapsing to a delta-function shape. The total pulse *energy*, however, can be estimated *approximately* by neglecting the integral in the left-hand side of Equation 32.28 and thus obtaining an equation for u_p in the form

$$u_p = \kappa \ln \frac{\exp(G_-) - 1}{\exp(G_+) - 1}. \tag{32.29}$$

Equations 32.23, 32.24, and 32.26 through 32.29 form a closed system of five (nonlinear and transcendental) equations for the five unknowns: $G_\pm$, $Q_\pm$, and u_p. Vladimirov and Turaev (2005) identified this system as the *generalized New's model*, as it does not include spectral filtering (as the original New's model) but, unlike this model, does include arbitrarily large gain and absorption per pass, which are both essential features of diode lasers. The (numerical) solution gives the dependence of pulse energy (though neither duration nor peak power) on pulse parameters, represented by the unsaturated gain (which is related to pumping current) and absorption (which is related to the reverse bias applied to the absorber and the bandgap detuning between the gain and absorber sections). The other fundamental absorber parameter also dependent on the reverse bias, the absorber lifetime, only enters the calculations through the relaxation Equation 32.24 and does not influence the results from this model at all if $\tau_\alpha \ll T_{RT}$ (in which case, obviously, $Q_- \approx Q_0$).

The solution to this nonlinear algebraic equation system can then be substituted into the inequalities (32.13) to analyze the stability boundaries of the ML operating range with respect to the leading-edge and trailing-edge instability. The curves, in general, can only be calculated numerically; however, Vladimirov and Turaev (2005) noted that the leading-edge and trailing-edge instability boundaries met at the codimension-2 point lying on the linear threshold line (G_0-Q_0-ln$\kappa = 0$). This point can be calculated explicitly as

$$Q_0 = \ln \frac{\kappa(s-1)}{s\kappa - 1}; \; G_0 = \ln \frac{s-1}{s\kappa - 1}. \tag{32.30}$$

This means that the condition $s > 1$ for any range of successful ML to be present, derived in the traditional SCP approach for the case of small gain and loss per period, needs to be generalized in the case of arbitrary losses in the cavity as

$$s\kappa > 1. \tag{32.31}$$

In a more realistic construction, an extra geometric factor could also be required to take into account the fact that the absorber may be saturated by both the forward and reverse propagating wave simultaneously, which is not taken into account by a unidirectional ring laser model on which the approach above is based.

In the case of $G_0, Q_0, \ln\kappa \ll 1$, Equations 32.26 and 32.27 simplify to Equations 32.3 and 32.6, such that the equation for the pulse energy simplifies to $Q_- \frac{\exp(su_\mathrm{p})-1}{s} - G_- \left(\exp(u_\mathrm{p}) - 1\right) - u_\mathrm{p} \ln\kappa = 0$, which is the equation for u_p featured in the original New's theory of ML.

The second case when full (semi) analytical solution of the DDE model (with relaxation terms during the pulse neglected) is possible is when the dispersion is taken into account, but the saturation of gain and absorption during the pulse is assumed to be small, as in the Haus model of ML (though the gain and absorption themselves are not necessarily small, unlike the case of the traditional Haus model). Vladimirov and Turaev (2005) called this the generalized Haus model. In this case, a steady-state solution is sought in the form similar to Equation 32.12 in our notations, $Y(t + T_\mathrm{RT}) = e^{-i\delta\psi} Y(t - \delta T)$. Then, from Equation 32.21,

$$\gamma^{-1} \frac{\partial Y(t-\delta T)}{\partial t} + Y(t - \delta T) = F(u(t))Y(t), \tag{32.32}$$

where

$$F(u) = \sqrt{\kappa}\exp\left(G(u)(1 - i\alpha_\mathrm{Hg}) - Q(u)(1 - i\alpha_\mathrm{Hq}) - i\delta\psi\right) \tag{32.33}$$

is the "complex net gain," which can be written out explicitly, substituting the expressions (Equations 32.26 and 32.27) (with u instead of u_p) for $G(u)$ and $Q(u)$.

Next, assuming that the single-pass pulse shift is significantly smaller than the pulse duration and that the saturation of both the gain and absorption during the pulse is weak enough ($u(t) < u_\mathrm{p} << 1/s$)—the latter being the underlying assumption of Haus's theory—both sides of Equation 32.32 can be expanded in Taylor series up to the second-order terms in their respective arguments:

$$Y(t - \delta T) \approx Y(t) - \frac{\partial Y}{\partial t}\delta T + \frac{1}{2}\frac{\partial^2 Y}{\partial^2 t}\delta T^2,$$

and, generalizing the expansions (Equations 32.14 and 32.15) of the original Haus's theory:

$$F(u) \approx F_0 + F_o' u + \frac{1}{2}F_o'' u^2;\; F_0 = F|_{u=0};\; F_o' = \left.\frac{\partial F}{\partial u}\right|_{u=0};\; F_o'' = \left.\frac{\partial^2 F}{\partial u^2}\right|_{u=0}. \tag{32.34}$$

Then, the equation governing the pulse evolution is obtained in the form

$$\delta T\left(\frac{\delta T}{2} - \gamma^{-1}\right)\frac{\partial^2 Y}{\partial^2 t} - \left(\gamma^{-1} - \delta T\right)\frac{\partial Y}{\partial t} + \left(F_0 - 1 + F_o' u(t) + \frac{1}{2}F_o'' u^2(t)\right) Y = 0. \tag{32.35}$$

Recalling the definition of $u \propto \int |Y|^2 dt$, one identifies this second-order nonlinear differential equation as the generalization of the master equation of ML in Haus's theory, which admits solutions of the same form (Equation 32.16) as the original master equation. Six equations are then obtained for six real parameters: peak pulse power, duration, time shift δT, optical frequency shift $\Delta\omega$, phase shift per round-trip $\delta\psi$, and the chirp parameter β.

The stability limits in the generalized Haus's form can be obtained by substituting these solutions into the conditions (Equation 32.13). In general, they depend on the linewidth enhancement factors; however, for direct comparison with other models, the case of $\alpha_\mathrm{Hg} = \alpha_\mathrm{H\alpha} = 0$ is useful. Results of such analysis, reproduced from Vladimirov and Turaev (2005), are plotted in Figure 32.3. In the plot, the subscript N refers to results from New's model, generalized (solid lines) or standard (dashed lines); and the subscript

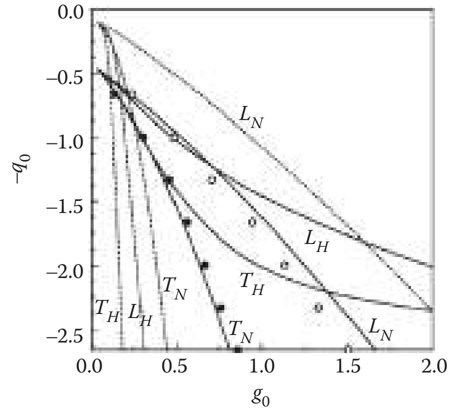

FIGURE 32.3 Stability boundaries of mode locking (ML) with respect to leading (L) and trailing (T) edge instabilities, calculated semianalytically in the DDE approach using traditional and generalized New's (N) and Haus's (H) models. In the calculations, $s = 25$, $T_{RT}/\tau_\alpha = 1.875$, $\tau_\alpha/\tau_g = 0.0133$, $\kappa = 0.1$; $g_0 = (\tau_\alpha/\tau_g)G_0$ as in text; q_0 corresponds to Q_0 in text. (From Vladimirov AG, Turaev D, *Phys Rev A*, 72, 033808, 2005. Reproduced with permission).

H to those from Haus's model (calculated with zero linewidth enhancement factors). The filled/empty dots are the leading/trailing instability boundary calculated by numerical integration of the model. In this numerical integration, the gain and absorber operators are treated on a continuous timescale, without the need to introduce separate timescales for pulse and the free relaxation period as in the iterative procedure. As seen in the figure, standard Haus's and New's models are extremely inaccurate in predicting the instability boundaries of ML in a typical diode laser (with the range predicted by New's model being too wide, and that from Haus's model, too narrow, as noted also in Dubbeldam et al., 1997). The generalized Haus's model gives good agreement within its validity limits at low currents/unsaturated gain values, while the generalized New's model gives very good agreement with numerical simulations at all parameter values (there are some modest deviations that are discussed in more detail below), the reason being that the spectral filtering term neglected in New's approach simply happens to be small in typical diode lasers. Thus, the large-signal nature of the DDE model is proven to be a very important advantage over the classical ML theories.

Apart from allowing some analytical progress in the limiting cases, the DDE model also allows the use of numerical techniques that have been developed for the analysis of DDEs, in particular of numerical packages that allow a full bifurcation analysis of DDEs. Such a study was indeed performed in Vladimirov and Turaev (2005), comprising the full (in)stability analysis of the stationary solution of the DDE. The stationary solution (the steady-state light-current characteristic of the laser) itself is found by seeking the steady-state light output in the form of $Y(t) = Y_{0s}\exp(i\Delta\omega_s t)$. Substituting this into the original Equations 32.21, 32.18, and 32.22 gives the steady-state amplitude and frequency in the parametric form

$$\begin{aligned} &\kappa \exp\left(G_s(Y_0) - Q_s(Y_0)\right) - \Delta\omega_s^2 = 0, \\ &\Delta\omega_s\gamma^{-1} + \tan\left[\Delta\omega_s T_{RT} + \left(\alpha_{Hg}G_s(Y_0) - \alpha_{H\alpha}Q_s(Y_0)\right)/2\right] = 0 \end{aligned} \quad . \tag{32.36}$$

Equation 32.36 is a transcendental trigonometrical equation and thus has an infinite set of formal solutions, corresponding to the cavity modes. The steady-state solution, as usual in the laser theory, is the one with the lowest value of the threshold gain $G_s(Y = 0)$, in other words, the closest to the peak of the gain spectrum. Figure 32.4, after Vladimirov and Turaev (2005), shows the results of a numerical bifurcation analysis of this solution. The line H_1 indicates the *Andronov–Hopf bifurcation* (transition from a steady state to a periodically oscillating solution with an amplitude smoothly increasing from zero as the controlling parameter,

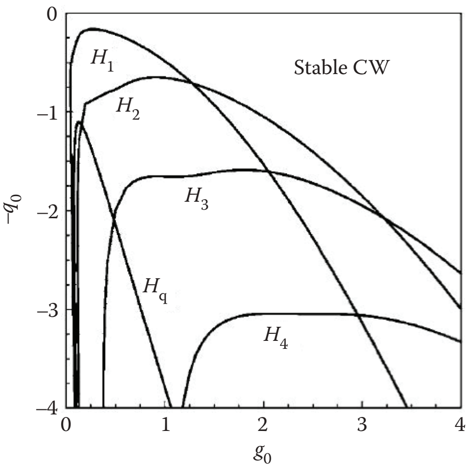

FIGURE 32.4 Bifurcation analysis of the steady-state solutions of the DDE model. Parameters used: $\gamma\tau_\alpha = 33.3$; $\alpha_{Hg,\alpha} = 0$, the rest as in Figure 32.3. The notations H_1, H_2, etc. refer to different harmonic numbers M_h; H_q is the boundary of the Q-switching instability. (From Vladimirov AG, Turaev D, *Phys Rev A*, 72, 033808, 2005. Reproduced with permission).

for example, the unsaturated gain in this case, increases beyond a critical value) corresponding to oscillations at the fundamental ML frequency. ML is predicted for a certain range of conditions regarding the values of the unsaturated gain and absorption, above threshold, whereas at high enough unsaturated gain (or current) and low enough absorption, continuous wave (CW) lasing is expected to be stable. The line H_q indicates the Andronov–Hopf bifurcation corresponding to *passive Q-switching* instability, also known as self-sustained pulsations, which essentially corresponds to the well-known relaxation oscillations in the laser. The positive feedback provided by the SA, which essentially favors pulsed operations, transforms the relaxation oscillations from damped to self-sustained pulsations. The frequency of these oscillations is determined mainly by the unsaturated gain, the gain cross section, the gain relaxation time, and the losses in the cavity, and is typically of the order of 1 GHz, or about an order of magnitude below the ML frequency. Thus, at low frequencies and with high enough amount of saturable absorption in the cavity, the ML pulse train is expected to be modulated by the self-pulsing envelope. The lines H_m, $m > 1$, show the bifurcations corresponding to a solution oscillating at the *m*th *harmonic* of the fundamental ML frequency. At high enough values of unsaturated absorption, there are ranges of G_0 (or current) in which ML at higher harmonics is predicted to be stable, but ML at fundamental harmonic is not.

These predictions are confirmed by a full numerical integration of the DDE model (Figure 32.5), showing the extrema of the laser intensity time dependence calculated for different values of the pumping parameter $g_0 = (\tau_\alpha/\tau_g)G_0$. For each unsaturated gain, the initial transient is omitted before the start of registering signals. At low values of g_0 (and thus current), the laser exhibits a regime when the ML pulse power is modulated by a passive Q-switching envelope, originally with nearly 100% modulation depth (Figure 32.6a). As the pumping parameter increases, the Q-switching modulation gradually decreases in amplitude and eventually the modulation regime undergoes the backward bifurcation, moving to a stable ML regime (this corresponds to the border of the trailing-edge instability in Figure 32.3). Within the area of stable ML, the fundamental round-trip frequency, a train of short pulses, is observed as in Figure 32.7a, whose amplitude increases with G_0. At higher still pumping, the laser dynamics see areas of harmonic ML at the second and third harmonic of the fundamental ML frequency (see Figure 32.7b and c), separated by narrow areas of unstable operation. Finally, the ML breaks up completely with the onset of chaotic modulation of the pulse power, with multiple pulse trains competing in the cavity, as in Figure 32.6b (the regimes separating fundamental frequency ML and harmonic ML areas are similar). Eventually, the system

undergoes a transition to CW single-frequency operation in agreement with the bifurcation diagrams of Figure 32.3.

An interesting result obtained in Vladimirov and Turaev (2005) is that, while the conditions (Equation 32.13) of negative net gain before and after the pulse are useful indications of the stability ranges of mode-locked operation, the onset of instabilities in numerical simulations does not coincide with those limits *exactly*. This may be caused in part by the omission of gain dispersion in the analytical study and in part by the neglect of absorber relaxation during the pulse. However, there is also a genuine physical reason for the discrepancy, in that not all small fluctuations in a ML laser were found to grow into full-scale instabilities even if a window of positive gain preceded the ML pulse. Instead, stable ML operation was shown to be possible for a range of parameter (unsaturated gain and absorption) values such that before the pulse,

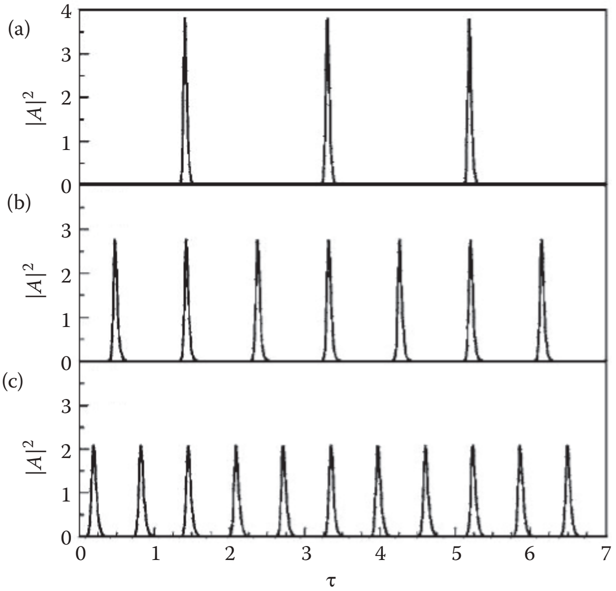

FIGURE 32.7 Illustration of the periodic regimes in Figure 32.5: fundamental frequency ML at $G_0 = 150$ (a) and first and second harmonic ML $G_0 = 225$ (b) and 270 (c). $|A^2| \propto |Y^2|$ is the normalized output intensity, $\tau = t/\tau_\alpha$ the normalized time. (From Vladimirov AG, Turaev D, *Phys Rev A*, 72, 033808, 2005. Reproduced with permission).

the fast absorption had recovered to its unsaturated value, but the slower gain continued recovery, leading to a window of positive net gain preceding the pulse (it may be worth noting that some previous studies, using modifications of Haus's model for semiconductor lasers, indicated the possibility of positive net gain at the *trailing* edge of a stable ML pulse as well; see, e.g., Vladimirov and Turaev, 2005). The possibility of stable ML operation despite a positive net gain window is confirmed by more accurate traveling-wave simulations. One of the consequences of this effect is that the onset of instabilities may be expected to be sensitive to perturbations such as spontaneous noise. The effect of spontaneous emission was indeed studied analytically and numerically in Vladimirov and Turaev (2005), with the noise introduced as a delta-correlated random term in the right-hand side of Equation 32.21. It was concluded that, while the onset of Q-switching oscillations (trailing pulse edge instability) is a dynamic process independent of noise, the onset of the chaotic envelope instability (leading edge instability) is strongly affected by the noise, with an increase in the noise narrowing the window of stable ML. This is fully confirmed by the more complex traveling-wave models (TWMs) described below.

The DDE model, when used as a numerical tool is, not only fully large-signal, but also self-starting: It does not require a trial pulse to start with and can reproduce the emergence of ML pulse train from randomly pulsing light output that is seen as the laser crosses the threshold condition. Thus, the model removes most of the shortcomings traditionally associated with lumped models of mode-locked lasers and presents a relatively simple yet very powerful tool for analyzing the qualitative tendencies of their behavior. As illustrated above, it combines analytical possibilities and numerical methods very naturally within the same framework and, as will be discussed in more detail later, predicts correctly virtually all the dynamic regimes and tendencies observed in a real laser.

An important advantage of the DDE model is that, although strictly speaking derived for the artificial unidirectional ring geometry, it captures enough of the main features of ML to be applicable, with some caution, to predict—at least qualitatively—the phenomena in mode-locked lasers of all types and designs.

An important example is the work presented in Marconi et al. (2014) where the DDE was used to analyze the behavior of mode-locked lasers with *long* delays (cavity round-trip times), comparable to, or even exceeding, the lifetime of carriers in the gain section ($T_{RT} >\sim \tau_g$, unlike the analysis in Vladimirov and Turaev (2005) where the typical situation was $\tau_\alpha < T_{RT} < \tau_g$). Marconi et al. (2014) used a bifurcation analysis similar to that discussed above and presented in Figure 32.3 to analyze the stability of various cavity configurations. The results are shown in Figure 32.8, similar to that presented in Marconi et al. (2014). It was found that the Andronov–Hopf bifurcation mathematically describing the onset of fundamental harmonic ML as discussed above, which is *supercritical* in the case of a short resonator so that ML exists only above its bifurcation point, becomes *subcritical* for a certain value of $T_{RT}/\tau_g > 1$. This means that the (fundamental) ML operation regime can exist below its bifurcation point, coexisting with the CW solution. At longer delays still, the area of stable ML extends below the CW threshold, meaning that ML can coexist with the off solution, thereby implying a bistability between them. Interestingly, during this folding phenomenon, the fundamental ML branch eventually disconnects from the CW solution, meaning that the ML appears for long delays through a saddle-node bifurcation of limit cycles instead of a nascent Andronov–Hopf bifurcation of the CW solution, making this scenario impossible to analyze by any weakly nonlinear analysis such as dynamic modal analysis (Section 32.3.2).

The change in dynamical scenario that occurs in Figure 32.8c has a profound consequence on the mode-locked solutions, as it can be seen in Figure 32.8c and d: The fundamental PML solution becomes stable even in the limit $T_{RT}/\tau_g \gg 1$. Moreover, a very large number of pulsing solutions with different number of pulses per round-trip and different arrangements become stable for the same parameter values. The authors reconstructed analytically some of these solutions, using the generalized New's approximation discussed above, for $T_{RT}/\tau_g = 1$ and restricting the analysis to equally spaced pulses solutions (harmonic PML), as presented in Figure 32.8d. Clearly, all these branches of solutions extend well below the laser threshold, where they stably coexist among them and with the off solution (although the authors noted that New's approximation of neglecting spectral filtering leads to an overestimation of the breadth of the ML region below threshold). This means that the harmonic mode-locked solution of maximal order that exists below threshold becomes fully decomposable, since essentially any pulse of this solution can be set on or off, which the authors confirmed by injecting a digitally modulated sequence of optical pulses into the cavity, which remained stable after a large number of round-trips, meaning that the laser worked as an active version of an optical buffer memory.

The model used in Marconi et al. (2014) was a DDE in its classical form of Vladimirov and Turaev (2005), derived for a hypothetical unidirectional ring laser with large gain and absorption per round-trip (and with the linewidth enhancement factors set to zero as the dynamic effects studied did not significantly depend on them), but the theoretical predictions of the paper were realized experimentally (Marconi et al., 2014)

using a *vertical external cavity surface-emitting* laser (VECSEL). A laser of this type consists of an amplifying (gain) chip and a semiconductor saturable absorber mirror (SESAM) chip, separated by an unguided free-space propagation path (with collimating optics to direct the beam and control the ratio of the spots over the two facets). Various harmonic regimes were realized with this laser, with the number of pulses between 0 and 19 successfully coexisting at high enough currents. The authors then went on (Marconi et al., 2015) to realize the multistability in the long laser to *generate individually addressable* pulses and sequences of pulses, all very well reproduced by the same DDE model.

This work is an important testament to the generality, power, and versatility of the DDE models: The experiments were stimulated by the theoretical predictions which in turn relied on the analytical capabilities (bifurcation analysis using analytical continuation techniques) unique, among semiconductor laser ML theories, to the DDE approach.

It can be pointed out that VECSELs, in fact, are the one class of mode-locked semiconductor lasers for which a delay-differential model, although of a somewhat different form to that used in Vladimirov and Turaev (2005), may be expected to give a fully *quantitative*, as well as qualitative, description of the behavior of a specific and realistic laser construction. As both the gain chip and SESAM are very short asymmetric resonators, with the gain section "length" much shorter than the spatial pulse duration, the lumped-element formalism is a very natural one for their description. The fact that no integration over length is needed for calculating G and Q allows the use of generic nonlinear $g(N)$ and $\alpha(N)$ dependences with no loss of accuracy, as well as introduction of fast gain and absorption saturation omitted in the original DDE of Vladimirov and Turaev (2005). A model based on an approach of this type was successfully used to analyze the dynamics of external-cavity VECSELs in a simple linear cavity (with the laser and SA chips facing each other and the output being from a partially reflecting mirror located between them). The predicted dynamic regimes, pulse durations, and stability ranges matched the ones previously reported in experimental papers, not only qualitatively, but with a reasonable numerical agreement (Mulet and Balle, 2005).

The mathematical distinction of the DDE model usable for quantitative and rigorous description of realistic VECSELs, such as the one used in Mulet and Balle (2005), from the one reported in Vladimirov and Turaev (2005) is, first, that gain and absorption operators, as well as the rate equations for the carriers, need to be modified to take into account the resonator nature of the amplifier and absorber sections and the short length of their active parts. Second, given the Fabry–Pérot rather than ring nature of the resonator, rather than having a single DDE for the light amplitude with the delay time equal to the cavity round-trip, the model for VECSELs in a linear geometry needs separate equations for the dynamics of light amplitudes in the gain and absorber chips, each of them containing a delayed term with a delay equal to *half* of the cavity round-trip.

With further delayed terms introduced, a model of this type can describe different VECSEL geometries, including a folded (rather than linear) cavity one and a colliding pulse operating VECSEL (Avrutin and Panajotov, in preparation).

More advanced constructions known as MIXCELs (standing for mode-locked integrated external cavity surface emitting laser) with the quantum well (QW) gain and QD absorber layers located in one chip, could be described by a similar, possibly even somewhat simpler, model, with the single chip reflectance operator containing the effects of both the gain and the absorption; the model for such a design would therefore be even closer to that of Vladimirov and Turaev (2005).

In the case of *edge-emitting* lasers, the application of a DDE model to a specific, realistic design is somewhat more tenuous. First of all, the DDE model as studied in Vladimirov and Turaev (2005) does not account for fast gain and saturable absorption nonlinearities due to interband processes. Although it could be possible to include them in the QD case, at least in some approximation, the explicit introduction of fast nonlinearities is not necessarily the best strategy. Instead, separate rate equations for dot and reservoir populations can be used. Second, Equations 32.18 and 32.22 for the gain G and absorption Q integrated over the length of the amplifier/absorber element are only accurate if both the gain and absorption have a simple linear dependence on the carrier densities in the corresponding elements, which is in itself an approximation (or if $G, Q \ll 1$). Third, the geometry of the system analyzed in a DDE model in the form presented in Vladimirov and Turaev (2005) is, as in most lumped models, somewhat artificial in that Equations 32.2 and 32.5 are, strictly speaking, valid only in a hypothetical unidirectional ring cavity. In a real laser, the pulse passes through both the amplifier and absorber twice, not once, with the reflected pulse traveling through areas in which gain or absorption has been already partially saturated by the incident pulse, and possibly partially recovered.

An attempt at taking into account a realistic edge-emitting tandem laser geometry in a large-signal *lumped* iterative (not DDE) model, with an end reflector by introducing averaging of gain/absorption over the corresponding sections, with reflections at facets taken into account, was made in a relatively early paper by Khalfin et al. (1995); the model gave good qualitative predictions of the laser performance; however, such an approach has its own inaccuracies as discussed in Avrutin et al. (2000), since it implicitly assumes pulse duration greater than the round-trip time, which by definition is not the case in mode-locked lasers and the results of Khalfin et al. (1995) were never compared to predictions of more accurate models to ascertain their accuracy.

More recently, a study specifically investigating modeling a Fabry–Pérot edge-emitting laser using a DDE model, importantly with a detailed comparison to the more rigorous and accurate model of a travelling wave type (see the next section), has been presented (Rossetti et al., 2011b). The simulations were performed for the special case of QD mode-locked lasers; however, the results appear to be quite generic. Rossetti et al. (2011b) improved the accuracy of the DDE approach by separating the laser into a number F_s of longitudinal sections (e.g., $F_s = 28$ sections were used in the calculations presented in the paper), some of which belong to the gain region and others to the SA, which results in what the authors termed a multisection DDE approach. Essentially, in the notations used here (the formalism of Rossetti et al., 2011b was somewhat more complicated because of account for two-level transitions peculiar to QDs), in a multisection DDE model, Equation 32.21 is rewritten with the single product $\sqrt{\kappa}\hat{G}\hat{Q}$ substituted by a concatenation of gains and losses in individual segments:

$$Y(t) = -\gamma^{-1}\frac{\partial Y(t)}{\partial t} + \left(\prod_{k=1}^{F_s}\sqrt{\kappa_k}\hat{G}_k\right)Y(t - T_{RT}). \tag{32.37}$$

Here, the loss $\sqrt{\kappa_k}$ includes both the distributed losses inside the segment and any lumped scattering/outcoupling loss between the segments k and $k+1$. The complex gain operator $\hat{G}_k$ for each section is calculated in the way similar to Equation 32.2 if the section is within the gain region and similar to Equation 32.5 if it belongs to an SA, with the length used being the length of the section. The gain (or loss) in each segment is calculated from a local rate equation for population inversion. The use of a number of segments gives the model some longitudinal resolution and allows for a more accurate modeling of the outcoupling losses; although not explicitly done in the model of Rossetti et al. (2011b), it can also include fast gain and absorption saturation in addition to the slow processes described by rate equations. The model, however, still contains a single delay term helping maintain the calculation efficiency that is one of the main advantages of the DDE approach. To account for bidirectional propagation, the Fabry–Pérot resonator had to be represented, somewhat artificially, by an equivalent ring resonator twice the length of the Fabry–Pérot one, with the SA length also doubled, and the distributed losses allocated carefully to represent the loss in the realistic cavity. With these approximations, the laser performance simulated by the multisection DDE approach was in good (though not perfect, e.g., the pulse amplitude was accurate to typically within about 10%) agreement with the traveling wave one as regards the pulse shapes, amplitudes, durations, and stability of the results with respect to a chaotic envelope instability. As in most QD mode-locked lasers, the design simulated did not show Q-switching instability, owing to the large damping of the relaxation oscillations, so it is not certain whether the multisection DDE model would accurately predict its limits in a laser in which Q-switching could occur. It can be said that the multisection DDE approach has some similarity to the decimated traveling wave one considered below, though unlike it still retains the unidirectional ring cavity assumption.

The DDE model also has been used recently to investigate the performance of a number of laser cavity designs and operating regimes more complex than purely PML in a simple tandem cavity, whether monolithic or VECSEL type.

In Arkhipov et al. (2013), the DDE model was used to analyze the performance of *hybridly*, rather than passively, mode-locked lasers. As in the experiments with which the calculations were compared, and as in previous simulations using a TWM (Avrutin et al., 1996), the hybrid ML was implemented by voltage modulation at an approximately resonant frequency applied to the SA. Within the DDE approach, this requires the modification of Equation 32.18 in the form

$$\frac{\mathrm{d}Q(t)}{\mathrm{d}t} = -\frac{Q_0 - Q}{\tau_\alpha}\left(1 + a_{\mathrm{mod}}(1 + \mathrm{F}_{\mathrm{mod}}(t)\right) - \left(1 - \exp\left(-Q\right)\right)\frac{P(t)}{U_\alpha}. \tag{32.38}$$

Here, a_{mod} is the amplitude of absorption modulation, $\mathrm{F}_{\mathrm{mod}}(t)$ is a periodic function of time, and $\mathrm{F}_{\mathrm{mod}}$ is a periodic function of time defined so as to vary within the limits $-1 < F_{\mathrm{mod}}(t) < 1$. The authors investigated various modulation profiles, the most straightforward of which was sinusoidal modulation $\mathrm{F}_{\mathrm{mod}}(t) = \cos(2\pi f_{\mathrm{mod}} t)$. The modulation frequency could be near resonance with the fundamental ML frequency, with $f_{\mathrm{mod}} = f_{\mathrm{P}} + \Delta f_{\mathrm{mod}}, \Delta f_{\mathrm{mod}} \ll 1/T_{\mathrm{rt}}$, with $f_{\mathrm{P}} \approx 0.9723/T_{\mathrm{rt}}$ being the free-running PML frequency, or at its second harmonic $f_{\mathrm{mod}} = 2f_{\mathrm{P}} + \Delta f_{\mathrm{mod}}$, or second subharmonic $f_{\mathrm{mod}} = f_{\mathrm{P}}/2 + \Delta f_{\mathrm{mod}}$.

Note that Equation 32.38 captures an important feature of voltage modulation of an SA: Both the unsaturated absorber and the relaxation time are modulated simultaneously.

The efficient DDE model allowed, first and foremost, for very effective numerical search for the *locking range* of hybrid ML (the range of frequency detunings $\delta f = \Delta f_{\mathrm{mod}} T_{\mathrm{rt}}$ within which stable hybrid ML was observed for a given modulation amplitude). This was done by long-time (3000 periods, with the last 200 periods stored) direct numerical simulation of the system (Equations 32.18, 32.21, and 32.22). For improved accuracy, the authors used dual characterization of the locking range, using, first, a straightforward bifurcation diagram with the field maxima and minima plotted, and, second, a stroboscopic diagram where, for each considered δf_{mod}, field intensities separated from each other in time by the interval $1/f_{\mathrm{mod}}$ were collected. Once locking was achieved and the period of the field intensity time trace became equal to $1/f_{\mathrm{mod}}$, all stroboscopic map points had the same value; otherwise, multiple values of the stroboscopic map at a given δf were observed. Figure 32.9 (reproduced from Arkhipov et al., 2013 with permission) illustrates both procedures, as illustrated in Figure 32.9a and b, as well as the calculated *locking tongue* (locking range borders in the coordinates δf, a_{mod}), shown in Figure 32.9c. The latter was in very good qualitative agreement with the observed values. The figure shows the fundamental harmonic locking range (the second harmonic one was very similar as could be expected); however, the simulations also predicted, for the first time and in agreement with the experiments published in the same paper, that a narrower range of *subharmonic* locking was also present due to internal nonlinearities in the laser.

In addition to numerical analysis, the DDE allowed an *analytical* asymptotic model for the calculation of the locking range to be developed, which was in very good qualitative agreement with the numerical simulations up to the modulation amplitude of $a_{\mathrm{mod}} \sim 0.5$–$0.6$. Most importantly, it was shown, in agreement with numerical results, that the magnitude of the locking range was *directly proportional* to the modulation amplitude, a fact also seen in other numerical simulations but only proven analytically in Arkhipov et al. (2013). Explicit, if rather complex, expressions for the proportionality coefficient between the locking range and a_{mod} were derived using perturbative analysis of the periodic ML solution.

Finally, Arkhipov et al. (2013) addressed the issue of the asymmetry of the locking range (it is easier to speed the laser up than to slow down), long known for hybrid ML and shown by both experiments and previous simulations; the authors attributed it to the variation of the absorber relaxation time and hence the average absorption value with modulation.

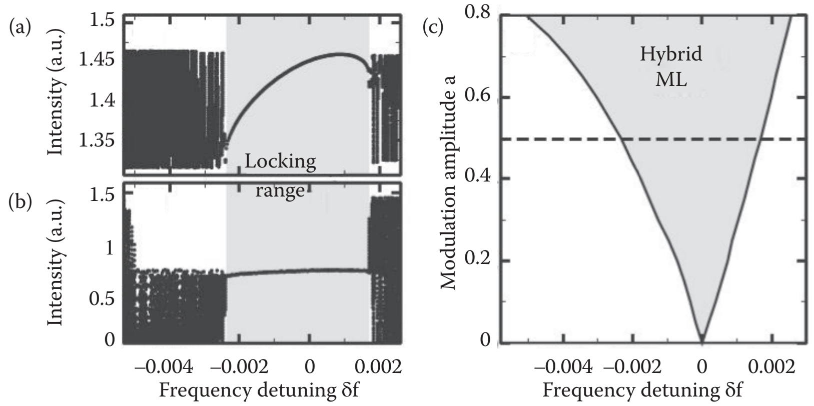

FIGURE 32.9 Numerical DDE estimate of the locking range of a hybrid ML laser. (a) Local maxima of the intensity time trace and (b) 1/fm periodic stroboscopic map points of emitted field intensity time trace at fixed modulation amplitude $a = 0.5$. In the locking range (gray), all ML pulses have the same peak intensity. (c) Locking tongue in the plane of two parameters: frequency detuning δf and modulation amplitude a. (From Arkhipov A. et al., *IEEE J Sel Top Quantum Electron*, 19, 1100208, 2013. Reproduced with permission).

The DDE was also used for modeling the dynamics of mode-locked lasers under the more special conditions of optical injection with a single (Rebrova et al., 2011) or, most recently, dual (Arkhipov et al., 2016c) optical lines, as well as under the condition of external optical feedback (Jaurigue et al., 2015, 2016; Otto et al., 2012). In all of these conditions, the versatility of the DDE allowed analytical insight into operating conditions, as well as direct numerical simulations.

Interestingly, the somewhat abstract nature of the DDE model led to the fact that two very different forms of the model could be used successfully to analyze the situations that in the experiment can be quite similar. In Jaurigue et al. (2015) and Otto et al. (2012), a model with multiple delays (as in the generalized Lang-Kobayashi model of a single-frequency laser with optical feedback from a strong external reflector) was used to analyze ML under external optical feedback, whereas in Arkhipov et al. (2015b), harmonic ML in a compound cavity consisting of an active laser subcavity and a passive one formed by an external reflector (which is very similar to optical feedback) was investigated by modeling both cavities as unidirectional ring ones as in the traditional form of the DDE; mathematically, the compound cavity was represented by two coupled DDEs. Both models showed, and were used to estimate the ranges of, fully or partially rendered harmonic regimes given an integer rational relation between the cavity lengths, and stressed the importance of the subwavelength variations in the cavity length (represented by phase shifts of light amplitude). All of these had been previously independently investigated for Fabry–Pérot laser geometries using frequency-domain and/or traveling wave time-domain models (see the next section), e.g., in Avrutin and Russell (2009). However, the advantage of the DDE model was, first, the possibility of efficient and instructive analysis of the bifurcation diagrams of the laser and, second, the generality as the results apply not just to Fabry–Pérot resonators but to other designs such as ring lasers.

A special version of the DDE model was developed (Viktorov et al., 2006) for analyzing *QD* mode-locked lasers. Detailed description of the properties of QDs as an active medium is beyond the scope of this chapter; the reader is referred to a specialized monograph (Rafailov et al., 2011) or the relevant chapters in the current handbook. In brief, there are two major (interrelated) features that distinguish the QDs from other semiconductor active media, particularly in the context of ML. The first of these is the complex carrier kinetics which in the case of the gain media involves the relatively slow (~5–10 ps) capture of carriers (electrons and holes) into the QDs and subsequent interlevel relaxation, and in the SA sections, the relatively complex nature of carrier escape involving intermediate levels (Viktorov et al., 2009). The second specific feature of QDs as an active medium is the noticeably nonequilibrium distribution of carriers between dots of different sizes and compositions (which therefore have different energy levels resulting in the inhomogeneous broadening of the laser line), and the possibility of dual-wavelength lasing due to the existence of (at least) two electron levels in each dots, the ground and excited state.

The original DDE model of QD mode-locked lasers (Viktorov et al., 2006) ignored inhomogeneous broadening and the excited-level transitions, and thus captured the first of these characteristic features but not the second. The equation for light field in the model was thus essentially the same as in the standard DDE but the equations for gain and absorber dynamics were changed more significantly to reflect the specific features of QDs. Still, even in this simplified form, the model allowed an explanation for a number of features of QD mode-locked lasers, such, first, as the suppressed Q-switching instability (Viktorov et al., 2006) due to the slow carrier capture in the gain section and, second, the enhanced ML at high temperatures due to faster SA relaxation (Cataluna et al., 2006, 2007). Later, more advanced versions of DDE for QD ML lasers have been developed with inhomogeneous broadening and lasing from different levels taken into account, e.g., Cataluna et al. (2010) and also Rossetti et al. (2011b) already mentioned above.

To summarize, DDE models are a very powerful tool capable of predicting, qualitatively describing, and giving unique analytical insight into all the main features and many of the peculiarities of ML in a semiconductor laser. With some caution, models of this type can be used for quantitative description of the performance of a specific laser design, but the reliability and accuracy of such a procedure may be limited in the case of realistic, multisection edge-emitting laser designs, particularly as they often comprise, in addition to the gain and absorber section, elements such as Bragg mirrors, phase-tuning sections, etc.

For these purposes, TWMs are preferable; they will be considered in the next section.

32.3.4 TWMs: The General Considerations

The most accurate and realistic, though usually the most computationally intensive, approach to simulating edge-emitting mode-locked lasers is offered by *distributed time-domain*, or *TWMs* (shown schematically in Figure 32.2c), which treat the propagation of an optical pulse through a waveguide medium with spatial as well as temporal resolution. The model then starts with decomposing the optical field in the laser cavity into components propagating forward (subscript "+") and backward (subscript "–") in the longitudinal direction (say, z):

$$Y(r,t) = \Phi(x,y)\left(Y_+ \exp(i\beta_{ref}z) + Y_- \exp(-i\beta_{ref}z)\right)\exp(-i\omega_{ref}t), \tag{32.39}$$

with Φ being the transverse/lateral waveguide mode profile and ω_{ref} and

$$\beta_{\mathrm{ref}} = n(\omega_{\mathrm{ref}})k_{\mathrm{ref}} = n(\omega_{\mathrm{ref}})\omega_{\mathrm{ref}}/c$$

being the reference optical frequency and the corresponding wave vector, respectively. This results in a reduced equation for slowly varying amplitudes $Y_\pm$, which has the form

$$\pm\frac{\partial Y_\pm}{\partial z} + \frac{1}{v_{\mathrm{g}}}\frac{\partial Y_\pm}{\partial t} = \left(\frac{1}{2}(\widehat{g}_{\mathrm{mod}} - \alpha_{int}) + ik_{\mathrm{ref}}\widehat{\Delta\eta}_{\mathrm{mod}}\right)Y_\pm + iK_{\pm,\mp}Y_\mp + F_{\mathrm{spont}}(z,t). \tag{32.40}$$

The equation is directly solved numerically without the partially analytical integration involved in deriving (Equations 32.2 and 32.5).

The gain and saturable absorption coefficients are most often parametrized as functions of the carrier density and, through the gain and absorption compression coefficients ε_{g} and ε_α, on the photon densities, which is most efficiently implemented using simple relations:

$$g = \frac{g_{\mathrm{lin}}(N)}{1+\varepsilon_{\mathrm{g}}S}; \quad \alpha = \frac{\alpha_{\mathrm{lin}}(N)}{1+\varepsilon_{\alpha}S}, \tag{32.41}$$

where $S = |Y_+|^2 + |Y_-|^2$. Note that taking the total intensity in the denominator of Equation 32.41 for both left- and right-traveling waves, although often used, may be an oversimplification for some problems as it assumes identical cross- and self-saturation coefficients between left- and right-traveling waves. A more accurate analysis may be important, in particular, in ring lasers (see Chapter 31 for more details).

The carrier density dependences of the linear gain and absorption $g_{\mathrm{lin}}(N)$ and $\alpha_{\mathrm{lin}}(N)$ are, in the simplest version of the model, taken in the standard linear $g_{\mathrm{lin}}(N) = \sigma_{\mathrm{g}}(N - N_{\mathrm{tr}})$ or logarithmic $g_{\mathrm{lin}}(N) = \sigma_{\mathrm{g}}N_{\mathrm{tr}} \ln \frac{N+N_1}{N_{\mathrm{tr}}+N_1}$ forms typical for semiconductor laser modeling in general (Coldren et al., 2012) (N_{tr} being the transparency carrier density and σ_{g}characterizing the gain cross section near transparency as shown in Sections 3.1 and 3.2; for the absorption, the linear approximation $\alpha_{\mathrm{lin}}(N) = \alpha_0 - \sigma_{\alpha}N$, also as shown in Sections 32.1 and 32.2, is most often used). In more accurate implementations (e.g., Javaloyes and Balle, 2010b), absorption $g_{\mathrm{lin}}(N)$ and $\alpha_{\mathrm{lin}}(N)$ are calculated microscopically with varying degrees of rigor; some of these implementations will be discussed in more detail in Section 32.5. The compression factors $\varepsilon_{\mathrm{g},\alpha}$ also may be either introduced phenomenologically or calculated microscopically for the two main types of optical nonlinearities in bulk and QW lasers: spectral hole burning and dynamic carrier heating. As pulse duration decreases and particularly for multi-GHz ML, the finite (subpicosecond) relaxation times $\tau_{\mathrm{nl}}^{(\mathrm{g,a})}$ of the nonlinearities become important. To take those into account, Equation (32.41) can be substituted by phenomenological relaxation equations: $\frac{\mathrm{d}\alpha}{\mathrm{d}t} = \frac{1}{\tau_{\mathrm{nl}}^{(a)}}\left(\frac{\alpha_{\mathrm{lin}}}{1+\varepsilon_{\alpha}S} - \alpha\right)$; $\frac{\mathrm{d}g}{\mathrm{d}t} = \frac{1}{\tau_{\mathrm{nl}}^{(\mathrm{g})}}\left(\frac{g_{\mathrm{lin}}}{1+\varepsilon_{\mathrm{g}}S} - g\right)$ (Martins et al., 1995). Some authors choose not to introduce $\varepsilon_{\mathrm{g},\alpha}$ due to carrier heating at all, instead including microscopic analysis of carrier temperature dynamics (Bischoff et al., 1997) and gain-carrier temperature dependence into the model. In QD lasers, with their strong spectral hole-burning effects (nonequilibrium carrier distribution in energy, with the energy levels resonant with the photon energy preferentially depleted), and relatively slow intradot relaxation, kinetic processes are often treated explicitly without introducing $\varepsilon_{\mathrm{g},\alpha}$ (see Section 32.5.1).

The dynamic correction $\Delta\beta = \Delta\eta_{\mathrm{mod}}k_{\mathrm{ref}}$ to the propagation constant, in bulk and QW lasers, is often approximated as related to the gain variation by means of a single parameter, the Henry's linewidth enhancement factor α_{H} (with different values used for the gain and absorber sections), e.g., using a relation $\Delta\beta = \Delta\beta_{\mathrm{SPM}} = -\alpha_{\mathrm{H}}(g - g_{\mathrm{th}})$, the latter parameter being the threshold (or any other reference) value of peak gain. This phenomenological approach, although the simplest and the most traditional, ignores the fact that the spectral dependence of gain and carrier-induced refractive index correction can be different, so the linewidth enhancement factor should be, generally speaking, spectrally and carrier density dependent.

The gain dispersion represented by the operator nature of gain $\hat{g}_{\mathrm{mod}}$ (and to a certain extent GVD, represented by the operator nature of the modal refractive index $\widehat{\Delta\eta}_{\mathrm{mod}}$) is very important in determining the *stability range* of ML (unless there is a dispersive element in the laser construction such as a DBR). As mentioned before, in the lumped model, no stable ML with a finite pulsewidth can be simulated in the absence of dispersion. In the distributed model, most models not including gain dispersion cannot predict stable ML either. Some authors (Bischoff et al., 1997) reported stable ML with finite pulsewidths simulated without the dispersion term, but the model of Bischoff et al. (1997) included finite relaxation times of nonlinearities, which may have had a side effect of introducing *effective* dispersion. As regards the numerical implementation of dispersion, in mode-locked laser constructions realized so far, the spectrum of mode-locked lasers, although quite broad, is still usually significantly narrower than that of gain/absorption, meaning that only the top of the gain curve needs to be represented accurately. Therefore, in most studies reported so far, the dispersion has been approximated in frequency domain, i.e., as function of $\Delta\omega = \omega - \omega_{\mathrm{ref}}$, as a simple, Lorentzian curve in complex numbers (similar to Equation 32.10 with $D = 0$), or Equation 32.20, equivalent to approximating the spectral properties of the material by those of an equivalent two-level medium with homogeneous broadening:

$$P^{\mathrm{T}}_{\pm}(\Delta\omega) = -i\hat{g} \cdot Y^{\mathrm{T}}_{\pm}(\Delta\omega) = -i\frac{g(N,S)}{1 - i\left(\Delta\omega - \Delta\omega_{\mathrm{p}}(N)\right)/\gamma(N)} Y^{\mathrm{T}}_{\pm}(\Delta\omega), \tag{32.42}$$

where the superscript T means Fourier transformed variable in frequency domain; $\gamma(N)$ is the gain spectral width parameter as in Equations 32.10 and 32.20; $\Delta\omega_{\mathrm{p}}(N)$ is the spectral shift of the gain peak from the reference frequency, and $g(N, S)$ can be implemented as in Equation 32.41 (for the absorption, the same method can be used). In time domain, this can be implemented numerically by two alternative but largely equivalent methods. The first one, used in a number of papers (e.g., Bandelow et al., 2001), and traceable to early work on pulse generation in lasers with active media with homogeneously broadened gain spectrum (Fleck, 1968), consists of introducing a separate differential equation for gain polarization, as in the DDE approach. With the gain spectrum centered at the reference frequency ($\Delta\Omega'' = 0$), it takes a particularly simple form, similar to that of Equation 32.21 in the DDE approach:

$$\frac{\partial P_{\pm}(z,t)}{\partial t} = -\gamma\left(P_{\mathrm{f,b}}(z,t) - i\frac{g}{2}(N,S)Y_{\mathrm{f,b}}(z,t)\right). \tag{32.43}$$

The second method of introducing gain dispersion involves using digital filters of varying complexity (Avrutin et al., 2000, 2005; Heck et al., 2006). In the case of a simple Lorentzian gain, the filter is straightforwardly represented as an infinite impulse response (IIR) one of the form of

$$P_{\pm} = -i\hat{g}Y_{\pm} = -i\frac{\gamma}{2}\int_{o}^{\infty} g(z,t-\tau)Y_{\pm}(z,t-\tau)\exp\left(-\tilde{\gamma}_{\mathrm{p}}\tau\right)\mathrm{d}\tau;\ \tilde{\gamma}_{\mathrm{p}} = \gamma - i\Delta\omega_{\mathrm{p}}. \tag{32.44}$$

In practice, the integral requires only storing one iteration in the computer memory: For small integration steps Δt it is easily implemented using a slight generalization of the formula given originally in Schell et al. (1991) as

$$P_{\pm}(t) = \exp\left(-\tilde{\gamma}_{\mathrm{p}}\Delta t\right)P_{\pm}(t-\Delta t) - i\left(\gamma/\tilde{\gamma}_{\mathrm{p}}\right)\left(1 - \exp\left(-\tilde{\gamma}_{\mathrm{p}}\Delta t\right)\right)\frac{g(t)}{2}Y_{\pm}(t).$$

This method of gain dispersion implementation is more tolerant to the simulation time step than the separate differential equation (Equation 32.43), but may be not very accurate if the steps are not small enough (Avrutin et al., 2005; Schell et al., 1991). A more complex, but also somewhat more robust, form of a digital filter implementation of dispersion was described in Carroll et al. (1998) and applied to ML (see, e.g., Jones et al., 1995).

In a recent paper (Javaloyes and Balle, 2010b), a more complex digital filter, representing a more accurate model of the spectra of the complex dielectric permittivity (gain/absorption and refractive index), derived from a microscopic approach and allowing for the realistic fundamental absorption edge spectrum to be modeled, has been implemented; this will be discussed in Section 32.5.

The dispersive nature of the correction $\widehat{\Delta\beta} = k_{\mathrm{ref}}\widehat{\Delta\eta}_{\mathrm{mod}}$ to the (real part of) the propagation constant is usually less important than gain dispersion. In cases when very short (subpicosecond) pulses may be expected in the simulation, the operator $\hat{\Delta\beta}$ may include an additional term describing GVD of the structure (Avrutin et al., 1996)

$$\hat{\Delta}\beta Y = k_{\mathrm{ref}}\widehat{\Delta\eta}_{\mathrm{mod}}Y = \hat{\Delta}\beta_{\mathrm{SPM}}Y - \frac{\beta_2}{2}\frac{\partial^2 Y}{\partial^2 t^2}, \tag{32.45}$$

where the first term describes the self-phase modulation effects, and the second, the GVD, with $\beta_2 = \frac{1}{c}\frac{\mathrm{d}n_{\mathrm{g}}}{\mathrm{d}\omega}$ the first-order GVD coefficient, n_{g} being the group velocity refractive index of the laser waveguide. Numerical simulations (Avrutin et al., 1996) show that GVD affects the parameters of picosecond pulses significantly for the dispersion values of $\mathrm{d}n_{\mathrm{g}}/\mathrm{d}\omega \sim 10^{-14}$ s. Thus, this term is usually negligible in most QW lasers (where the GVD magnitude is estimated as $\mathrm{d}n_{\mathrm{g}}/\mathrm{d}\omega = 10^{-16}$–$10^{-15}$ s) and indeed is omitted in most models of mode-locked laser diodes published to date. In the microscopic or semimicroscopic implementations of TWM (Section 32.5), the dynamic and spectral variation of real, as well as imaginary, part of the dielectric permittivity of the material, and thus the active layer contribution to GVD, is implemented self-consistently. The dispersion (material and waveguide) of the passive waveguide structure is neglected but is believed to be weaker.

The terms containing the forward-back and back-forward propagating coupling constants $K_{\pm,\mp}$ need be included in the model only if a *Bragg grating* is present at the position z (and time t); the constants $K_{\pm}$ and $K_{\mp} = K_{\pm}^{*}$ are, in general, complex due to both refractive index and gain/absorption grating being possible. In the context of a mode-locked laser, accounting for a grating may be needed either if the laser construction contains a DBR section, or to account for *standing wave-induced gratings, or short-scale spatial hole burning* that is important if pulses propagating in opposite directions collide in the active medium (coherent colliding pulse effect). The standing wave-induced grating exists due to the carrier population being increased in the antinodes of the standing wave. Within the SA, where ML pulses are typically engineered to collide, this decreases the local absorption (Martins et al., 1995) and forms an absorption (and possibly refractive index, due to self-phase modulation) grating, to which the fast nonlinearities responding to the standing wave also contribute. The magnitude of the periodic carrier density modulation is then given by the equation (Martins et al., 1995)

$$\frac{\mathrm{d}}{\mathrm{d}t}N_{\mathrm{grat}}(z,t) = -\frac{N_{\mathrm{grat}}(z,t)}{\tau_{\mathrm{grat}}} + \frac{v_{\mathrm{g}}}{2}\left(Y_{+}^{*}\hat{\alpha}Y_{-} + Y_{-}^{*}\hat{\alpha}Y_{+}\right), \tag{32.46}$$

where $\hat{\alpha} = -\hat{g}$ is the saturable absorption operator; the grating relaxation time in QW materials is mainly determined by ambipolar diffusion with the coefficient D_a:

$$\frac{1}{\tau_{\mathrm{grat}}} = \frac{1}{\tau_{\alpha}} + \frac{16\pi^2 D_{\mathrm{a}} n_{\mathrm{g}}^2}{\lambda^2}, \tag{32.47}$$

where λ is the lasing wavelength in vacuum. An estimate gives a value of ~1 ps for the ambipolar diffusion coefficient of 2×10^{-4} m^2/s typical for III–V materials. From the magnitude of carrier density modulation, the coupling in QWs can be estimated as $K_{\mathrm{fb}} \approx i\frac{\partial\alpha}{\partial N}N_{\mathrm{grat}}(z,t)(1 - i\alpha_{\mathrm{H}\alpha})$. Assuming the Henry factor of the absorber is small, as was done in Martins et al. (1995), the grating becomes a purely absorption grating, smoothed down by diffusion. Equation 32.46 is written in terms of SA rather than gain section parameter since in ML lasers designed to utilize the colliding pulse effects, pulses traveling in different directions collide in the SA rather than the gain sections (the former, as will be discussed in the following section, assists ML, the latter impedes it). However, a TWM should contain the grating population in all type of sections; in gain sections, the gain operator $\hat{g} = -\hat{\alpha}$ is used.

The final term in Equation 32.40 is the random noise source that leads to the self-starting of the model and is essential for modeling of noise and pulse jitter. At the laser facets, standard reflection/transmission boundary conditions are imposed on $Y_{\pm}$; thus, unlike the delay-differential model, the traveling wave one accounts accurately for the laser geometry.

The traveling-wave equations are coupled with coordinate-dependent rate equations for the relevant populations. In the context of QW and bulk lasers:

$$\frac{\mathrm{d}}{\mathrm{d}t}N(z,t) = \frac{J(z,t)}{ed_{\mathrm{a}}} - N\left(BN + \frac{1}{\tau_{\mathrm{nr}}} + CN^2\right) - v_{\mathrm{g}}Re\left(Y_{+}^{*}\hat{g}Y_{+} + Y_{=}^{*}\hat{g}Y_{-}\right), \tag{32.48}$$

with J/ed as the pumping term, J being the current density, e the elementary charge, d_{a} the active layer thickness, τ_{nr} the nonradiative recombination rate, and B and C are usually identified as the bimolecular recombination constant and the Auger recombination rate, respectively. Carrier capture dynamics is sometimes taken into account by adding an extra equation for carrier densities in the contact layers, but its significance for most mode-locked lasers (with the exception of QD active media and possibly some specially engineered QW constructions) tends to be modest, except where direct current modulation is involved.

TWMs are very powerful and general and their use is not restricted to ML edge-emitting lasers (see Chapter 31).

The main limitations of TW models are, first, the absence of any analytically solvable cases—the approach is by its very essence numerical, though some analytical insight is given by the modal decomposition of the traveling wave solution (see Chapter 31). Second, there is the fact that, in their traditional form, TWMs pose considerably higher requirements on the computing time and memory compared to delay-differential models. This is mainly due to the fact that, in the traditional implementation of the TWMs, time and space steps are usually related as $\Delta z = v_{\mathrm{g}}\Delta t$, meaning that the computational timescales as $1/\Delta t^2$ and need to be sufficiently short (a typical spatial step being 1–5 μm) to reproduce the pulse characteristics faithfully (the problem is mathematically stiff). However, with the development of computer resources, this limitation has become progressively less important; and the numerical technique of *decimation* has allowed efficient decoupling of time and space steps (see Section 32.5.2). Several commercial or free software simulators of laser diodes include traveling-wave approach of some form as the core of their solver; some of those are directly applicable and have indeed been applied for the analysis of ML lasers; see, e.g., Avrutin and Rafailov (2012), Section 32.5.2 Avrutin and Rafailov (2012), and Chapter 31.

32.4 The Main Predictions of Mode-Locked Laser Theory

In this section, we shall overview some of the main results of ML modeling that can be obtained on a mainly phenomenological level.

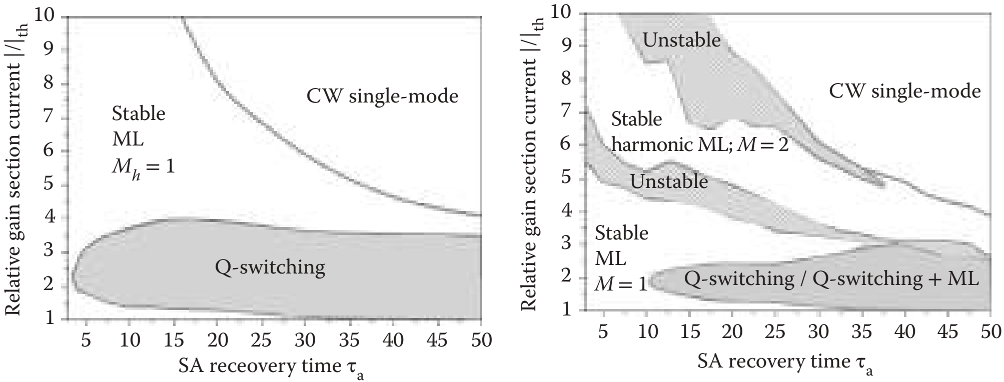
32.4.1 Operating Regime Depending on the Operating Point

The most basic result of all the modern ML theories, confirmed by the experiments, is that the dynamics of semiconductor lasers intended for ML can be quite rich and can show, apart from stable ML near the fundamental round-trip frequency, a number of other dynamic regimes. Here, we shall briefly discuss the general trends in their dependence on the laser parameters.

One of the most important features in the dynamic map of operating regimes of a mode-locked laser is the self-sustained pulsations, or passive Q-switching instability at low currents. As shown in Figure 32.5, produced by the DDE model, the range of currents, or unsaturated gain, values in which this regime is observed increases with the amount of saturable absorption in the laser (which, in a given laser construction, either QW or QD, may be varied to some extent with reverse bias, due to electroabsorption). The other model parameter affected by the reverse bias is the *absorber lifetime* τ_{α}, which is known to decrease approximately exponentially with the reverse bias in QW materials (see Nikolaev and Avrutin, 2003 and references therein) and to some extent in QDs too (Malins et al., 2006). The dependence of the Q-switching range on τ_α is not straightforward; the *Q*-switching range tends to be broadest at a certain absorber recovery time, of the order of the round-trip time though somewhat longer, as can be seen for example in Figure 32.10. At longer τ_α values, the SP range slightly decreases. However, it also decreases as τ_α is *decreased*, and when τ_α reaches a certain value, of the order of a fraction of the round-trip, the Q-switching instability disappears completely, leaving a broad area of stable ML. This is illustrated in Figure 32.10, which is produced using a TWM and shows approximate borders of different dynamic regimes for a representative laser with a short, relatively broadband (length 50 μm, coupling coefficient $\kappa = 120\ \text{cm}^{-1}$) DBR section similar to that realized in Bandelow et al. (2006) and with a cavity length designed for the fundamental ML frequency either near 80 GHz (Figure 32.10a) or near 40 GHz as in the experimental study (Figure 32.10b).

The importance of both τ_α and the unsaturated absorption in determining ML properties means, first, that care needs to be taken when interpreting the bias voltage effects on the performance of either QW or QD mode-locked laser, as the unsaturated absorption, the saturable absorption cross section, and the SA recovery time τ_α are all likely to be affected. The effect on the latter is probably the most significant though, as the dependence of τ_α on voltage is quite strong (exponential), while the effect on the unsaturated absorption appears, from measured threshold currents, to be more modest. Second, it means that for the same absorber parameters, longer lasers with longer repetition periods are less likely to suffer from the Q-switching instability, which needs to be kept in mind when analyzing the dynamics of QD lasers (due to the relatively low gain, these often have to be quite long if stable operation at the ground level wavelength band is desired).

The lower current (or unsaturated gain) limit of the self-pulsing instability may be positioned either below or above the low boundary of ML itself, depending on the gain and absorber saturation energies (*s*-parameter) and the absorber recovery time. If the boundary for ML is below that for self-pulsing (which tends to happen in longer lasers, when τ_α is significantly smaller than T_{RT} but not small enough to completely eliminate self-pulsing), then the stable ML range is split in two by the self-pulsing area, with an area of stable ML seen below the Q-switching limit at currents just above the threshold. The area is narrow, however, and the pulse powers generated in this regime are typically rather low. If, on the other hand, the boundary for ML is above that for self-pulsing (which tends to be the case for shorter lasers or longer absorber relaxation time, when $T_{RT} > \tau_\alpha$), then an area of pure self-pulsing, with noisy/chaotic filling of pulses, is seen at small to modest excess currents above threshold, as in Figure 32.5; as the current is increased, the pulses acquire a regular structure and the combined ML/SP regime develops.



(a)

(b)

FIGURE 32.10 Schematic diagram of regimes in a generic QW mode-locked laser operating at the repetition rate of 80 GHz (a) and 40 GHz (b), calculated using a phenomenological TWM.

Comparing Figure 32.10a and b, we notice that the dynamics of the laser become richer with the increase of the cavity round-trip time, or, equivalently, of the number of modes in the laser spectrum. Indeed, the dynamic behavior of the short-cavity laser in Figure 32.10a displays only regular deterministic regimes (Q-switching, ML, CW) and only the fundamental frequency ML ($M_\mathrm{h} = 1$ in Equation 32.1). In contrast, the dynamics of the longer laser in Figure 32.10b contain a range of currents corresponding to stable *harmonic* ML with $M_\mathrm{h} = 2$, as in the DDE model. It is separated from fundamental frequency ML by a band of currents in which the laser shows the second (after Q-switching) main type of instability of ML: the leading edge, or chaotic, instability. As was shown by the DDE model, the onset/lower border of this instability is pushed somewhat toward higher currents by the increased amount of absorption in the laser. In addition, as illustrated in Figure 32.10b, shortening absorber relaxation time also somewhat decreases the risk of this instability.

At high currents, the unstable operating regime gradually evolves into some type of (irregular) quasi-CW operation (few modes present), which for some parameter values, with higher currents still, gives way to single-frequency, stable CW operation, as shown in Figure 32.10 (for longer τ_α) and predicted also by DDE. Whether or not this true single-frequency CW operation is achieved at a practically feasible current depends on the length of the laser and the gain bandwidth; longer lasers (with a repetition frequency ~10 GHz and below) with broader gain spectrum tend to not reach true CW under any realistic pumping current, instead operating in a chaotic quasi-CW regime with a narrow spectrum including only a few modes.

In shorter lasers, as in Figure 32.10, a direct transition from stable ML, fundamental (Figure 32.10a) or harmonic (Figure 32.10b), to CW operation is also possible. This takes the form of a Hopf bifurcation, with the ML pulses acquiring a constant background with increased current and then their amplitude gradually reducing to zero resulting in CW operation.

32.4.2 The Main Parameters That Affect Mode-Locked Laser Behavior

In addition to determining the operating *regime* of the laser as discussed in the previous section, the theoretical models allow also the effects of the operating point on the main parameters of the optical pulse to be analyzed. Here, we shall concentrate mainly on the PML regime, in which case the most important parameters whose effect on the laser behavior the modeling can allow us to investigate are as follows:

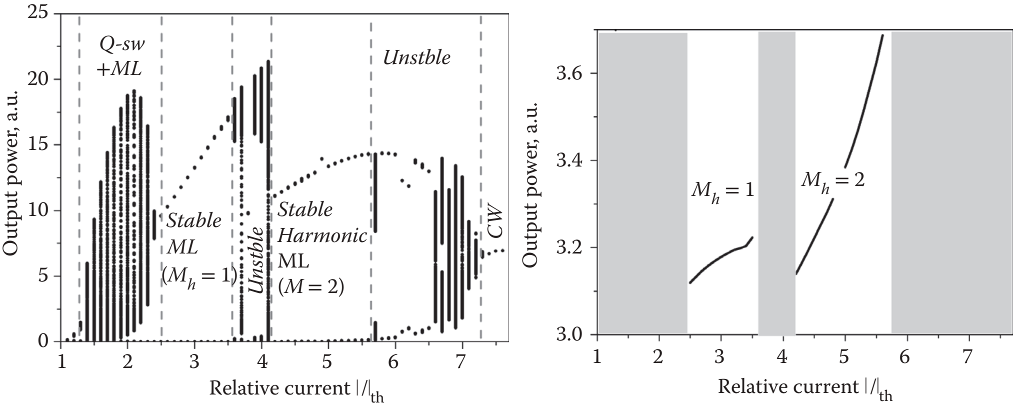
32.4.2.1 The Pumping Current

The pulse *amplitude* grows with pumping current, as illustrated in Figure 32.11, calculated by a traveling-wave simulation of the laser of Figure 32.10b. Notice that qualitatively the behavior of the pulse amplitude shown in Figure 32.11a is quite close to the bifurcation behavior seen from Figure 32.5, except that in the TWM, and with the inevitably different set of parameters, only the second rather than third harmonic operation is predicted (it was also noted by some authors (Vladimirov et al., 2009) that the dynamics of an ML laser in the TWM can predict stable or unstable trailing pulses at different time detuning from the prevalent pulse stream, whereas the DDE simulation gives only harmonic operation even in unstable regimes).

As regards the pulse *duration* shown in Figure 32.11b, it has been predicted by early frequency-domain theories (Lau and Paslaski, 1991) to reach a minimum near the area of Q-switching instability; this has been later confirmed by both experiments and time-domain simulations and can be also seen in Figure 32.11b. The pulse duration thus tends to grow with current within the stable ML range *above* the upper boundary of Q-switching. On the other hand, if an area of stable ML below the Q-switching range is observed (which, as discussed above, is sometimes the case in longer resonators), then a *decrease* of pulse duration with current can be expected within this area.

32.4.2.2 The Absorber Relaxation Time

The dependence of the pulse duration on τ_α (and this on the absorber bias) within the stability range is shown in Figure 32.12. As seen in the figure, to achieve stable ML, the absorber relaxation time needs to be



(a) (b)

FIGURE 32.11 (a) Simulated dependence of the pulse amplitude on the pumping current (bifurcation diagram) for the laser of Figure 32.10b for one value of absorber recovery time, calculated with a phenomenological TWM. (b) Calculated pulse duration for the same laser within the current ranges for stable ML.

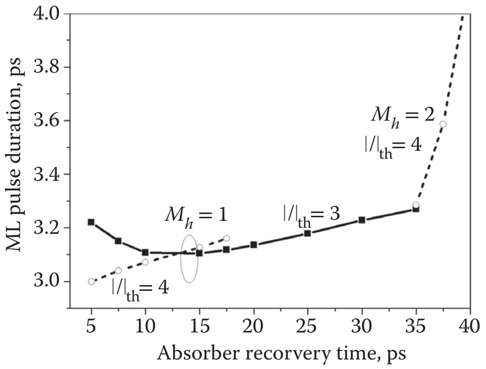


FIGURE 32.12 Typical simulated dependence of pulse duration on the absorber recovery time for two current values: simulations using a phenomenological TMW. Laser design same as in Figure 32.10b.

within a certain range. Values of τ_α above a certain value produce instabilities of either leading or trailing edge type, and may mean switching to harmonic ML. Within the stable ML range, a decrease in τ_α tends to shorten the pulses, due to both the effects of partial absorber relaxation during the pulse and, probably more significantly, to the fact that the slow relaxation of the absorber leads to the absorber being always partially saturated, thus reducing the initial absorption Q_-. This trend can sometimes be reversed for *very* short τ_α, of the order of a few picoseconds, when the absorber may not be saturated efficiently; therefore, there may be an optimum τ_α for shortest pulse generation, though for some laser parameter values this optimum τ_α may be so small as to be technologically unattainable.

The requirement of small τ_α in ML has been recognized from the early days. The methods of reducing τ_α in experiments included, first, ion implantation in early work (Deryagin et al., 1994; Zarrabi et al., 1991), second, choosing QW materials for faster sweepout, e.g., AlGaInAs rather than InGaAsP quaternaries (Green et al., 2011; Hou et al., 2010a,b, 2013) or even QD materials in which SA dynamics is known to be fast (Erneux et al., 2009; Rafailov et al., 2011; Viktorov et al., 2009), third, engineering the QW profile to include steps or oblique rather than vertical walls (Nikolaev and Avrutin, 2004), and fourth, using unitraveling carrier absorbers (Scollo et al., 2005, 2009); see Avrutin and Rafailov (2012) for more detail.

32.4.2.3 The s-Factor, or the Absorber to Gain Saturation Energy Ratio

While it is well known that the increase in s (determined by Equation 32.17) facilitates ML, it is not immediately intuitively clear whether an increased s helps ML stability, as it is known (Kuznetsov, 1985) that the passive Q-switching regime, which is one of the instabilities affecting ML, is also facilitated by an increase in s. However, the results from both DDE and traveling-wave simulations (Bandelow et al., 2006) show that in fact it is the stable ML range that is increased with s at the expense of the Q-switching (or self-pulsing) range.

In VECSELs, the most straightforward way of increasing the s parameter is manipulating the spot ratio of the gain module and the SESAM. For instance, the fast absorption saturation, or the high ratio s, was crucial in achieving the bistability between the off-state and the ML state necessary for low-repetition rate ML and addressable pulse generation studied in Marconi et al. (2014, 2015); this was achieved by placing the SESAM in the Fourier plane of the focusing lens so that the spot area $A_{X\alpha}$ was determined only by the diffraction limit. In *monolithic* diode lasers, a similar strategy can be pursued to some degree by *tapering* the laser waveguide so that the absorber region is narrower than the gain region. Used originally for Q-switching QW lasers in a “bow-tie” construction with the narrow SA in the middle of the cavity and the two amplifier sections tapering outward (Williams et al., 1994), this strategy has later been realized most convincingly in QD mode-locked lasers (Nikitichev et al., 2011a,b; Thompson et al., 2006, 2009); see Avrutin and Rafailov (2012) for an overview of results achieved. More often, monolithic structures use the same waveguide structure in the gain and absorber sections for ease of fabrication and fiber coupling, and so $A_{X\alpha} = A_{Xg}$. The parameter s is then equal to the *absorber-to-gain cross section ratio* $s = \sigma_a/\sigma_g$. QWs, with their sublinear (approximately logarithmic) dependence of gain on carrier density (population inversion) have long been seen as superior to bulk material for ML performance, since the sublinear $g(N)$ helps achieve $\sigma_a/\sigma_g > 1$. Vladimirov et al. (2004) and Vladimirov and Turaev (2005) used their DDE analysis to conclude further that when designing a QW laser for ML purposes, a structure with a *smaller number* of QWs was preferable to one with a larger number—indeed, the smaller number of QWs means a smaller confinement factor, hence a higher threshold carrier density and therefore a smaller dg/dN at threshold due to the sublinear $g(N)$, which in turns gives a higher value of the ratio s. These considerations influenced the choice of structures with just two to three QWs for realizing DBR ML lasers capable of generating very stable pulses about 2-ps long at 40 Gb/s (Bandelow et al., 2006). It may be argued that the same logic also, in part, accounts for the success of QD mode-locked lasers, in which the dependence of gain on the (total) carrier density in the active layer is even more sublinear than in QWs; however, it has to be borne in mind that the concept of total carrier density is somewhat misleading in QDs; a more accurate picture is given by more complex analysis, considering separately the population of the dots themselves and of the reservoir that supplies them with carriers.

32.4.2.4 Gain and Group Velocity Dispersion Parameters

Most models of mode-locked laser operation predict that without *gain* dispersion, stable ML with a finite pulse duration is impossible, and so the gain dispersion, or width of gain curve, represented by the parameter γ in the DDE or ω_L in the TWM, should play an important role in determining the pulsewidth and stability. Within the range of gain dispersion typical in mode-locked semiconductor lasers, which usually corresponds to $\hbar\omega_L$ of the order of tens of meV (or the wavelength range of tens of nm) and does not change too much with operating conditions or construction, gain dispersion is not the most drastic factor limiting the pulsewidth. However, achieving a broad gain spectrum is still desirable. This may be one of the advantages of QD active media, as discussed below.

GVD, like gain dispersion, acts to broaden the pulses in the case of normal dispersion, which is the usual situation in semiconductor lasers. As discussed above, the effect of this parameter is modest in most semiconductor lasers since the pulse durations at which it would become important (~100 fs) are never achieved; however, with stronger GVD possible in QD lasers, some account for this effect may be necessary.

32.4.2.5 The Gain and Absorber Compression Coefficients

Pulses generated by ML lasers tend to be of picosecond duration. This is below the critical pulsewidth at which the fast gain saturation, rather than the average carrier density dynamics, begins to dominate the pulse amplification and shaping, at least in the gain section; this critical pulse duration has been estimated (Mecozzi and Mork, 1997; Mork and Mecozzi, 1997) to be of the order of $\frac{\varepsilon_g}{v_g \frac{dg}{dN}}$. With typical semiconductor parameters, this estimate gives values of the order of 10 ps. Thus, the gain compression (and, similarly, absorber compression) effects and the coefficients that describe them (if introduced) may be expected to play a significant part in ML properties.

In practice, the effect of nonlinearities is twofold. First, gain compression tends to broaden ML pulses, with absorption compression having the opposite effect. Second, and in some regards more important, an increase in gain compression *stabilizes ML operation*, suppressing the *Q*-switching instability (the latter can be easily shown by rate equation analysis of Q-switched lasers (Avrutin et al., 1991). Again, fast absorber saturation has the opposite effect.

32.4.2.6 The Self-Phase Modulation in the Gain and Absorber Sections

Within the simplest phenomenological approach, the linewidth enhancement factors have a relatively modest effect on pulse *energy* for a given current and absorption, but a more noticeable one on amplitude and duration. They do not significantly affect the onset of the *Q*-switching instability (the lower current or unsaturated gain limit of ML stability), but have a stronger effect on the upper limit of ML stability associated with the irregular envelope and pulse competition. Mode-locked behavior is the most stable when the gain and absorber linewidth enhancement factors are not too different from each other. According to the DDE model predictions, the most stable operating point (which also corresponds to the highest pulse amplitude and lowest duration) is for $\alpha_{Hg} = \alpha_{H\alpha}$. Traveling-wave and modal analysis predicts that the best-quality ML is achieved with $\alpha_{Hg} > \alpha_{H\alpha}$, see, e.g., Salvatore et al. (1996); the discrepancy is likely to be caused by the different geometry of the long amplifier and the shorter absorber. The main parameter determined by the linewidth enhancement factors is the *chirp* (dynamic shift of the instantaneous frequency) of the pulse. Passively mode-locked pulses tend to be up-chirped (with the instantaneous optical frequency increasing toward the end of the pulse) when the absorber saturation factor $\alpha_{H\alpha}$ is small and the chirp is mainly caused by α_{Hg}. With a certain combination of α_{Hg} and $\alpha_{H\alpha}$ (typically $\alpha_{Hg} > \alpha_{H\alpha}$), an almost complete compensation of chirp is possible; with $\alpha_{H\alpha} > \alpha_{Hg}$, the pulse is typically down-chirped (Salvatore et al., 1996). As up-chirp is observed more frequently than down-chirp in experiments, one may conclude that typical values of $\alpha_{H\alpha}$ are smaller than α_{Hg}. In active ML, *down-chirp* is typically observed, while hybrid ML allows the chirp to be tuned to some extent, and there is typically a combination of bias and current or voltage modulation amplitude for which the chirp is minimized and close to zero, if only in a very narrow range of operating parameters. In a more detailed semimicroscopic model discussed in Section 32.5, the linewidth enhancement factor is not introduced *explicitly*, with gain and refractive index correction being implemented as imaginary and real part of the same complex dielectric permittivity, respectively, but the tendencies would appear to be general enough to merit being taken into account.

32.4.2.7 The Laser Geometry and Saturable Absorber Location

All the results discussed above could be obtained using either DDE or TWMs, though the latter usually give slightly more realistic predictions (e.g., both types of models predict harmonic operation at high currents, but in the case of multi-GHz PML ($T_{rt} \ll \tau_g$), operation at harmonics above the second one, predicted by the DDE model, is usually not observed experimentally; TWMs tend to predict only fundamental and second harmonic operation, which agrees with the experiment (Bandelow et al., 2006). The effects of a realistic laser cavity geometry (Fabry–Pérot versus ring cavity, absorber position and length, facet reflectances, etc.) on the ML characteristics are one area where the TWMs have an obvious advantage. They are, for example, highly suitable for analyzing the effects of specialized *harmonic* ML designs for high-frequency generation. These fall into two categories.

The first is colliding pulse mode-locking (CPM), including *multiple (MCPM)* (Martins et al., 1995; McDougall et al., 1997) and *asymmetric (ACPM)* (Shimizu et al., 1995, 1997) colliding-pulse ML constructions. These achieve ML at the M_h-th harmonic by positioning one SA (in CPM or ACPM) or several SAs (in MCPM) at fraction(s) M'_h/M_h of the laser cavity length, where $M'_\text{h} < M_\text{h}$ is an integer, and M' (or at least some of the values of M'_h in case of MCPM) and M are mutually prime. The standard CPM corresponds to $M_\text{h} = 2$ (and obviously $M'_\text{h} = 1$) with the SA in the center of the cavity. Constructions of this type have produced ML operation at rates of up to 860 GHz (Shimizu et al., 1997) (in that particular case, $\lambda = 1.55$ μm ACPM construction used $M'_\text{h} = 5, M_\text{h} = 12$). A more detailed review is given in Avrutin et al. (2000). The alternative harmonic ML technique is the use of a *spectrally selective laser cavity*. This may be in the form of a *compound cavity*, which has one or several *intracavity reflectors* (ICRs) positioned at fractions M'_h/M_h of the laser cavity length, rather like the SAs in the MCPM or ACPM technique. The highest ML repetition rates reported to date have been achieved by GaAs/AlGaAs ($\lambda \approx 0.89$ μm) lasers with the ICRs in the shape of deeply etched slots, either single or multiple in a 1-D photonic-bandgap (PBG) mirror arrangement (Yanson et al., 2002). A 608-μm long cavity used ICRs at 1/33 of the cavity lengths, giving $F = 2.1$ THz (similar structures with lower M_h values produced ML at bit rates of the order of hundreds of GHz depending on M_h and L).

TWMs have been long since been used for detailed analysis of the CPM (highlighting the importance of *incoherent* colliding pulse effect, the fact that the SA is saturated simultaneously by pulses propagating in both directions, as described by Equation 32.48, as opposed to coherent CPM effect, the self-induced grating described by Equation 32.46, which in semiconductors is less important than in other active media due to diffusion smoothing of the grating). All studies also predict higher stability and shorter pulses with CPM than with ordinary PML, in good agreement with experiment. A version of TWM was also used to explain and analyze the first realization of MCPM (Martins et al., 1995).

In terms of compound-cavity harmonic ML, TWM can help analyze the effects of the slot reflectances and positions (Yanson et al., 2002; Hou et al., 2010b, 2013) and bias current (Hou et al., 2013), with very good qualitative, and good quantitative, agreement with experiments. A TWM study was also used to propose and analyze the use of an alternative method of harmonic selectivity in a mode-locked laser resonator, a sampled grating reflector (Kim et al., 1999), later successfully realized experimentally, see, e.g., Hou et al. (2014) and references therein.

In principle, qualitative analysis can also be possible with DDE models (in fact, CPM can be analyzed, and ACPM predicted, in VECSEL structures using a DDE model (Avrutin and Panajotov, in preparation)), but this requires a customized model for each design whereas TWMs adapt to new design through a simple change of parameters. Harmonic ML is also one area where the time-frequency domain approaches (Section 32.3.2), despite their limitations, can give some insight into the cavity geometry required for successful harmonic operation (Martins et al., 1995; Yanson et al., 2002); however, TWM is still preferable for full quantitative description of the regime.

In addition to CPM, TWM modeling was also used to highlight another possibility allowing for a better saturation of the SA, which consists in placing the absorber close to antireflection-coated laser facet. This design is termed anticolliding mode-locking (ACML) and is inverse to that used for solid-state lasers where the absorber is usually placed close to a high reflection mirror, leading to self-colliding pulse mode-locking (SCML). In this latter situation, the pulse is allowed to interfere constructively with its own reflection onto the mirror leading to an improved absorber bleaching. For semiconductor laser diodes, however, such interferometric effects are rather weak due to the large value of the carrier diffusion coefficient which, in turn, reduces the coherent population grating created by the pulse self-interference as illustrated by Equation 32.47. The analysis of the ACML (Javaloyes and Balle, 2011) showed that this design leads to a substantial increase in output power, a reduction in amplitude and timing jitter, and an enlargement of the range of currents where stable PML can be obtained. The reason is a consequence of the strong increase of the laser field along the cavity axis and as it propagates toward the anti-reflection facet, yielding a more intense saturation of the absorber, and comparatively a weaker saturation of the gain. These regimes where the field is widely nonuniform along the cavity is one of the cases where a proper analysis demands using a TWM approach.

TWM was also used for analysis and optimization of the geometry of a number of other ML laser designs. Simulations of long-cavity ($F_{\text{rep}} \sim 10$ GHz) actively, passively, and hybridly mode-locked DBR lasers predicted that the optimal hybrid and PML performance could be achieved by placing the SA near the facet rather than at the DBR (Hasler et al., 2005), probably largely due to the more efficient absorber saturation as discussed above (Javaloyes and Balle, 2011). TWM studies were also used to predict, in agreement with experiment, that extended cavity laser designs containing a passive section were preferable to all-active ones in terms of pulse duration and chirp (Camacho et al., 1997).

32.5 Microscopic and Semimicroscopic Approaches in Mode-Locked Laser Modeling

32.5.1 The Basics of Microscopic Input in Mode-Locked Laser Simulations

As discussed above, phenomenological models of ML, either of delay-differential or traveling wave types, can be successfully used to predict a number of qualitative tendencies and, to a degree, qualitative parameters of the ML process. However, for detailed comparison with experiments, some microscopic input regarding the gain and SA section material is highly desirable. Some attempts at adding elements of microscopic analysis to models of the type described in the previous section has been undertaken for some time, see, e.g., Bischoff et al. (1997) for a relatively early example. The main challenge, and the main need for microscopic input, arguably, is the accurate modeling of interplay of the *spectral and temporal properties* of the material and laser dynamics. Most importantly, in most QW and, in some cases, QD lasers, the operating wavelength is at the sharp edge of the SA absorption spectrum. As the absorber is saturated, the absorption edge shifts, which lead to a change in the operating point, variation in the absorber saturation parameters affects self-phase modulation, etc. Likewise, due to the absorber selectivity, the operating point can be detuned from the gain peak in the amplifier section. In particular, this makes it difficult to construct a simulated map of regimes in the plane of "gain section bias current/absorber bias voltage," since the voltage affects simultaneously the absorber recovery time (relatively easy to model semimicroscopically as discussed below) and, more importantly, the spectral position of the absorption edge hence the unsaturated absorption and the cross section. This complex interplay of effects is difficult to capture with Equation 32.42 or any of its time-domain implementations, for the SA in particular, and to a degree for the gain section too. A more accurate (and thus ideally microscopically informed) model of gain and, particularly, saturable absorption spectrum as function of population (carrier density), and ideally temperature, is thus required.

The difficulty with this problem is that a realistic microscopic evaluation of gain/absorption in semiconductors is a formidable problem. To do so rigorously requires a many-body quantum mechanical approach (Chow and Koch, 1999), which is a task so complex from the point of view of the various physical effects at work, and so computationally resource-intensive that, at the time of writing, only a handful of research teams worldwide have both the expertise and the computer capacity to attempt it, and to our knowledge only one (the partnership between the Philipps-Universität Marburg and the University of Arizona) is performing this task routinely. The approach has been applied to some mode-locked laser problems, notably single-pass pulse modifications (Bottge et al., 2014) and steady-state ML pulse formation (Kilen et al., 2016) in ultrashort-pulse mode-locked VECSELs, and has informed some work on edge-emitting ML lasers, but to the best of our knowledge not yet been integrated into full analysis of high-bit-rate ML dynamics.

Even in the simpler single-particle approximation ignoring many-body effects, microscopic evaluation of the gain/absorption spectrum in a semiconductor material is, in general, rather nontrivial. For the case of a QW, or, with some reservations, QD active medium, the gain in the single-particle approach is calculated as

$$g(\hbar\omega) = A \sum_{\mu,\nu} \int \left| M^2_{\mu\nu} \right| (E_{\mathrm{e-h}}) \rho_{\mu\nu}(E_{\mathrm{e-h}}) \left(f_{\mathrm{e}}(E_{\mathrm{e}}^{(\mu)}) + f_h(E_{\mathrm{h}}^{(\nu)}) - 1 \right) L' \left(\hbar\omega - E_{\mathrm{e-h}} \right) \mathrm{d}E_{\mathrm{e-h}}. \tag{32.49}$$

Here, A is a proportionality coefficient, $E_{\mathrm{e-h}}$ is the electron–hole energy separation, $E_{\mathrm{e}}^{(\mu)}$ and $E_{\mathrm{h}}^{(\nu)}$ are the energies of the electron in the conduction subband (in the case of a QW material) or level (in the case of QD material) μ and the hole in the valence subband/level ν, which are fully defined by the subband/level numbers and energy separation. Furthermore, $M^2_{\mu\nu}$ and $\rho_{\mu\nu}$ are the squared matrix element of the transition and the reduced density of states, respectively (each of which, in general, varies with energy and is, in general, calculated from a transcendental equation in the case of nonparabolic QW subbands), f_{e} and f_{h} are the electron and hole distribution functions (which in the case of QW materials are very close to Fermi distributions given by the carrier density N and temperature T, and for QDs, in general, need to be calculated from separate kinetic equations), and L'' is the bell-shaped linewidth broadening function.

For a bulk semiconductor material (rarely used in mode-locked diode lasers), the summation over μ and ν is not necessary as there are no multiple subbands in the valence and conduction bands, and the reduced density of states and the matrix element are simple analytical functions of energy.

Still, the expression for the gain/absorption spectrum, in general, can only be evaluated numerically in all cases. The refractive index modulation, needed to consider self-phase modulation in mode-locked lasers, is then reconstructed using Kramers–Kronig relations.

The results are rather difficult to parametrize and to implement in a time-domain model. Simple linear or logarithmic approximations of the microscopic results, often used in the phenomenological models described in the previous section, capture the carrier density dependence of the gain peak and the saturated absorption, but not the spectrum.

The first step toward simplifying the problem is to approximate the linewidth broadening function L'' (which in the general case of a non-Markoffian phase relaxation characteristic of a highly populated semiconductor has quite a complex shape) by a simple Lorentzian form, which follows from a density matrix analysis with a Markoffian phase relaxation with a constant decay rate γ_T and is thus essentially identical to the function describing homogeneous broadening in a two-level system (Equation 32.42):

$$L'(\Delta\omega) = \mathrm{Re}L(\Delta\omega) = \frac{1}{\pi} \frac{\gamma_T}{\gamma_T^2 + \Delta\omega^2}; L(\Delta\omega) = \frac{1}{\pi} \frac{1}{\gamma_T - i\Delta\omega}. \tag{32.50}$$

This form of L' is advantageous because the dynamic correction to the refractive index or the real part of the dielectric permittivity (“imaginary gain”) is then calculated using the same equation as Equation 32.49 but using the complementary linewidth broadening function $L''(\Delta\omega) = ImL(\Delta\omega) = \frac{1}{\pi} \frac{\Delta\omega}{\gamma_T^2 + \Delta\omega^2}$, eliminating the need for Kramers–Kronig transformation and allowing both gain and refractive index variation to be implemented in time domain as discussed below.

Two main routes can then be successfully followed for using the results of Equation 32.49 in time-domain analysis required for ML simulations.

The first one consists in using a number of approximations in order to simplify the expression (Equation 32.49) (and its imaginary counterpart for the refractive index variation) to a level that permits the integration in energy to be performed analytically, and thus can be realistically parametrized as a (analytical) function of carrier density N and photon energy $\hbar\omega$. This has been achieved (Balle, 1998; Javaloyes and Balle, 2010a) by considering a QW material with a single, parabolic subband for both electrons and holes (hence constant reduced density of states), ignoring the energy dependence of M^2 (and γ_T) and considering (at least in the original version of the model) a very low (mathematically, zero) temperature. In the *frequency* domain (Balle, 1998), this results in a complex dielectric permittivity correction (with the refractive index correction as the real part and the gain as the imaginary part) in the form

$$\chi(\omega, N) = -\chi_0 \left[2\ln\left(1 - \frac{D}{u-i}\right) - \ln\left(1 - \frac{b}{u-i}\right)\right]. \tag{32.51}$$

Here, χ_0 is a constant proportional to the matrix element M^2 (Balle, 1998) (which in practice can be used as a fitting parameter in the model), $D = \frac{\pi d_{\mathrm{QW}}\hbar}{m\gamma_T}N$ is the reduced carrier density, d_{QW} and $m = \left(m_{\mathrm{e}}^{-1} + m_{\mathrm{h}}^{-1}\right)^{-1} \approx m_{\mathrm{e}}$ being the QW thickness and the reduced mass of the electron–hole pair; $b = \frac{\hbar k_m^2}{2m\gamma_T}$, k_m being the maximum wave vector in the first Brillouin zone of the semiconductor crystal; and the frequency of the optical transition is parameterized as $u = \frac{\hbar\omega - E_{\mathrm{g}}}{\hbar\gamma_T}$, where the bandgap E_{g} includes N- and T-dependent renormalization.

This result was used, among other applications, in the work in DDE modeling of mode-locked VECSELs (Mulet and Balle, 2005) discussed in Section 32.3.3. In such lasers, the operating frequency and the spectral selectivity of the laser cavity are mainly determined by the resonator properties of the gain chip. A full time-domain implementation of the gain spectrum was thus not required; instead, the complex dielectric permittivity was linearized around the spectral point of operation which, as mentioned in Section 32.3.3, was sufficient to achieve very good qualitative, and good quantitative, agreement with previously reported experiments.

In time domain, the general form of polarization has the same form as Equation 32.44

$$P_{\pm} = \int_0^{\infty} \chi(\tau)Y_{\pm}(t-\tau)\mathrm{d}\tau. \tag{32.52}$$

The time-domain version of Equation 32.51 results (Javaloyes and Balle, 2010a) in an integration kernel more complex than the simple exponential of Equation 32.44, specifically of the form

$$\chi_{\mathrm{g}}(\tau, N) = \chi_0 e^{-\left(\gamma_T + i\left(\omega_{\mathrm{g}} - \omega_{ref}\right)\right)\tau}\frac{2e^{-i\gamma_T D\tau} - 1 - e^{-i\gamma_T b\tau}}{\tau}. \tag{32.53}$$

Here, $\omega_{\mathrm{g}} = E_{\mathrm{g}}/\hbar$; the rest of parameters are the same as in Equation 32.51 and the normalized carrier density D is, strictly speaking, evaluated at the time $t - \tau$; however, since the carrier density even in the faster recovering SA, let alone the gain section, does not change noticeably on the timescale of $1/\gamma_{\mathrm{T}}$, using the value at time t is usually accurate enough (Javaloyes and Balle, 2010a). Despite being, strictly speaking, only applicable for very low temperatures such that $\kappa_{\mathrm{B}}T \ll \hbar\gamma_T$, the kernel (Equation 32.53) is a reasonable approximation for the highly degenerate gain medium. Its accuracy can be further improved to include the finite temperature, though this results in a more complex expression including special functions.

For the case of SAs, an alternative kernel expression was derived (Stolarz et al., 2011) with a finite temperature taken into account from the start, but with the Fermi distribution functions substituted by Boltzmann exponentials, which is usually a safe approximation for the weakly degenerate SA material; in this case,

$$\chi_{\alpha}(\tau, N) = \chi_0 e^{-\left(\gamma_T + i\left(\omega_{\mathrm{g}} - \omega_{\mathrm{ref}}\right)\right)\tau}\left\{D\left[\frac{a_c}{a_c + i\gamma_T\tau} + \frac{a_v}{a_v + i\gamma_T\tau}\right] - \frac{1 - e^{-i\gamma_T b\tau}}{i\gamma_T\tau}\right\}, \tag{32.54}$$

where $a_{c,v} = \frac{m}{m_{c,v}}\frac{\hbar\gamma_T}{\kappa_B T}$ and the rest of the parameters are as in Equation 32.53. Unlike the simple purely Lorentzian kernel of Equation 32.44, neither of the functions (Equations 32.53 and 32.54) allow for a simple iterative solution using only the previous point in time; instead, the integral must in practice go to an integration limit in τ of about $\tau_{\text{lim}} \sim (3\text{–}6)/\gamma_{\text{T}}$, making the number of previous points necessary for the integration $\tau_{\text{lim}}/\Delta t$.

Despite being managed/mitigated in part by the efficient numerical implementation (Javaloyes and Balle, 2010a), this approach is still quite taxing on the computer resources if implemented straightforwardly in a TWM, since the need for numerical integration in the dispersion operator adds to the general limitations of the TWM approach (the stiffness of the problem requiring a small time step, and computational timescaling as $1/\Delta t^2$ due to the $\Delta z = v_{\text{g}}\Delta t$ condition). Its efficiency can, however, be improved drastically with the *decimation* technique discussed in Section 32.5.2.

The semimicroscopical approach in this form was successfully used to model a number of mode-locked laser designs, including a "straightforward" two-section laser with an SA at a facet (Javaloyes and Balle, 2010b), a colliding-pulse mode-locked laser (Tandoi et al., 2013), and a specialist ring laser with an intracavity filter for spectral flattening and pulse duration reduction (Moskalenko et al., 2013); we shall consider the results of Tandoi et al. (2013) here in somewhat more detail as an illustration of the possibilities and certain limitations of the model.

While the quantitative agreement with experimental results is still not entirely accurate, microscopic models of this type have allowed a number of new possibilities compared to purely phenomenological approaches. The first of these is a much more meaningful, and directly comparable with experiments, prediction of the map of regimes in the "gain section current/absorber bias" plane. Indeed, in QW materials, the voltage applied to the SA has a double effect. First, it decreases the absorber recombination time. To a good accuracy, this is described with an exponential dependence, e.g., in Tandoi et al. (2013), an expression

$$\tau_{\text{SA}} \approx \tau_0 \exp[-F/(f F_0)] \tag{32.55}$$

was used, with $F_0 = (\kappa_{\text{B}} T)/(ed_{\text{QW}})$ being the activation field predicted by the simple thermionic excitation theory (Cavailles et al., 1992), and a correction factor f is introduced heuristically to take into account the interplay between tunneling and thermionic processes (and possibly any well profile distortion). The values $f = 0.5$ and $\tau_0 = 50$ ps were given by fitting the measured $\tau(V_0)$ but agreed well with estimates from more sophisticated theory (Nikolaev and Avrutin, 2003). Second, in materials where the quantum-confined Stark effect (QCSE, absorption shift with voltage) is significant, a voltage variation changes the bandgap, thus affecting the operating point of the laser (unsaturated absorption and saturation cross section), which the microscopic model successfully captures. This tends to be more pronounced in InGaAsP than in aluminum-containing quaternaries. Strictly speaking, QCSE affects also the shape of the absorption spectrum, but this is as yet to be included in the model, since to the best of our knowledge there is as yet no accurate calculation of absorption in a QW with both carriers and electric field present.

Finally, analysis of CW ML behavior requires, in addition to models of absorption spectrum and the recovery time, also a model of the current heating in the absorber. Indeed, the material bandgap that features in the kernels (Equations 32.53 and 32.54) is the renormalized temperature- (and carrier density-) dependent one, and the absorber can get significantly (up to about 10°) heated by the photocurrent flowing through it. This can be modeled (Tandoi et al., 2013) using a separate equation for the absorber bandgap:

$$\frac{\mathrm{d}E_{\text{g}}^{(\text{SA})}}{\mathrm{d}t} = -\gamma_{\text{therm}}\left(E_{\text{g}}^{(\text{SA})} - E_{\text{g0}}^{(\text{SA})} + 2\pi R_{\text{th}} j_{\text{SA}}\left(\left|V_{\text{SA}}\right| + V_{\text{bi}}\right)\right). \tag{32.56}$$

Here, R_{th} is the thermal resistance of the SA, the photocurrent density can be estimated as $j_{\text{SA}} = eN_{\text{SA}}d_{\text{QW}}/\tau_{\text{SA}}$, and the voltage seen by the active region in the SA is a sum of the built-in potential drop $V_{\text{bi}} = E_{\text{g0}}^{(\text{SA})}/e$ and the applied reverse bias $\left|V_{\text{SA}}\right|$. The parameters of the model were fitted in Tandoi et al. (2013) with the experimental measurements, and then the thermal relaxation rate γ_{therm}, which in reality is of the order of inverse microseconds, sped up to 10^8 s^{-1}, still slower than all characteristic times of laser dynamics but within the possibilities of the model.

Several features observed from the experimental results were well reproduced by the model, e.g., the optimal pulses around 600 fs long were found in the case of a SA occupying 4% of the cavity; some deviation from the best experimental results (430 fs) can be attributed to the approximate nature of the fitting of the gain curve with the two-band model (Equation 32.53).

With the microscopically informed gain and SA models as well as the voltage dependence on the SA recovery time, we constructed in Tandoi et al. (2013) maps of major characteristics of laser behavior in the "amplifier section current—absorber voltage" plane (Figure 32.13). The evolution of the ML quality as a function of the current followed the predictions of the DDE and TWM theories, with a minimal bias current to obtain the ML. The inspection of the time traces indicates that the degradation at high currents is due to the leading-edge instability and to the competition with other harmonics ML solutions, where three or four pulses propagate within the cavity. The evolution of the dynamical regimes as a function of the reverse bias was more subtle. In the AlGaAs materials studied in Tandoi et al. (2013), QCSE was weak and only the SA recovery time varied. This was, however, sufficient to capture the essential physical effects at work and to reproduce the output power decrease and the photocurrent density increase with V_{SA}. A faster SA has enough time to recover its full absorption between pulses and, therefore, presents the full amount of its unsaturated absorption to the pulse, which allows increased losses and photocurrent. Additionally, the photocurrent generated in the SA induces a detuning of the SA bandgap, which eventually hinders ML and decreases the output power. This is due to the fact that the SA can efficiently be modulated only within a limited spectral region around the bandgap and that the absorption increases on the blue side of the spectrum.

The alternative approach to including microscopically informed gain and absorption spectra into a mode-locked laser model has been so far implemented mainly in the context of QD lasers. In QD media, carriers are localized in individual dots and so the global carrier–carrier collisions that establish a common quasi Fermi level in a bulk or QW material are not present. QD lasers still show inhomogeneous

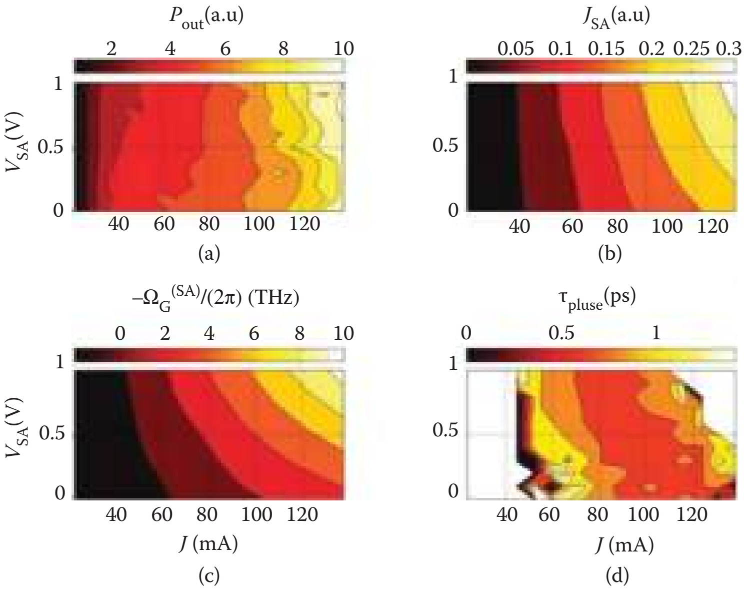

FIGURE 32.13 Parameter maps as a function of the SA reverse bias and of the gain section currently calculated using a TMW with decimation and analytical gain dispersion spectrum, for (a) output power P_{out}, (b) photocurrent density j_{SA} flowing out of the SA section, (c) bandgap of the SA section $-E_g^{(SA)}/h$, and (d) pulsewidth τ_{pulse}. The SA was 4% of the cavity length (optimal case, in agreement with measurements). (From Tandoi G. et al., *IEEE J Sel Top Quantum Electron*, 19, 1100608, 2013. Reproduced with permission).

broadening described mathematically by an equivalent of the reduced density of states in Equation 32.49, but the nature of this broadening is different from the case of bulk or QW materials and stems, not from a continuous energy spectrum of electrons and holes at each point in the material, but from the presence of a large number of dots, with fluctuating dot size and composition, and thus energy levels, in any microscopically large material sample, as already mentioned in Section 32.3.3. The Fermi energy distribution among the carriers occupying the multiple energy levels is established, not by the fast carrier–carrier collisions as in bulk and QW, but by slower processes of capture and escape and is thus only approximate at room temperatures and nonexistent at cryogenic temperatures. The gain thus cannot always be parameterized as a function of the total carrier density N. Instead, the populations of multiple individual levels need to be determined dynamically by solving rate equations including the kinetic processes of capture, interlevel relaxation, and escape, as well as spontaneous and stimulated recombination (see Rafailov et al., 2011 and the corresponding chapter in this handbook for a detailed description). In this case, trying to obtain an integral in Equation 32.49 analytically is problematic (some approximate methods have been discussed in Rafailov et al. (2011) for the room temperature case, but their accuracy has not been tested). Instead, a number of dynamic variables representing population of levels, or slices of the energy spectrum of the carriers in the material (different values of $E_{\text{e-h}}$ in Equation 32.49), at each point in time and space are introduced; the problem thus becomes not two, but (at least) three-dimensional: time, space, and transition energy. To reproduce a spectrum faithfully, the width of the slice should be smaller than, or at least comparable to, the homogeneous broadening γ_T. This approach to QD ML laser modeling is much more complex than the simpler one ignoring the inhomogeneous broadening as presented in Viktorov et al. (2006), but is also much more accurate. Its computational efficiency is comparable to that of using the analytical dielectric permittivity (Equations 32.52 through 32.54). Indeed, on the one hand, the number of variables characterizing carrier polarization (gain and refractive index modulation) at each point is not just the carrier density but the populations of the individual levels, but on the other hand, polarization relaxation of each individual level is Lorentzian (Equation 32.50), so an easy and efficient integration kernel of the type of Equation 32.44 can be implemented.

The resulting model has been used for mapping stability limits in a mode-locked laser and analysis of pulse shape and chirp (Rossetti et al., 2011a,b), as well as the analysis of the effects of laser cavity geometry (absorber location, cavity reflectivities) (Simos et al., 2013; Xu and Montrosset, 2013), in particular finding the optimum SA length (Xu and Montrosset, 2013).

The microscopic approach of this type can be implemented both in the traveling-wave formalism as in the papers above (particularly with decimation to improve the otherwise problematic numerical efficiency) and in a DDE model, particularly the multisection version (MS-DDE) as discussed in Section 32.3.3 (Rossetti et al., 2011b). With inhomogeneous broadening included, an MS-DDE model was used for the analysis of problems including the peculiarities of ML operation involving both ground- and excited-level transitions (Xu et al., 2012), as well as for modeling-tapered laser structures (Nikitichev et al., 2012), the latter in agreement with both a TWM simulation by the same authors and with experiments.

In Pimenov and Vladimirov (2014), a multilevel approach was presented for a TWM of a "generic" inhomogeneously broadened medium, not necessarily QD. It can be foreseen that potentially, it can be used for lasers with QW and bulk active layers, for example for a short-cavity QW laser where transitions from both first and second electron levels (disregarded in Equations 32.52 through 32.54) can become important. In principle, it could allow an arbitrary set of carrier density-dependent spectra, possibly calculated using a many-body approach and/or using realistic QW parameters such as multiple-level transitions, strain, etc., by necessity omitted in Equations 32.52 through 32.54, to be approximated and reproduced in the time-domain model. To a degree, the analytical spectrum approach (Equations 32.52 through 32.54) offers such an approximation possibility as well by treating the effective masses of carriers and matrix elements as fitting parameters, which has the advantages of involving much fewer parameters, but may be somewhat less flexible.

32.5.2 Improving the Numerical Efficiency of TWMs: Decimation/Space–Time Folding

So far, we have considered, on the one hand, the DDE models (Section 32.3.3) which are simple, efficient, instructive, and allow automated bifurcation analysis by numerical continuation and in the simplest cases also analytical insight, but are not always accurate in reproducing the behavior or realistic edge-emitting laser constructions, and, on the other hand, full TWM models (Section 32.3.4) which are potentially very accurate in representing a realistic laser, but rather computationally intensive and incompatible with automated bifurcation analysis.

The numerical technique of decimation presented below, which builds on an earlier model for laser designs where gain and SA dispersion are negligible compared to the effect of a lumped dispersive element (reflector) such as a DBR (Vladimirov et al., 2009) to apply to the general case of significant gain and SA dispersion (Javaloyes and Balle, 2012b), allows the advantages of both models to be combined to a large degree.

The starting point for the technique is a TWM in the general form of Equation 32.40, which can be compactly rewritten (keeping only the deterministic part so far) as

$$\pm\frac{\partial Y_{\pm}}{\partial z}+\frac{1}{v_{\mathrm{g}}}\frac{\partial Y_{\pm}}{\partial t}=Z_{\pm}=P_{\pm}^{t}-\alpha_{\mathrm{f}}Y_{\pm}, \tag{32.57}$$

where $\alpha_{\mathrm{f}}=\alpha_{int}/2$ is the "field" internal loss, and the "total" polarization $P_{\pm}^{t}$ includes the dynamic coupling terms:

$$P_{\pm}^{t}=\left(\frac{1}{2}\hat{g}_{\mathrm{mod}}+ik_{\mathrm{ref}}\widehat{\Delta\eta}_{\mathrm{mod}}\right)Y_{\pm}+i\hat{K}_{\pm,\mp}Y_{\mp}. \tag{32.58}$$

(Note that the dynamic coupling terms can include dispersion in the same way as the "copropagating" polarization terms, as is indeed the case in the semimicroscopic model used in Javaloyes and Balle (2010a,b), though this is not likely to have a major effect as the dynamic coupling is usually weak anyway.) The formal solution of Equation 32.51 is obtained in the form

$$Y_{\pm}(z,t)=Y_{\pm}(z\mp v_{\mathrm{g}}\tau,t-\tau)+\Xi_{\pm}(z,t);\quad \Xi_{\pm}(z,t)=\int_{0}^{\tau}Z_{\pm}(z\mp v_{\mathrm{g}}(\tau-\vartheta),t-\tau+\vartheta)\mathrm{d}\vartheta. \tag{32.59}$$

Then, assuming that the time interval is sufficiently short for the variation of the field along the traveling coordinate $\xi_{\mp}=z\mp v_{\mathrm{g}}t$ to be modest (crucially, no such requirement is made to the variations in z and t *separately*—in short-pulse ML, these can be quite strong due to the steep pulse fronts, but the evolution in the pulse shape as it propagates is relatively gentle meaning that variation along $\xi_{\mp}$ remains gentle), it is possible to approximate $\Xi_{\pm}(z,t)=\frac{v_{\mathrm{g}}\tau}{2}(Z_{\pm}(z\mp v_{\mathrm{g}}\tau,t-\tau)+Z_{\pm}(z,t))$. Then, using a (1,1) Padé approximation $\exp(x)\approx(1+x/2)/(1-x/2)$, one obtains a final formula relating the fields and polarizations at the previous and current points:

$$\left(1+\frac{\alpha_{\mathrm{f}}\tau}{2}\right)Y_{\pm}(z,t)=\left(1-\frac{\alpha_{\mathrm{f}}\tau}{2}\right)Y_{\pm}(z\mp v_{\mathrm{g}}\tau,t-\tau)+\frac{v_{\mathrm{g}}\tau}{2}(P_{\pm}^{t}(z\mp v_{\mathrm{g}}\tau,t-\tau)+P_{\pm}^{t}(z,t)). \tag{32.60}$$

This formula can be, and is, implemented directly in a numerical solver, in which a laser is separated into a number of segments n_{sect} with a length $v_{\mathrm{g}}\tau_{j}, j=1,\ldots,n_{\mathrm{sect}}$.

Accurate calculation of the polarization with the spectrum taken into account still requires a small *temporal* integration step Δt (commensurate with $1/\gamma_{T}$); however, crucially, when using Equation 32.59 as a basis of the numerical procedure, the *spatial* step $v_g\tau_j$ is limited only by the degree of uniformity with the field (roughly speaking, the requirement that $v_g\tau_j \left|g_{\text{mod}\,j}\right| << 1$, $g_{\text{mod}j}$ being the characteristic value of the modal gain (or absorption) in the section of the laser with the length $v_g\tau_j$). This is a much less stringent requirement, meaning that the space and time steps are essentially decoupled and the computational time therefore scales, not as $1/\Delta t^2$ as in the straightforward TWM, but only approximately as $1/\Delta t$.

From the numerical point of view, it is important to have an integer relation between the time and space steps:

$$\tau_j = n_{dj}\Delta t, \tag{32.61}$$

where the integer number n_{dj} is the *decimation factor* of the spatial section *j*. It is not necessary (nor advisable) for all the sections to have the same decimation factor; e.g., typically, in the SA part of a passively or hybridly mode-locked laser (where the field is less uniform), it is advisable to set the decimation factor smaller than in the more uniform gain sections. For numerical simplicity, identical decimation factors are typically used in all gain sections and in all SA sections, e.g., $n_{d(\text{gain})} = 71$ and $n_{d\text{SA}} = 8$ were used in Tandoi et al. (2013). This implies that the computation time required in a model with decimation is only a few percent of the time needed for the same calculation with a straightforward TWM model, which is indeed the case.

Mathematically speaking, a model with decimation is a set of n_{sect} delayed algebraic equations (DAEs) with the delay of $\tau_j = n_{dj}\Delta t$ in each section *j*. This section replaces having to deal with n_{dj} spatial steps which would be the case in a straightforward TWM analysis, which is why the alternative (original) term for the decimation technique is *folding space into time delay*. As the number of the DAEs in a typical simulation is not large ($<\sim 10$), the decimated model, unlike a straightforward TWM, is compatible with the numerical tools for bifurcation analysis.

The decimation/space-time folding technique of Tandoi et al. (2013) was not the first attempt at improving the efficiency of the traveling-wave solver. For example, this was attempted, with some degree of success, in the semianalytical TWM technique by Carroll et al. (Jones et al., 1995; Carroll et al., 1998), in which, however, the (homogeneous broadening type) digital filter was explicitly incorporated into the solver and the condition $\Delta z = v_g\Delta t$, eliminated in the decimated TWM, still stood. The decimation technique is thus both much more powerful and more versatile in that it can be used with *any arbitrary method* of calculating the polarization $P_\pm^t$, including either of the two microscopic approaches discussed in Section 32.5.1, or indeed a phenomenological two-level type dispersion representation of Equation 32.44.

However, the decimation technique is both particularly useful and particularly instructive with the analytical kernel technique of Equations 32.54 and 32.57, for which it was originally derived and used (which is the reason we have chosen to place the description of the model within the section on microscopic input). Figure 32.14 illustrates the "stencils" showing the time and space points required for propagating the fields in three major cases: (1) the TWM with a homogeneously broadened line (Figure 32.14a), (2) a straightforwardly implemented TWM with the analytical kernel (Figure 32.14b), and (3) the decimated model with the same analytical kernel and $n_{d(\text{gain})} = 8$, $n_{d\text{SA}} = 2$ (Figure 32.14c). The sparsity of the stencil clearly shows how the decimation allows the sophistication of the microscopic model to be retained while drastically improving the efficiency of the calculation.

We note, following Javaloyes and Balle (2012b), that the decimated TWM contains as particular cases the two other major model types discussed in previous sections. Indeed, with $n_{d(\text{gain})} = n_{d\text{SA}} = 1$, it reduces to a straightforward TWM of Section 32.3.4. For a unidirectional ring cavity (and particularly for a homogeneously broadened line), it reproduces the DDE approach of Section 32.3.3 (Javaloyes and Balle (2012b) noted also that for a single-frequency laser, their model can, in principle, reduce to a generalized complex rate equations formalism, but that is by definition not relevant for ML). A decimated TWM with an analytical kernel technique for gain/refractive index dispersion has been implemented to include a number of laser geometries including but not restricted to mode-locked lasers, and is available online as free software (MATLAB® toolkit) under GPL license (Javaloyes and Balle, 2012a).

32.6 Some Novel Problems and Challenges in Mode-Locked Laser Modeling

32.6.1 Coherent Population Effects as a Possible Saturable Absorption Mechanism

One of the most important developments in mode-locked semiconductor laser technology in the recent years has been the direct generation of ultrashort (tens to a couple of hundreds of femtoseconds) pulses that until recently have been the domain of solid-state lasers only. Only one type of semiconductor lasers has been reported to produce such pulses so far, namely an optically pumped VECSEL, with the gain and SESAM chips in a folded (V-shaped) external cavity arrangement (Klopp et al., 2009, 2011; Quarterman et al., 2009; Wilcox et al., 2008). One of the teams that produced the femtosecond ML pulses attributed their results to coherent effects in the SESAM elements, namely the optical (ac) Stark effect. This effect, related to self-induced transparency, has the relaxation rate equal to the inverse of the dephasing (coherence decay) time. In semiconductors, this time is determined by carrier–carrier (and carrier–phonon) collisions and is of the order of 50–100 fs. This belongs to the *fast*, rather than slow, absorber regime, when the SA recovery time is shorter than the pulse duration. Indeed, theoretical analysis (Mihoubi et al., 2008; Wilcox et al., 2008), based on iterative small-signal time domain approach not dissimilar to that covered in Section 32.3.1 for a standard SA, showed that the pulse duration possible with this mechanism is about twice the dephasing time, which agrees well with the experiments. Further developments of this work are ongoing and are likely to rely not only on the experimental progress but also achieving better understanding of the limits and the requirements on the laser model through improved modeling.

There has also been work recently on the theoretical analysis of (so far, hypothetical) coherent ML through self-induced transparency effects in an *edge-emitting* class B (possibly semiconductor) laser geometry (see, e.g., Arkhipov et al., 2015a, 2016a,b), which promises femtosecond pulses but relies on *extending* the phase relaxation time, possibly by working under cryogenic conditions.

32.6.2 Spontaneous ML in Single-Section Lasers

Most of the discussions above concerned passive or hybrid ML constructions including an SA. However, in recent years, a very interesting development in ML laser technology occurred, when several teams have observed—and utilized—ML in single-section lasers without SA sections and without any external modulation either. The ML in this case was not of a pure AM ML type and the laser output only acquired short-pulse characteristics after external chirp compensation.

This effect has been observed in *quantum dash* (see, e.g., Duan et al., 2009; Gosset et al., 2006; Rosales et al., 2011), *QD* (Lu et al., 2011; Renaudier et al., 2005), QW (Sato, 2003; Yang, 2011), and even bulk materials (Yang, 2011), as well as in intersubband, far-infrared quantum cascade lasers (Faist et al., 2016 and references therein) showing that the effect is fairly generic. Further optimization of these lasers may partly depend on the establishment of full understanding of their behavior, yet at the time of writing, a full, universally agreed, theoretical explanation for ML in single-section lasers is still pending, and it is not impossible that different effects can play the main part in different constructions. In the past, some authors (Shore and Yee, 1991; Yee and Shore, 1993) used frequency-domain models with postulated, and differing, self- and cross- nonlinearity coefficients to show that nonlinearities in single-section semiconductor lasers could lead to a steady-state regime with fixed phases; this was predicted to produce, not the AM ML that corresponds to short-pulse emission, but the so-called frequency modulation ML, in which the phases of adjacent modes differ approximately by π, and the outcome is a CW-like regime with periodic carrier frequency oscillation. More recent works (Nomura et al., 2002; Renaudier et al., 2007), also using frequency-domain analysis with microscopically calculated (Nomura et al., 2002) or phenomenological (Renaudier et al., 2007) description of linear and nonlinear gain, predicted a possibility of ML-type signal generation, including AM ML for certain cavity lengths and active layer parameters, in a single-section laser with three modes involved in lasing, due to mode coupling by population pulsations/four-wave mixing effects. This appears to agree with traveling-wave modeling (Section 32.3.4) analysis for the case of a DBR laser without an SA (Bardella and Montrosset, 2005); Bardella and Montrosset (2005) also identified the role of four-wave mixing in their construction. Recently, a microscopic TWM analysis of a *QD* single-section laser has been presented (Gioannini et al., 2015), relying on both the nonequilibrium occupation of multiple levels due to inhomogeneous broadening and an additional phenomenological gain compression coefficient. The authors concluded that the suppressed carrier diffusion and the fast ground state (GS) gain recovery, typical of quantum dashes and QDs, were the mechanisms behind the phase-locking among the laser modes. Time-domain modeling on single-section ML (comb generation) in quantum cascade lasers has also been reported (Tzenov et al., 2016), though it has to be noted that the short upper state lifetime in those lasers makes their dynamics very different to that of other semiconductor lasers.

Further work extending the understanding achieved this far to other active media is desirable and hopefully forthcoming.

32.7 Concluding Remarks

We have attempted to review the most important developments in semiconductor mode-locked laser modeling. The topic is very dynamic and fast developing, so the choice of emphasis in this review was by necessity subjective; we apologize to those authors whose work may not have been given due prominence.

33.1 Introduction

Quantum cascade lasers (QCLs) are high-power, coherent light sources emitting in the mid-infrared (mid-IR) and terahertz (THz) frequency ranges [1]. QCLs are electronically driven, unipolar devices whose active core consists of tens to hundreds of repetitions of a carefully designed stage. The QCL active core can be considered a superlattice (SL) in which each stage is a multiple quantum well (MQW) heterostructure where confined electronic states with specific energy levels are formed because of quantum confinement. The concept of achieving lasing in semiconductor SLs was first introduced by Kazarinov and Suris [2] in 1971. The first working QCL was demonstrated by Faist et al. [1] two decades later.

QCLs are typically III-V material systems grown on GaAs or InP substrates. Molecular beam epitaxy (MBE) [3] and metal-organic chemical vapor deposition (MOCVD) [4] are the techniques that enable precise growth of thin layers of various III-V alloys. It is also possible to incorporate strain into the structure as long as the total strain in a stage is balanced. Both the precision and the possibility of introducing strain bring great flexibility to the design of the QCL active core, so lasing over a wide range of wavelengths (from 3 to 190 μm) has been achieved. The growth techniques produce high-quality interfaces with atomic-level roughness.

Mid-IR QCLs (wavelength range 3–12 μm) have widespread military and commercial applications. A practical portable detector requires mid-IR QCLs to operate at room temperature (RT) in continuous wave (CW) mode and with high (watt-level) output power. Furthermore, these QCLs must also have high wall-plug efficiency (WPE) (the ratio of emitted optical power to the electrical power pumped in) and long-term reliability under these high-stress operating conditions. As the stress likely stems from excessive nonuniform heating while lasing [5,6], improving device reliability and lifetime goes hand in hand with improving the WPE.

33.1.1 Lasing in QCLs

In QCLs, multiple conduction subbands are formed in the active core by means of quantum confinement. QCLs are unipolar devices, meaning that lasing is achieved through radiative intersubband transitions (transitions between two conduction subbands) instead of radiative interband transitions (transitions between the conduction and valence bands) in traditional quantum well (QW) semiconductor lasers. As a result, electrons do not combine with holes after the radiative transitions and can be used to emit another photon. In order to reuse electrons, the same MQW heterostructure is repeated many times (25–70) in the QCL active core (the so-called cascading scheme).

Figure 33.1 depicts a typical conduction band diagram of two adjacent stages in a QCL under an electric field. Each stage consists of an injector region and an active region. The injector region has several thin wells separated by thin barriers (10–30 Å), so a miniband is formed with multiple subbands that are close in energy and whose associated wavefunctions have high spatial overlap. Typically, the lowest few energy levels in the miniband are referred to as the injector levels. The injector levels collect the electrons that come from the previous stage and inject them into the active region. The active region usually consists of 2–3 wider wells (40–50 Å) separated by thin barriers. Consequently, a minigap forms in the active region between the upper lasing level (3) and the lower lasing level (2). Another important energy level in the active region is the ground state (1). There is a thin barrier (usually the thinnest among all layers) between the injecting region and the active region, called the injection barrier.

By design, the injector levels are close in energy and strongly coupled to the upper lasing level because of the thin injection barrier. The upper and lower lasing levels have large spatial overlap, which allows a radiative transition between the two levels; the wavelength of the emitted light is determined by the energy spacing between these two levels. The lower lasing level overlaps with the ground state for efficient electron extraction. Electron emission of longitudinal optical (LO) phonons is the dominant mechanism for electron extraction, so the energy spacing between the lower lasing level and the ground state is designed to be close to the LO phonon energy to facilitate extraction. With careful design, the electron lifetime in the upper lasing level is longer than in the lower lasing level, so population inversion can be

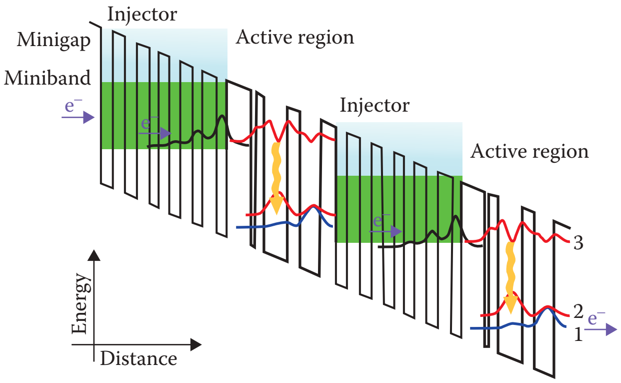

FIGURE 33.1 A typical conduction band diagram of two adjacent QCL stages under an applied electric field. Each stage consists of an injector region and an active region. A miniband is formed in the injector region while a minigap is formed in the active region (between the upper and lower lasing levels). Lasing is associated with a radiative transition from the upper (3) to the lower (2) lasing level. Electrons in the lower lasing level depopulate quickly to the ground level (1) by emission of longitudinal optical phonons.

achieved. After reaching the ground state, electrons tunnel through the injector into the upper lasing level of the next stage, and the process is repeated. Of course, the lasing mechanism description above is idealized. In reality, the efficiency of the radiative transition between the upper and lower lasing levels is very low [7,8].

33.1.2 Recent Developments in High-Power QCLs

In recent years, considerable focus has been placed on improving the WPE and output power of QCLs for RT CW operation. Bai et al. [9] showed 8.4% WPE and 1.3 W output power around 4.6 μm in 2008. Shortly thereafter, Lyakh et al. [10] reported 12.7% WPE and 3 W power at 4.6 μm. Watt-level power with 6% WPE at 3.76 μm and then lower power at 3.39 and 3.56 μm are reported by Bandyopadhyay et al. [11,12]. Bai et al. [13] demonstrated 21% WPE and 5.1 W output power around 4.9 μm in 2011. Much higher WPE and/or output power has been achieved at lower temperatures or at pulsed mode [7,14] near 4.8 μm. A summary of recent developments can be found in review papers [8,15].

While good output powers and WPEs have been achieved, long-term reliability of these devices under RT CW operation remains a critical problem [5,6]. These devices are prone to catastrophic breakdown owing to reasons that are not entirely understood, but are likely related to thermal stress that stems from prolonged high-power operation [5]. This kind of thermal stress is worst in short-wavelength devices that have high strain and high thermal-impedance mismatch between layers [11,12,16,17].

In addition to improved device lifetime, we seek better CW temperature performance (higher characteristic temperatures T_0 and T_1, defined next) [6]. The first aspect is a weaker temperature dependence of the threshold current density. Empirically, the threshold current density (the current density at which the device starts lasing) has an exponential dependence on the operating temperature T: $J_{\mathrm{th}} \propto \exp\left(\frac{T}{T_0}\right)$. Higher characteristic temperature T_0 is preferred in QCL design, as it means less variation in J_{th} as the temperature changes.

Another key temperature-dependent parameter is the differential quantum efficiency (also called the slope efficiency or external quantum efficiency), defined as the amount of output optical power dP per unit increase in the pumping current dI: $\eta_{\mathrm{d}} = \frac{\mathrm{d}P}{\mathrm{d}I} \propto \exp\left(-\frac{T}{T_1}\right)$. The differential quantum efficiency is directly proportional to the WPE ($\mathrm{WPE} = \eta_{\mathrm{d}}\eta_{\mathrm{f}}$, where η_{f} is the feeding efficiency). Therefore, the higher the T_1, the closer the η_{d} is to unity, and the higher the WPE. Recently, deep-well structures with tapered active regions have demonstrated significant improvements in T_0 and T_1 with respect to the conventional 4.6-μ*m* device [9], underscoring that the suppression of leakage plays a key role in temperature performance [6,18,19]. Still, the microscopic mechanisms and leakage pathways that contribute to these empirical performance parameters remain unclear.

33.1.3 QCL Modeling: An Overview

Under high-power RT CW operation, both electron and phonon systems in QCLs are far away from equilibrium. In such nonequilibrium conditions, both electronic and thermal transport modeling are important for understanding and improving QCL performance.

Electron transport in both mid-IR and THz QCLs has been successfully simulated via semiclassical (rate equations [20–22] and Monte Carlo [23–26]) and quantum techniques (density matrix [27–33], nonequilibrium Green's functions (NEGF) [34–36], and lately Wigner functions [37]). InP-based mid-IR QCLs have been addressed via semiclassical [38] and quantum transport approaches (8.5-μm [39] and 4.6-μm [35,36] devices). There has been a debate whether electron transport in QCLs can be described using semiclassical models, in other words, how much of the current in QCLs is coherent. Theoretical work by Iotti and Rossi [23,40] shows that the steady-state transport in mid-IR QCLs is largely incoherent. Monte Carlo simulation [41] has also been used to correctly predict transport near threshold. However, short-wavelength structures [9] have pronounced coherent features, which cannot be addressed semiclassically

[33]. NEGF simulations accurately and comprehensively capture quantum transport in these devices but are computationally demanding. Density matrix approaches have considerably lower computational overhead than NEGF but are still capable of capturing coherent transport features. A comprehensive review of electron transport modeling was recently written by Jirauschek and Kubis [42].

Electronic simulations that ignore radiative transitions are applicable for modeling QCLs below or near threshold where the interaction between electrons and the laser electromagnetic field can be ignored. Such simulations are useful for predicting quantities such as threshold current density and T_0. However, in order to accurately model QCLs under lasing operations, the effect of the laser field on electronic transport would have to be included. In some cases, the effects of the laser field can be very strong [39], especially for high-WPE devices, where the field-induced current can be dominant [38]. When included in simulations, the laser field is typically modeled either as an additional scattering mechanism [38,43] or as a time-dependent sinusoidal electric field [39,44]. In this work, we ignore the effect of the laser field on electron dynamics.

Thermal transport in QCLs is often described through the heat diffusion equation, which requires accurate thermal conductivity in each region, a challenging task for the active core that contains many interfaces [17,45–48]. It is also very important to include nonequilibrium effects, such as the nonuniform heat generation rate stemming from the nonuniform temperature distribution [47] and the feedback that the nonequilibrium phonon population has on electron transport [26].

In this chapter, we present a multiphysics (coupled electronic and thermal transport) and multiscale (bridging between a single stage and device level) simulation framework that enables the description of QCL performance under far-from-equilibrium conditions [49]. We present the electronic (Section 33.2) and thermal (Section 33.3) transport models, and then bring them together for electrothermal simulation of a real device structure (Section 33.4). We strive to cover the basic ideas while pointing readers to the relevant references for derivation and implementation details.

33.2 Electronic Transport

Depending on the desired accuracy and computational burden, one can model electronic transport in QCLs with varying degrees of complexity. The goal is to determine the modal gain (proportional to the population inversion between the upper and lower lasing levels) under various pumping conditions (current or voltage) and lasing conditions (pulsed wave or CW). A typical electron transport simulator relies on accurately calculated quasibound electronic states and associated energies in the direction of confinement. Electronic wavefunctions and energies are determined by solving the Schrödinger equation or the Schrödinger equation combined with the Poisson's equation in highly doped systems. Section 33.2.3.1 introduces a $\mathbf{k} \cdot \mathbf{p}$ Schrödinger solver coupled with a Poisson solver. More information about other solvers for electronic states can be found in the review paper [42] and references therein.

The simulations of electronic transport fall into two camps depending on how the electron single-particle density matrix is treated. The diagonal elements of the density matrix represent the occupation of the corresponding levels and off-diagonal elements represent the "coherence" between two levels. Transport is semiclassical or incoherent when the off-diagonal coherences are much smaller than the diagonal terms and can be approximated as proportional to the diagonal terms times the transition rates between states [50]. In that case, the explicit calculation of the off-diagonal terms is avoided and only the diagonal elements are tracked, which simplifies the simulation considerably. However, when the off-diagonal terms are appreciable, transport is partially coherent and has to be addressed using quantum transport techniques.

33.2.1 Semiclassical Techniques

Semiclassical approaches assume that electronic transport between stages is largely incoherent "hopping" transport. The key quantities are populations of electronic states that are confined in the QCL growth direction, and electrons transfer between them due to scattering events. The scattering rates can be obtained empirically or more rigorously via Fermi's golden rule. Common semiclassical approaches are the rate equations and ensemble Monte Carlo (EMC), the latter solving a Boltzmann-like transport equation stochastically.

33.2.1.1 Rate Equations

In the rate equation approach [20–22], scattering between relevant states, i.e., the injector level, the upper and lower lasing levels, and the ground state, is captured through transition rates. The rates include all relevant (radiative and nonradiative) scattering mechanisms and can be either empirical parameters or calculated [51,52]. The computational requirements of rate equation models are low, so they are suitable for fast numerical design and optimization of different structures [22].

33.2.1.2 Ensemble Monte Carlo

The heterostructure in the QCL active core is a quasi-two-dimensional (quasi-2D) system, where electrons are free to move in the x–y plane, while confined cross-plane in the z direction; the confinement results in the formation of quasibound states and discrete energy levels corresponding to the bottoms of 2D energy subbands. The electron wavefunctions in 3D are plane waves in the x–y plane and confined wavefunctions in z direction. Electronic transport is captured by a Boltzmann-like semiclassical transport equation [23], which can be solved via the stochastic EMC technique assuming instantaneous hops between states in 3D due to scattering [53]. The simulation explicitly tracks the energy level and in-plane momentum of each particle in the simulation ensemble (typically $\sim 10^5$ particles). Tracking in-plane dynamics makes it more detailed than the rate equation model. The transition rates are generally computed directly from the appropriate interaction Hamiltonians and therefore depend on the energy levels as well as the wavefunction overlaps between different electronic states [42,53,54]. EMC allows us to include nonequilibrium effect into transport, which is covered in more detail in Section 33.2.3.

33.2.2 Quantum Techniques

Density matrix and NEGF are the two most widely used techniques to describe quantum transport in QCLs. Recently, a Wigner function approach was also successfully used to model a SL [37].

33.2.2.1 Density Matrix Approaches

In semiclassical approaches, the central quantity of interest is the distribution function $f_n^{E_\mathrm{k}}(t)$, the probability of an electron occupying an eigenstate n and having an in-plane kinetic energy E_k. The quantum-mechanical analogue is the single-electron density matrix, $\rho_{nm}^{E_\mathrm{k}}(t)$, where the diagonal elements $\rho_{nn}^{E_\mathrm{k}}(t) = f_n^{E_\mathrm{k}}(t)$ are occupations and the off-diagonal elements $\rho_{nm}^{E_\mathrm{k}}(t)$ are the spatial coherences between states n and m at the in-plane energy E_k. When employing semiclassical methods, off-diagonal matrix elements are assumed to be much smaller than diagonal elements. This approximation may fail in some cases, e.g., when two eigenstates with a large spatial overlap have similar energies. This scenario often arises when modeling THz QCLs [28,32,55], but can also come up in mid-IR QCLs [33]. In these cases, semiclassical models fail.

The density matrix models that have been employed for QCL modeling can be categorized into two groups. The first includes hybrid methods, where transport is treated semiclassically within a region of the device (typically a single stage) while the effects of tunneling between different regions, separated by barriers, are treated quantum mechanically using a density matrix formalism with phenomenological dephasing times [28,31,55]. The second group involves completely quantum-mechanical methods that rely on microscopically derived Markovian master equations that guarantee positivity of the density matrix [32,33]. Both methods are more computationally expensive than their semiclassical counterparts, because the density matrix contains many more elements than its diagonal semiclassical analogue.

33.2.2.2 Nonequilibrium Green's Functions

The NEGF technique (see a good overview in Reference [42]) relies on the relationships between single-particle time-ordered Green's functions and correlation functions [34–36]. The correlation function $G^{<}_{\alpha,\beta}(k;t_1,t_2)$, often referred to as the lesser Green's function [44,56], is one of the central quantities and can be understood as a two-time generalization of the density matrix, where k refers to the magnitude of in-plane wave vector. The correlation function contains both spatial correlations (terms with $\alpha \neq \beta$) as well as temporal correlations between times t_1 and t_2 (not included in semiclassical or density matrix models). Typically, the potential profile is assumed to be time independent, in which case the correlation function only depends on the time difference $G^{<}_{\alpha,\beta}(k;t_1,t_2) = G^{<}_{\alpha,\beta}(k;t_1 - t_2)$. Fourier transform over the time difference into the energy domain gives the energy-resolved correlation function $G^{<}_{\alpha,\beta}(k,E)$, which is the quantity that is usually solved for numerically [35,44,56]. The main advantages of the NEGF formalism are that it provides spectral (energy-resolved) information and it includes the effects of collisional broadening (the broadening of energy levels due to scattering), which is particularly important when the states are close in energy. These advantages carry a considerable computational cost, so NEGF calculations are much more time-consuming than density matrix approaches [39].

33.2.3 EMC with Nonequilibrium Phonons

Here, we focus on presenting semiclassical modeling of electron transport in QCL structures via EMC [25,26,57]. The solver consists of two parts: a coupled Schrödinger–Poisson solver and a transport kernel. We solve for the electronic states using the coupled Schrödinger–Poisson solver and feed the energy levels and the wavefunctions of the relevant electronic states to the transport kernel. The transport kernel keeps track of the electron momentum, energy, and distribution among subbands. If the electron density inside the device is high, transport kernel will periodically feed the electron distribution back to the Schrödinger–Poisson solver and update the electronic states. This loop is repeated until the electron distribution converges. By doing so, we solve for both the electron transport and the electronic band structure self-consistently.

Since the active QCL core consists of repeated stages, the wavefunctions in any stage can be obtained from the wavefunctions in any other stage by translation in space and energy. This translational symmetry makes it possible to simulate electron transport in only one generic central stage instead of in the whole QCL core [53]. Typically, electronic states in nonadjacent stages have negligible overlap, which also means that the transition rates between them are negligible. As a result, it is sufficient to limit interstage scattering events to only those between adjacent stages.

Figure 33.2 shows a schematic of three adjacent stages under an applied field. We simulate electron transport in the central stage λ, while nearest-neighbor interstage ($\lambda \rightleftarrows \lambda \pm 1$) and intrastage ($\lambda \to \lambda$) scattering is allowed. Periodic boundary conditions (PBCs) are applied in the simulation, i.e., whenever one electron scatters from the central stage into the next stage (process ②), an electron scatters from the previous stage into the central stage (process ①) and vice versa (process ③ and process ④). PBCs are justified by the cascading scheme.

33.2.3.1 Electronic Bandstructure Solver

We employ the **k·p** method to solve the Schrödinger equation and couple it to a Poisson solver [25,53,57]. The **k·p** method is an efficient way to solve for the electronic band structure near the band edges, where the transport happens in QCLs. The **k·p** method considers the contribution from the conduction band (C), light-hole band (LH), and the spin-orbit split-off band (SO) (the heavy-hole band (HH) decouples from the other three at the band edge) [58]. The contributions from the LH and SO are especially important for narrow-gap materials, such as InP. Moreover, in modern QCLs, strain-balanced structures have been employed to obtain enhanced performance. In these structures, alternate layers are compressively or tensilely strained while the whole structure is strain free, with carefully designed thickness of each

layer. The **k·p** method allows for convenient inclusion of the effects of strain on the band structure. The implementation details of the **k·p** solver can be found in Reference [53].

The **k·p** solver can only solve for a finite structure rather than an infinite periodic one. As a result, we need to simulate a finite number of stages and add artificially high barriers to the two ends to confine all the states. If a stage is far enough from the boundaries, the calculated band structure in it should be the same as if we were to solve for the whole periodic structure. Tests have confirmed that three stages, which we also used in EMC, are enough when solving for the electronic states to ensure that the central-stage states are unaffected by the simulation-domain potential boundaries. The states from the central stage are then translated in energy and position to the neighboring stages according to the stage length and the applied electric field.

When we need to solve for electron transport and electronic states self-consistently, it is necessary for the solver to be able to automatically pick out the electronic states belonging to the central stage. One intuitive criterion is to calculate the "center of mass" for each state (the expectation value of the cross-plane coordinate, $\langle z \rangle$) and assign those falling in the central stage to that stage. However, in our three-stage scheme, this method may pick up the states that are too close to the boundary. One can either extend the number of stages in the **k·p** solver to five, so the three stages in the middle are all far from the boundary, or use additional criteria such as that there be more than 50% possibility of finding an electron in the central stage, based on the probability density distribution, or requiring that the location of the probability density peak be in the central stage. Additional criteria requiring strong confinement of states have been explored in [32].

33.2.3.2 Transport Kernel with Nonequilibrium Phonons

The EMC kernel tracks the hopping transitions of electrons between subbands and stages until convergence and outputs the transport information for us to calculate the experimentally relevant quantities such as current and modal gain [53]. In the transport kernel, both electron–electron interactions and electron–LO-phonon interactions are considered. Other scattering processes, such as intervalley scattering, impurity scattering, and interface roughness scattering can be considered under different circumstances [42]. Photon emission is not considered, either. Because EMC tracks individual particles, nonequilibrium electron transport can be automatically captured. (EMC tracks individual simulation particles, each of which might represent thousands of real electrons.)

The most important scattering mechanism in QCLs is electron–LO-phonon scattering, which facilitates the depopulation of the lower lasing level. As shown in Reference [59], phonon confinement has little effect on the electronic transport; therefore, for simplicity, LO phonons are treated as bulklike dispersionless phonons with energy $\hbar\omega_0$. The transition rate between an initial state $\phi_i(z)$ with energy E_i and a final state $\phi_f(z)$ withenergy E_f can be derived from the Fermi's golden rule as follows:

$$\Gamma_{a(-),e(+)} = \frac{e^2\hbar\omega_0 m_f^*}{8\pi^2\hbar^3}\left(\frac{1}{\epsilon_\infty}-\frac{1}{\epsilon_0}\right)\int_0^{2\pi} d\theta \int_{-\infty}^{\infty} dq_z \int_0^{\infty} dE_{kf} N_{\mathbf{q}} \frac{|\mathcal{I}_{\mathrm{if}}(q_z)|^2}{\mathbf{q}_{\|}^2 + q_z^2}\delta(E_f - E_i \mp \hbar\omega_0), \qquad (33.1)$$

where e is the electronic charge while ϵ_0 and ϵ_∞ are static and high-frequency electronic permittivities of the material, respectively. The integrals are over the in-plane kinetic energy E_k of the final state and the cross-plane momentum transfer q_z. $\mathbf{q}_{\|} = \mathbf{k}'_{\|} - \mathbf{k}_{\|}$ is the in-plane momentum transfer.

$$|\mathcal{I}_{\mathrm{if}}(q_z)|^2 = \left| \int_0^d dz \phi_f^*(z)\phi_i(z)e^{-izq_z} \right|^2 \qquad (33.2)$$

is defined as the overlap integral (OI) between the initial and final states, where q_z is the cross-plane momentum transfer. The integration is over the angle between initial and final in-plane momenta $\mathbf{k}_{\|}$ and $\mathbf{k}'_{\|}$ (θ), cross-plane momentum component of the final state (k_{fz}), and the kinetic energy of the final state (E_{kf}). $N_{\mathbf{q}}$ represents the number of LO phonons with momentum $\mathbf{q} = (\mathbf{q}_{\|}, q_z)$. The expression can be further simplified in the equilibrium case, where $N_{\mathbf{q}}$ follows the Bose–Einstein distribution [53]. In order to model nonequilibrium phonon effects, we numerically integrated the expression using a phonon number histogram according to both $q_{\|}$ and q_z [54].

According to the uncertainty principle, position and momentum both cannot be determined simultaneously. Since our electrons are all confined in the central stage ($\Delta z'$ is finite), the cross-plane momentum is not exactly conserved during the scattering process ($q_z \neq k'_z - k_z$) [60]. This analysis does not affect the momentum conservation in the x–y plane, because we assume infinite uncertainty in position there. Previously, the cross-plane momentum conservation has been considered through the momentum conservation approximation (MCA) [61,62] and a broadening of q_z according to the well width [60]. The MCA forbids a phonon emitted between subbands i and f to be reabsorbed by another transition between i' and f' if $i \neq i'$ or $f \neq f'$, and thus might underestimate the electron–LO interaction strength [54]. The concept of well width is hard to apply in an MQW structure such as the QCL active core [54]. We observe that the probability of a phonon with cross-plane momentum q_z being involved in an interaction is proportional to the OI in Equation 33.2. Figure 33.3 depicts the typical OIs for both intersubband ($i_1 \rightarrow 3$ and $2 \rightarrow 1$) and intrasubband ($3 \rightarrow 3$) transitions. As a result, in each electron–LO-phonon scattering event, we randomly select a q_z following the distribution from the OI (Figure 33.3). Depending on the mechanism (absorption or emission), a phonon with $(\mathbf{q}_{\|}, q_z)$ is removed or added to the histogram according to the 2D density of states (DOS) and the effective simulation area [54]. Once the phonons with a certain momentum are depleted, transitions involving such phonons become forbidden.

In order to couple the EMC solver to the thermal transport solver, we need to keep a detailed log of heat generation during electron transport. In all the relevant scattering events, electron–LO-phonon scattering is the only inelastic mechanism and therefore is the only mechanism that contributes to heat generation. As a result, the total energy emitted and absorbed in the form of LO phonons is recorded during each step of the EMC simulation. The nonequilibrium phonons decay into acoustic longitudinal acoustic (LA) phonons via a three-phonon anharmonic decay process. The formulation and the parameters here follow [63]. The simulation results of EMC including nonequilibrium phonons are shown in Section 33.4.

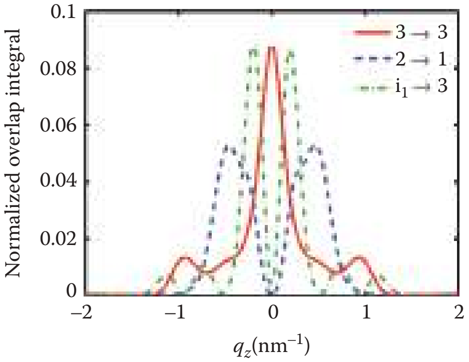

FIGURE 33.3 Normalized overlap integral $|\mathcal{I}_{\text{if}}|^2$ from Equation 33.2 versus cross-plane phonon wave vector q_z for several transitions (intersubband $i_1 \rightarrow 3$ and $2 \rightarrow 1$; intrasubband $3 \rightarrow 3$). 33.3 Thermal Transport

The dominant path of heat transfer in a QCL structure is depicted in Figure 33.4. The operating electric field of a typical QCL is high, which means that considerable energy is pumped into the electronic system. These energetic, "hot" electrons relax their energy largely by emitting LO phonons. LO phonons have high energies but flat dispersions, so their group velocities are low and they are poor carriers of heat. An LO phonon decays into two LA phonons via a three-phonon process referred to as anharmonic decay. LA phonons have low energy but high group velocity and are the main carriers of heat in semiconductors [47,63]. If we neglect the diffusion of optical phonons, the flow of energy in a QCL can be described by the following equations:

$$\frac{\partial W_{\text{A}}}{\partial t} = \nabla \cdot (\kappa_{\text{A}} \nabla T_{\text{A}}) + \left.\frac{\partial W_{\text{LO}}}{\partial t}\right|_{\text{coll}}; \quad \frac{\partial W_{LO}}{\partial t} = \nabla \cdot (\kappa_{\text{A}} \nabla T_{\text{A}}) + \left.\frac{\partial W_{\text{e}}}{\partial t}\right|_{\text{coll}} - \left.\frac{\partial W_{\text{LO}}}{\partial t}\right|_{\text{coll}}, \tag{33.3}$$

where W_{LO}, W_{A}, and W_{e} are the LO phonon, acoustic phonon, and electron energy densities, respectively. κ_{A} is the thermal conductivity in the system and T_{A} is the acoustic phonon (lattice) temperature. The term $\nabla \cdot (\kappa_{\text{A}} \nabla T_{\text{A}})$ describes heat diffusion, governed by acoustic phonons. We have also used the fact that the rate of increase in the LO-phonon energy density equals the difference between the rate of its generation by electron–LO-phonon scattering and the rate of anharmonic decay into LA phonons.

In a nonequilibrium steady state, both the LO and LA energy densities are constant, so

$$-\nabla \cdot (\kappa_{\text{A}} \nabla T_{\text{A}}) = \left.\frac{\partial W_{\text{e}}}{\partial t}\right|_{\text{coll}}. \tag{33.4}$$

As described in the previous section, the right-hand side of Equation 33.4 is the heat generation rate Q and can be obtained by recording electron–LO-phonon scattering events in electronic EMC [47,64]:

$$Q = \left.\frac{\partial W_{\text{e}}}{\partial t}\right|_{\text{coll}} = \frac{N_{\text{3D}}}{N_{\text{sim}} t_{\text{sim}}} \sum (\hbar\omega_{\text{ems}} - \hbar\omega_{\text{abs}}), \tag{33.5}$$

where $N_{\text{3D}} = N_s/D_{\text{stage}}$ is the electron density (N_{s} is the sheet density and D_{stage} is the length of a single stage) while N_{sim} and t_{sim} are the number of simulation particles and the simulation time, respectively,

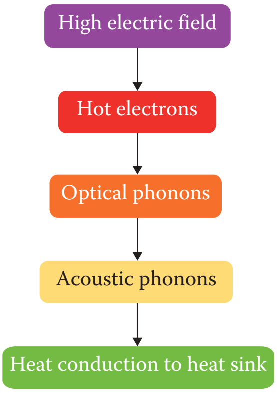

FIGURE 33.4 Flow of energy in a QCL.

and $\hbar\omega_{\text{ems}}$ and $\hbar\omega_{\text{abs}}$ are the energies of the emitted and absorbed LO phonons, respectively. To solve Equation 33.4, we need information on both the thermal conductivity κ_A and the heat generation rate Q; they are discussed in Subsections 33.3.1 and 33.3.2, respectively.

33.3.1 Thermal Conductivity in a QCL Device

33.3.1.1 Active Core: A III-V Superlattice

The QCL active core is an SL: It contains many identical stages, each with several thin layers made from different materials and separated by heterointerfaces. The thermal conductivity tensor of an SL system reduces to two values: the in-plane thermal conductivity $\kappa_{\|}$ (in-plane heat flow is assumed isotropic) and the cross-plane thermal conductivity $\kappa_{\perp}$. Experimental results have shown that, in SLs, the thermal conductivity is very anisotropic [65] ($\kappa_{\|} \gg \kappa_{\perp}$) while both $\kappa_{\|}$ and $\kappa_{\perp}$ are smaller than the weighted average of the constituent bulk materials [66–70]. Both effects can be attributed to the interfaces between adjacent layers [71,72].

Here, we discuss a semiclassical model for describing the thermal conductivity tensor of III-V SL structures. Note that the model described here is in principle applicable to SLs in other material systems as long as they have high-quality interface and thermal transport is mostly incoherent [48,73–75]. In particular, we focus on thermal transport in III-arsenide-based SLs, as they are most commonly used in mid-IR QCL active cores [48].

Under QCL operation conditions of interest (>77 K, and typically near RT), thermal transport is dominated by acoustic phonons and is governed by the Boltzmann transport equation (BTE). To obtain the thermal conductivity, we solve the phonon BTE with full phonon dispersion in the relaxation-time approximation [48].

33.3.1.2 Twofold Influence of Effective Interface Roughness

To capture both the anisotropic thermal transport and the reduced thermal conductivity in SL systems, we need to observe the twofold influence of the interface. First, it reduces $\kappa_{\|}$ by affecting the acoustic phonon population close to the interfaces [76]. Second, it introduces an interface thermal boundary resistance (ITBR), which is still very difficult to model [65,77]. Common models are the acoustic mismatch model (AMM) and the diffuse mismatch model (DMM) [65,76]; the former assumes a perfectly smooth interface and only considers the acoustic mismatch between the two materials, while the latter assumes complete randomization of momentum after phonons hit the interface. As most III-V-based QCLs are

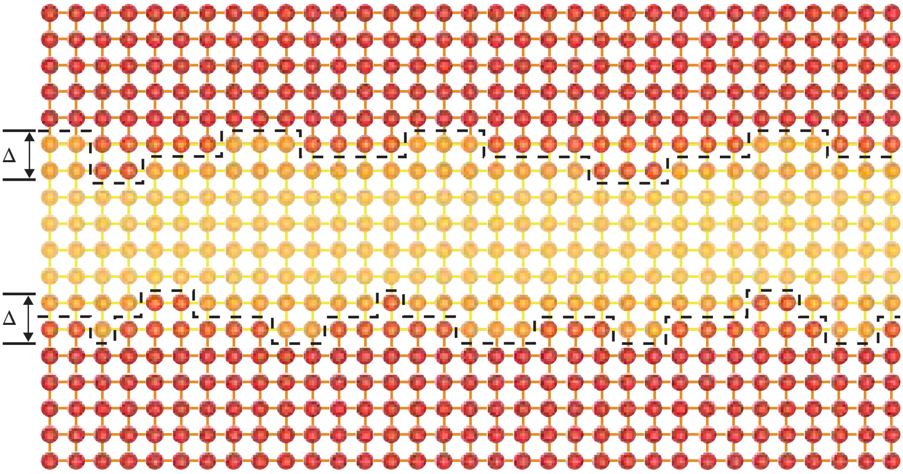

FIGURE 33.5 Even between lattice-matched crystalline materials, there exist nonuniform transition layers that behave as an effective atomic-scale interface roughness with some rms roughness Δ. This effective interface roughness leads to phonon momentum randomization and to interface resistance in cross-plane transport. (From S. Mei and I. Knezevic, *Journal of Applied Physics*, 118, 175101, 2015. With the permission of AIP Publishing.)

grown by MBE or MOCVD, both well-controlled techniques allowing consistent atomic-level precision, neither AMM nor DMM captures the essence of a III-V SL interface. Figure 33.5 shows a schematic of interface roughness in a lattice-matched SL. The jagged dashed boundaries depict transition layers of characteristic thickness Δ between the two materials.

We introduce a simple model that calculates a more realistic ITBR (a key part in calculating $\kappa_\perp$) by interpolating between the AMM and DMM transmission rates using a specularity parameter p_{spec}. The model has a single fitting parameter: the effective interface rms roughness Δ. Since the growth environment is well controlled, using one Δ to describe all the interfaces is justified. We use Δ to calculate a momentum-dependent specularity parameter:

$$p_{\text{spec}}(\vec{q}) = \exp(-4\Delta^2|\vec{q}|^2\cos^2\theta), \tag{33.6}$$

where $|\vec{q}|$ is the magnitude of the phonon wave vector and θ is the angle between $\vec{q}$ and the normal direction to the interface. Consistent with the twofold impact of interface roughness, Δ affects the thermal conductivity through two channels. Apart from calculating the ITBR, an effective interface scattering rate $\tau^{-1}_{\text{interface}}(\vec{q})$ dependent on the same specularity parameter $p_{\text{spec}}(\vec{q})$ is added to the internal scattering rate to calculate modified $\kappa_{\|}$ (see detailed derivations in [48]). By adjusting only Δ, typically between 1 and 2 Å, the calculated thermal conductivity using this model fits a number of different experiments [66,68,69].

33.3.1.3 $\kappa_{\|}$ and $\kappa_\perp$ of a QCL Active Core

Thermal transport inside the active core of a QCL is usually treated phenomenologically: $\kappa_{\|}$ is typically assumed to be 75% of the weighted average of the bulk thermal conductivities of the constituent materials, while $\kappa_\perp$ is treated as a fitting parameter (constant for all temperatures) to best fit the experimentally measured temperature profile [17,78]. We calculated the thermal conductivity tensor of a QCL active core [78] and showed that the typical assumption is not accurate and that the degree of anisotropy is temperature dependent (Figure 33.6).

The ratio between $\kappa_{\|}$ and the averaged bulk value (inset to Figure 33.6) varies between 45% and 70% over the temperature range of interest. $\kappa_\perp$ has a weak dependence on temperature in keeping with the

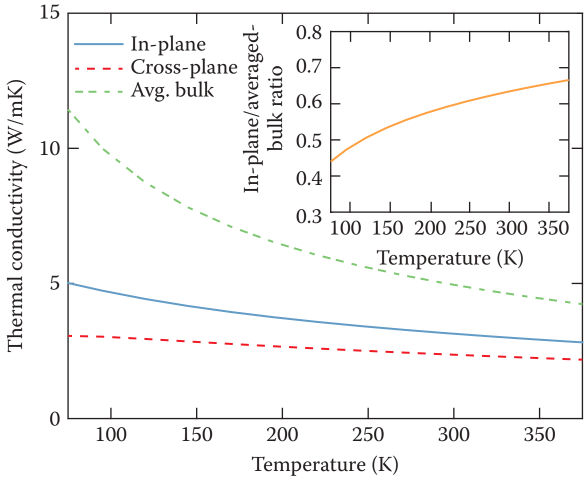

FIGURE 33.6 Thermal conductivity of a typical QCL active region [78] as a function of temperature. A single stage consists of 16 alternating layers of $In_{0.53}Ga_{0.47}As$ and $In_{0.52}Al_{0.48}As$. The solid curve, dashed curve, and dashed-dotted curve show the calculated in-plane, cross-plane, and averaged bulk thermal conductivity, respectively. $\Delta = 1$ Å in the calculations. The inset shows the ratio between the calculated in-plane and the averaged bulk thermal conductivities. (From S. Mei and I. Knezevic, *Journal of Applied Physics*, 118, 175101, 2015. With the permission of AIP Publishing.)

TABLE 33.1 Thermal Conductivity as a Function of Temperature for Materials in a QCL Structure

Materials	Thermal Conductivity (W/mK)
Au	$337–600 \times 10^{-4}T$
Si_3N_4	$30–1.4 \times 10^{-2}T$
In solder	$93.9–6.96 \times 10^{-2}T + 9.86 \times 10^{-5}T^2$

common assumption in simplified models; the weak temperature sensitivity means that ITBR dominates cross-plane thermal transport. These results show that it is important to carefully calculate the thermal conductivity tensor in QCL thermal simulation, and we use this thermal conductivity model in the device-level simulation.

33.3.1.4 Other Materials

The active core is not the only region we need to model in a device-level thermal simulation. Figure 33.7 shows a typical schematic (not to scale) of a QCL device in thermal simulation with a substrate-side mounting configuration [79]. The active core (in this case, consisting of 36 stages and 1.6-µm thick) with width W_{act} is embedded between two cladding layers (4.5-µm-thick GaAs). The waveguide is supported by a substrate (GaAs) with thickness D_{sub}. An insulation layer (Si_3N_4) with thickness D_{ins} is deposited around the waveguide and then etched away from the top to make the contact. Finally, a contact layer (Au) with thickness D_{cont} and a thin layer of solder (D_{sold}) are deposited on top. There is no heat generation in the regions other than the active core. Further, these layers are typically thick enough to be treated as bulk materials. Bulk substrate (GaAs or InP) thermal conductivities are readily obtained for III-V materials from experiment, as well as from relatively simple theoretical models [17,48,78,80] (Table 33.1).

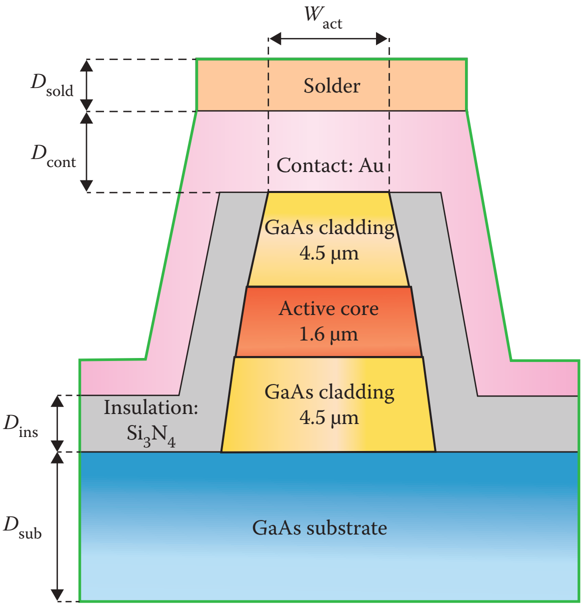

FIGURE 33.7 Schematic of a typical GaAs-based mid-IR QCL structure with a substrate (not to scale).

33.3.2 Device-Level Electrothermal Simulation

33.3.2.1 Device Schematic

The length of a QCL device is much greater than its width, therefore we can assume the length is infinite and carry out a 2D thermal simulation. The schematic of the simulation domain (not to scale) is shown in Figure 33.7. The boundary of the simulation region is delineated, and certain boundary conditions (heat sink at fixed temperature, convective boundary condition, or adiabatic boundary condition) can be applied (independently) to each boundary. Typically, the bottom boundary of the device is connected to a heat sink while other boundaries have the convective boundary condition at the environment temperature (single-device case) or the adiabatic boundary condition (QCL array case). Typical values for the layers thickness are $W_{act} = 15$ μm, $D_{sub} = 50$ μm, $D_{ins} = 0.3$ μm, $D_{cont} = 3$ μm, and $D_{sold} = 1.5$ μm.

We use the finite element method to solve for the temperature distribution. The whole device is divided into different regions according to their materials properties. Each stage of the active region is treated as a single unit with the heat generation rate tabulated in the device table in order to capture the nonuniform behavior among stages. The active core is very small but is also the only region with heat generation, small thermal conductivity, and spatial nonuniformity. To capture the behavior of the active region while saving computational time, we use a nonuniform mesh in the finite element solver to emphasize the active core region. Figure 33.8 shows a mesh generated in the simulation.

33.3.2.2 Simulation Algorithm

It is known that among all the stages in the active core, the temperature T_i and the electric field F_i (i represents the stage index) are not constant [56,78], but we have no *a priori* knowledge of how they depend on the stage index. However, we know that the charge–current continuity equation must hold, and in the steady state $\nabla \cdot \mathbf{J} = 0$; this implies that the current density J must be uniform, as the current flow is essentially in one dimension, along z. This insight is key to bridging the single-stage and device-level simulations.

From Section 33.2.3, we can obtain the heat generation rate Q inside the active core by running the single-stage EMC simulation. Each single-stage EMC is carried out at a specific electric field F and

FIGURE 33.9 Flowchart of the device-level thermal simulation. We start by assuming a certain current density J and temperature profile T_i across the whole device. Based on the tabulated information from the single-stage simulation and assumed (J, T_i), we get stage-by-stage profiles for the electric field F_i and the heat generation rate Q_i. An accurate temperature-dependent thermal conductivity model, which includes the boundary resistances of layers, and the temperature profile guess are used as input to the heat diffusion equation, which is then iteratively solved (with updated temperature profile in each step) until the thermal boundary conditions are satisfied.

temperature T and outputs both the current density $J(F, T)$ and the heat generation rate $Q(F, T)$. By sweeping F and T in range of interest, we obtain a table connecting different field and temperature (F, T) to appropriate current density and heat generation rate (J, Q) $[(F, T) \rightarrow (J, Q)]$. However, based on the discussion above, the input in the thermal simulation needs to be the constant parameter J. Therefore, we "flip" the recorded $(F, T) \rightarrow (J, Q)$ table to a so-called device table $(J, T) \rightarrow (Q, F)$, suitable for coupled simulation [49].

Figure 33.9 depicts the flowchart of the device-level electrothermal simulation [49]. Before the simulation, we obtain the device table $[(J, T) \rightarrow (Q, F)]$, as discussed above. We also have to calculate the thermal conductivities ($\kappa_{\|}$ and $\kappa_{\perp}$) of the active region as a function of temperature and tabulate them, based on the model described in Section 33.3.1. We also need the bulk thermal conductivity of other materials in the device (cladding layer, substrate, insulation, contact, and solder) as a function of temperature. These material properties are standard and already well characterized.

Each device-level thermal simulation is carried out in a certain environment (i.e., for a given set of boundary conditions) and with a certain current density J. At the beginning of the simulation, an initial temperature profile is assigned. With the input from the device table and the thermal conductivity data in each region, we use a finite element method to iteratively solve the heat diffusion equation until convergence. At the end of the simulation, we obtain a thermal map of the whole device. Further, from the temperature T_i in each stage and the injected current density J, we obtain the nonuniform electric field distribution F_i. With the electric field in each stage and given the stage thickness, we can accurately calculate the voltage drop across the device and obtain the current–voltage characteristic. By changing the mounting configuration (W_{act}, D_{sub}, D_{ins}, D_{cont}, D_{sold}) or the boundary conditions, the temperature profile can be changed.

33.4 Device-Level Electrothermal Simulation: An Example

In this section, we present detailed simulation results of a 9-μm GaAs/$\text{Al}_{0.45}\text{Ga}_{0.55}\text{As}$ mid-IR QCL [79] based on a conventional three-well active region design. The chosen structure has 36 repetitions of the single stage; each stage has 16 layers. Starting from the injection barrier, the layer thicknesses in one stage (in Å) are $\mathbf{46}/19/\mathbf{11}/54/\mathbf{11}/48/\mathbf{28}/34/\mathbf{17}/30/\underline{\mathbf{18}}/\underline{28}/\underline{\mathbf{20}}/\underline{30}/\mathbf{26}/30$. Here, the barriers ($\text{Al}_{0.45}\text{Ga}_{0.55}\text{As}$) are in bold while the wells (GaAs) are in normal font; the underlined layers are doped to a sheet density of $n_{\text{Si}} = 3.8 \times 10^{11}\ \text{cm}^{-2}$. The results at 77 K are shown here.

33.4.1 Electronic Simulation Results

33.4.1.1 Band Structure

Figure 33.10 shows the electronic states of the chosen structure under the designed operating field of 48 kV/cm, calculated from the coupled **k**·**p**–Poisson solver (see Section 33.2.3.1). The active region states of the central stage are represented by dark solid curves 1, 2, and 3 are the ground state and the lower

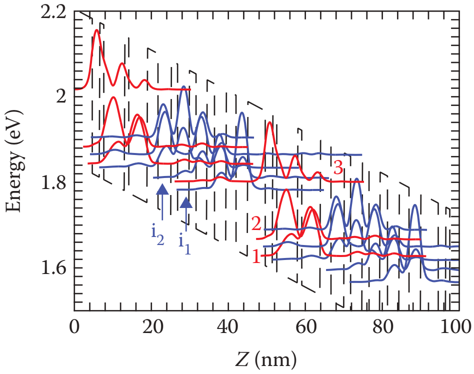

FIGURE 33.10 Energy levels and wavefunction moduli squared of Γ-valley subbands in two adjacent stages of the simulated GaAs/AlGaAs-based structure. The dark solid curves denote the active region states (1, 2, and 3 represent the ground state and the lower and upper lasing levels, respectively). The lighter solid curves represent injector states, with i_1 and i_2 denoting the lowest two. (From Y. B. Shi and I. Knezevic, *Journal of Applied Physics*, 116, 123105, 2014. With the permission of AIP Publishing.)

and upper lasing levels, respectively. Injector states are labeled i_1 and i_2. Other lightly colored solid curves denote the states that form the miniband. (When the electron density in the QCL is high, the electronic bands have to be calculated self-consistently with EMC.)

33.4.1.2 *J*-*F* Curve

The current density J versus field F curve, one of the key QCL characteristics at a given temperature, is intuitive to obtain in EMC. After calculating the electronic band structure at a certain field F, the wavefunctions, energy levels, and effective masses of each subband and each stage are fed into the EMC solver. In the EMC simulation, we include all the scattering mechanisms described in Section 33.2.3. Since we employ PBCs, the current density J can be extracted from how many electrons cross the stage boundaries in a certain amount of time in the steady state. The net flow n_{net} of electrons is calculated by subtracting the flow between the central stage and the previous stage (n_{backward}) from the flow between the central stage and the next stage (n_{forward}) in each time step. The current density is then calculated as follows:

$$J = \frac{e n_{\text{net}}}{A_{\text{eff}} \delta t} = \frac{e(n_{\text{forward}} - n_{\text{backward}})}{A_{\text{eff}} \delta t}, \tag{33.7}$$

where δt is the time interval during which the flow is recorded. A_{eff} is the effective in-plane area of the simulated device. Since doping is the main source of electrons, the area is calculated as follows:

$$A_{\text{eff}} = \frac{N_{\text{ele}}}{N_{\text{s}}}, \tag{33.8}$$

where N_{ele} is the number of simulated electrons and N_{s} is the sheet doping density (in cm^{-2}) in the fabricated device. In the current simulation, $N_{\text{ele}} = 50,000$ and $N_{\text{s}} = 3.8 \times 10^{11}\ \text{cm}^{-2}$.

Because of the stochastic nature of EMC, we need to average the current density over multiple time steps. In practice, one can record the net cumulative number of electrons per unit area that leave a stage over time and obtain a linear fit to this quantity in the steady state; the slope yields the steady-state current density.

From each individual simulation, we extract the current density at a given electric field and temperature. To obtain the *J*-*F* curve at that temperature, we sweep the electric field. To demonstrate the importance of including nonequilibrium phonons effects, we carry out the simulation with thermal phonons alone and with both thermal and excess nonequilibrium phonons. Figure 33.11 is the *J*-*F* curve for the simulated structure with (filled squares) and without (empty squares) nonequilibrium phonons at 77 K. It can be seen that the current density at a given field considerably increases when nonequilibrium phonons are included and the trend holds up to 60 kV/cm. This difference is prominent at low temperatures (<200 K) and goes away at RT [26].

33.4.1.3 Modal Gain (G_{m}) and Threshold

We calculate the modal gain as follows [22]:

$$G_{\text{m}} = \frac{4\pi e^2 \langle z_{32} \rangle^2 \Gamma_{\text{w}} \Delta n}{2\varepsilon_0 \underline{n} \gamma_{32} L_p \lambda}, \tag{33.9}$$

where ε_0 is the permittivity of free space. Some constants are obtained from experiment: waveguide confinement factor $\Gamma_{\text{w}} = 0.31$, stage length $L_p = 45$ nm, optical-mode refractive index $\underline{n} = 3.21$, and full width at half maximum $\gamma_{32}(T_{\text{L}}) \approx 8.68\ \text{meV} + 0.045\ \text{meV/K} \times T_{\text{L}}$ [26,79]. The dipole matrix element between the upper and lower lasing levels ($\langle z_{32} \rangle = 1.7$ nm) and the emission wavelength ($\lambda = 9\ \mu\text{m}$) are

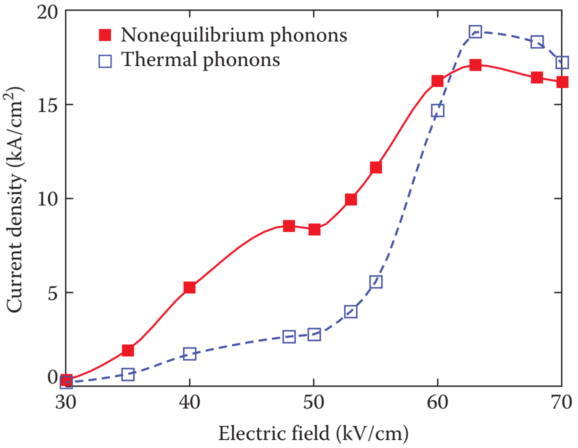

FIGURE 33.11 The current density versus electric field ($J - F$) curve of the simulated device with (filled squares) and without (empty squares) the nonequilibrium phonon effect at 77 K. The inclusion of nonequilibrium phonons considerably increases the current density at a given field up to 60 kV/cm.

also estimated in experiment [79], but we calculate these two terms directly. The dipole matrix element is calculated as follows:

$$\langle z_{32} \rangle = \int_0^d z\varphi_3^*(z)\varphi_2(z)dz\,. \tag{33.10}$$

The value is slightly different at different fields, as the band structure changes. At 48 kV/cm, the calculated matrix element is $\langle z_{32} \rangle = 1.997$ nm. Similarly, the wavelength of emitted photon also changes at different fields. One can calculate the value from the energy difference between the upper and lower lasing levels. The calculated wavelength at 48 kV/cm is 8.964 μm. $\Delta n = n_{\text{upper}} - n_{\text{lower}}$ is the population inversion obtained from EMC. Again, due to the randomness of EMC, the population inversion needs to be averaged over a period after the steady state has been reached.

Figure 33.12 shows the modal gain of the device with nonequilibrium (filled squares) and thermal (empty squares) phonons as a function of (1) electric field and (2) current density at 77 K. Horizontal dotted line indicates the total estimated loss in the device, which is used to help find the threshold current density, J_{th}. Lasing threshold is achieved when the modal gain G_{m} equals the total loss α_{tot}. We consider two sources of loss, mirror (α_{m}) and waveguide (α_{w}), so the total loss is $\alpha_{\text{tot}} = \alpha_{\text{m}} + \alpha_{\text{w}}$. The intercepts between the total loss line and the G_{m} versus F (Figure 33.12a) and G_{m} versus J (Figure 33.12b) curves give the threshold field F_{th} and threshold current density J_{th}, respectively. Like the current density, the modal gain of the device is also considerably higher when nonequilibrium phonons are considered, which leads to a lower F_{th} and a lower J_{th}. The reason for the increased current density and modal gain with nonequilibrium phonons can be attributed to the enhanced injection selectivity and efficiency [26].

33.4.1.4 Heat Generation Rate

The way to obtain the heat generation rate Q is similar to how we get the current density J. We record the cumulative net energy emission as a function of time and fit a straight line to the region where the simulation has reached a steady state. The slope of the line is used in place of $\sum(\hbar\omega_{\text{ems}} - \hbar\omega_{\text{abs}})/t_{\text{sim}}$. Figure 33.13 shows the heat generation rate as a function of electric field at 77 K. The filled squares and the empty squares depict the situation with and without nonequilibrium phonons, respectively.

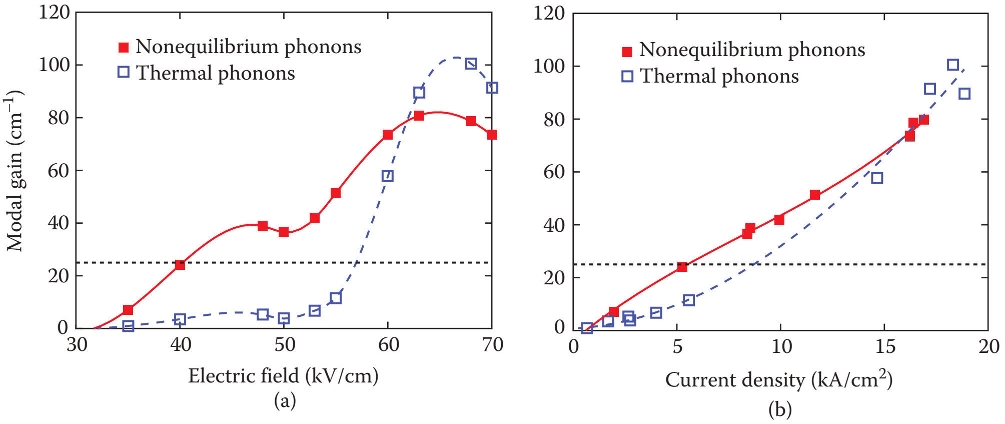

FIGURE 33.12 The modal gain (G_m) of the simulated device with nonequilibrium (filled squares) and thermal (empty squares) phonons as a function of (a) applied electric field and (b) current density *J* at 77 K. Horizontal dotted line shows the total estimated loss of the device.

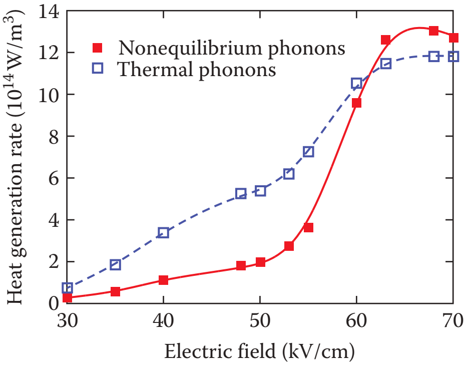

FIGURE 33.13 The heat generation rate of the simulated device as a function of electric field *F* at 77 K with (filled squares) and without (empty squares) nonequilibrium phonons.

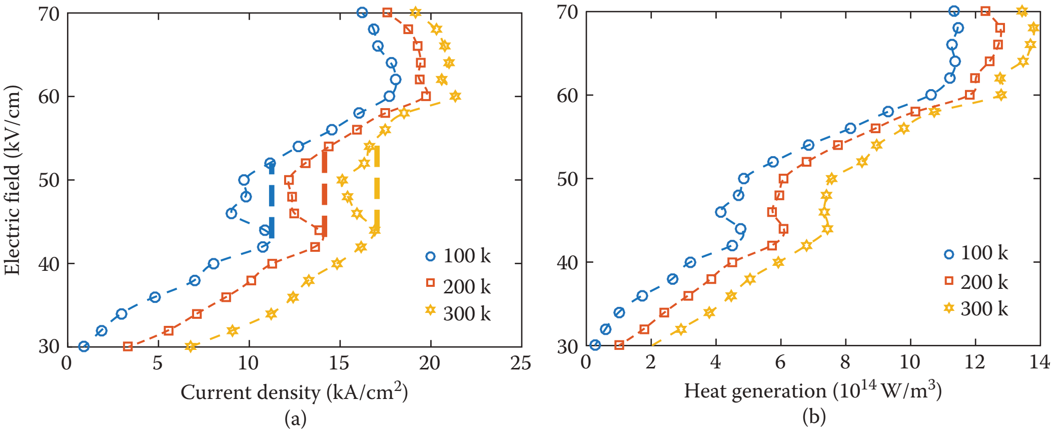
33.4.2 Representative Electrothermal Simulation Results

This section serves to illustrate how the described simulation is implemented in practice and what type of information it provides at the single-stage and device levels.

First, the single-stage-coupled simulation has to be performed at different temperatures, as in Figure 33.14a. We noted the calculated *J*-*F* curves show a negative differential conductance region, which is typical for calculations, but generally not observed in experiment. Instead, a flat *J*-*F* dependence is typically recorded [30]. At every temperature and field, we also record the heat generation rate, as depicted in Figure 33.14b.

Second, the thermal model for the whole structure is developed. Considering that growth techniques improve over time, structures grown around the same time period should have similar properties. Since the device studied here was built in 2001 [79], we assume the active core should have similar effective rms roughness Δ to other lattice-matched GaAs/AlAs SLs built around the same time [69,70]. From our



(a)

(b)

FIGURE 33.14 The field versus current density (a) and heat generation rate versus current density (b) characteristics for the simulated device at 100, 200, and 300 K, as obtained from single-stage simulation with nonequilibrium phonons.

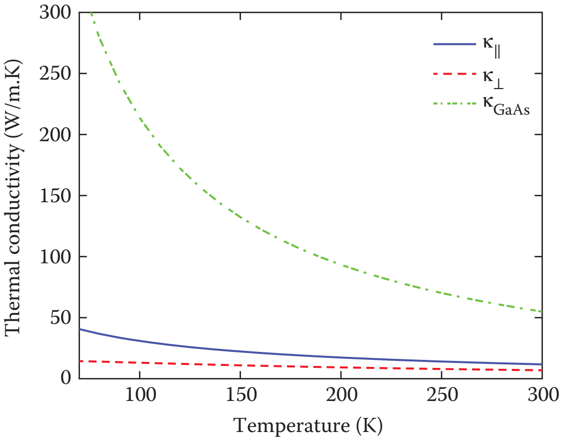


FIGURE 33.15 Calculated in-plane ($\kappa_{\|}$; solid line) and cross-plane ($\kappa_{\perp}$; dashed line) thermal conductivities of the active core along with the bulk thermal conductivity of the GaAs substrate (dash-dotted line). The effective rms roughness Δ is taken to be 5 Å.

previous simulation work on fitting the SL thermal conductivities [48], we choose an effective rms roughness $\Delta = 5$ Å in this calculation. Figure 33.15 shows the calculated thermal conductivities $\kappa_{\|}$ (solid line) and $\kappa_{\perp}$ (dashed line) along with the calculated bulk thermal conductivity (dash-dotted line) for the substrate GaAs.

The structure we considered operated in pulsed mode at 77 K. Depending on the duty cycle, the temperature distribution in the device can differ considerably. Figure 33.16 depicts a typical temperature profile across the device, while Figure 33.17 depicts the profile across the active core alone at duty cycles of 100% (essentially CW lasing, if the device achieved it) and 0.01% (as in experiment [79]). Clearly, CW operation would result in dramatic heating of the active region. Finally, Figure 33.18 shows the J–V curve of the entire simulated device at 77 K with duty cycles of 0.01%, 100%, and as observed in experiment [79].

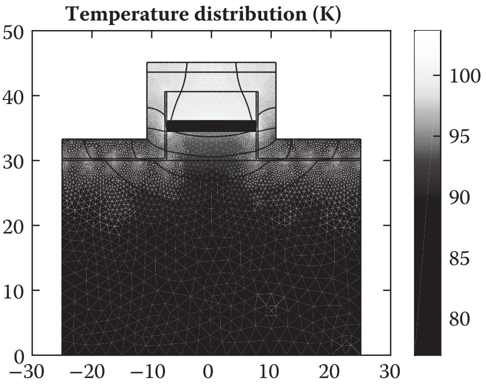

FIGURE 33.16 A typical temperature profile across the structure. At the bottom of the device is a heat sink held at 77 K, while adiabatic boundary conditions are applied elsewhere. The current density is 6 kA/cm^2 and the duty cycle is 100%.

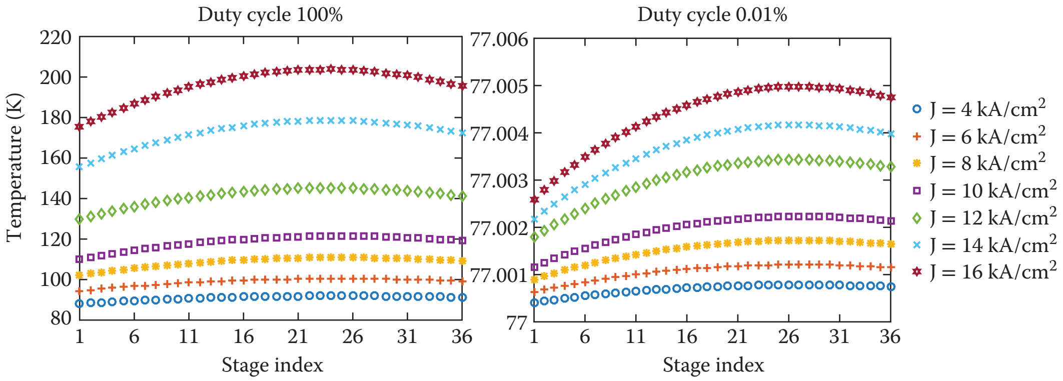

FIGURE 33.17 Temperature profile inside the active region at 100% duty cycle (left) and 0.01% duty cycle (right) for the QCL from [79].

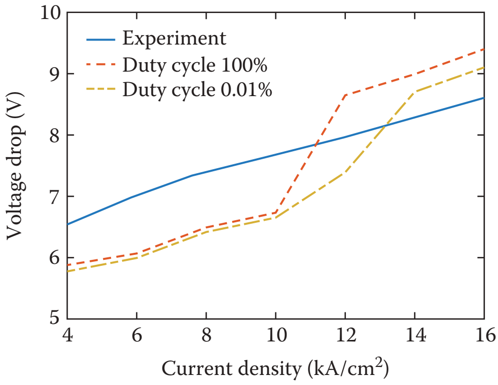

FIGURE 33.18 The current density versus voltage drop for the simulated device in experiment (solid curve) and as calculated at 100% (dashed curve) and 0.01% (dot-dashed curve) duty cycles. The bottom of the device is placed on a heat sink held at 77 K while adiabatic boundary conditions are assumed on the rest of the boundaries (see Section 33.3.2).

33.5 Conclusion

We overviewed electronic and thermal transport simulation of QCLs, as well as recent efforts in device-level electrothermal modeling of these structures, which is appropriate for transport below threshold, where the effects of the optical field are negligible. We specifically focused on mid-IR QCLs in which electronic transport is largely incoherent and can be captured by the EMC technique. The future of QCL modeling, especially for near-RT CW operation, will likely include improvements on several fronts: (1) further development of computationally efficient yet rigorous quantum transport techniques for electronic transport to fully account for coherent transport features that are important in short-wavelength mid-IR devices; (2) a better understanding and better numerical models for describing the role of electron–electron interaction, impurities, and interface roughness on device characteristics; and (3) holistic modeling approaches in which electrons, phonons, and photons are simultaneously and self-consistently captured within a single simulation. The goal of QCL simulation should be nothing less than excellent predictive value of device operation across a range of temperatures and biasing conditions, along with unprecedented insight into the fine details of exciting nonequilibrium physics that underscores the operation of these devices.

34.1 Introduction

The history of vertical-cavity surface-emitting lasers (VCSELs) can be traced back almost as far as that of semiconductor lasers themselves. In 1965, Melngailis demonstrated coherent emission parallel to the direction of the current in an $n^{+}pp^{+}$ InSb diode laser.[1] The polished surface on the emission side of InSb and the gold current contact on its opposite side provided sufficient optical feedback to enhance laser emission. In this very early work, a design was proposed for the integration in an array that would provide coherent emission over a large area, with a small beam angle. Unfortunately, this idea was forgotten and not rediscovered until 1979 by Soda et al.,[2] who demonstrated a surface-emitting InP-based diode laser with two metallic mirrors. Further development was initiated by Ogura et al.,[3] who introduced highly reflective distributed Bragg reflectors (DBRs) in 1983.

Unlike typical edge-emitting lasers, in VCSELs the optical cavity is formed between the mirrors above and below the active region (Figure 34.1). The laser light resonates in the vertical direction. Inside the laser structure, the light passes the active region in the vertical direction—i.e., gain is provided over a short distance only and the amplification per photon round-trip is small. Therefore, the mirrors must be highly reflective (over 99% for the emitting mirror and almost 100% for the opposite one) so that the photons make many round-trips before they are emitted. High reflectivity is provided by DBRs composed of stacks of two alternating layers with high refractive index contrast. With quarter-wavelength layer thicknesses, the reflected waves from all DBR interfaces add up constructively, allowing for a total DBR reflectance of over 99%. Such layers are composed of 50 or more semiconductor layers. The current is injected vertically, similar to edge-emitting devices. However, in VCSELs, optical resonance occurs in the vertical direction.

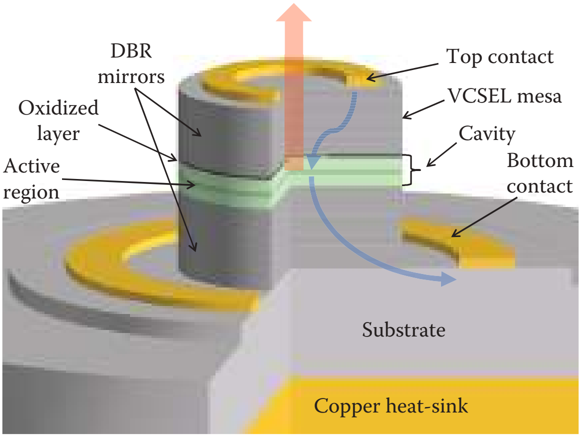

FIGURE 34.1 Intersection of a VCSEL structure showing key construction elements. The arrows inside VCSEL structure illustrate the path of the current flow and vertical arrow the emitted beam.

Optical resonance and current injection taking place in the same direction is the main weakness of these devices. Theoretically, preferential injection of the carriers to the active region may be achieved by placing two electrodes on opposite sides of the laser. However, in such configuration, the stimulated light resonates between the mirrors and no emission occurs, since the metal contacts are highly absorptive. To enable emission, a ring contact is typically used on the top DBR, through which the light is emitted. However, current flows through the shortest path, so maximal stimulated emission overlaps with the top contact, leading to high absorption in the metal and deterioration of the emission beam. To overcome this problem, the carriers must be forced to flow through the central part of the active region. This can be achieved either by selective proton implantation or by selective oxidation of the lateral regions in the VCSEL. Both of these approaches turn the semiconductor layers into electrical insulators. With selective processes, the central part of the VCSEL is conductive and radiative recombination takes place within the central part of the active region. Both methods also allow for cylindrical aperture formation, supporting cylindrical beam emission that cannot be achieved with typical edge-emitting lasers. Such symmetry of the aperture, together with the use of ring contacts, favors the choice of cylindrical geometry for numerical approaches, which are used to simulate the phenomena that take place in VCSELs during laser operation.

34.2 Physical Phenomena

VCSELs are very complex systems due to their multilayered structure (comprising in excess of a hundred layers). Often with nonplanar or buried-type architectures, they feature many heterojunctions, graded layers, quantum wells (QWs), quantum dots (QDs) or quantum wires, superlattices, oxide and oxidized layers, mesa structures, photonic microstructures, and so on. To analyze the operation of VCSELs precisely, therefore, one needs to consider four main classes of phenomena in the device: electrical, thermal, optical, and recombination, which together create a nonlinear network of mutual interrelations. Each class of phenomena is responsible for the following:

1. Optical: Cavity modes, their modal gain and loss; emission wavelengths and optical field distributions within the laser cavity; formation of the output beam
2. Electrical: Current spreading between the top and bottom contacts through the centrally located active region; injection of carriers of both polarities into the active region and their subsequent radiative or nonradiative recombination after radial out-diffusion in the active region; overbarrier carrier leakage

3. Thermal: Generation of heat flux (nonradiative recombination, reabsorption of spontaneous radiation, as well as volume and barrier Joule heating); heat spreading within heat sinks
4. Recombination: Material gain as a result of stimulated recombination (to determine the active region optical gain spectrum); nonradiative monomolecular and Auger recombinations

The main effects induced by nonlinear interaction between the models are thermal focusing and emitted power rollover. The first is related to the dependence of the refractive index on temperature. The heat induced predominantly in the central part of the active region dissipates in all directions, but mostly toward the bottom heat sink. This, in turn, induces different temperatures in the laser cavity. Increasing the temperature of semiconductor materials triggers an increase in their refractive index. The most significant increase of the refractive index is in the central part of the laser, which is heated most intensely. This causes the waveguiding effect, whereby the modes squeeze radially into the central part of the laser. On the one hand, stronger focusing of the modes in the active region increases their interaction with carriers that are injected into the central part of the active region, reducing the current necessary for laser operation (threshold current). On the other hand, if there are more optical modes confined and excited within the central part, this contributes to a broadening of the emission spectrum, since each mode relates to a slightly different emission wavelength. The quality of the output beam also deteriorates, since interference between different modes occurs at various emission angles.

The second effect—emission power rollover—limits the emitted power of the laser, mostly due to thermal effects. The active regions of VCSELs are designed in such a way that the wavelength corresponding to maximal material gain overlaps with the wavelength of the optical resonance induced by the VCSEL cavity. A change in the temperature of the device, due to heat dissipation or ambient temperature, may modify the bandgap and consequently change the wavelength corresponding to the maximum of the material gain. The optical modes do not follow the maximum of the material gain, as is the case in edge-emitting lasers, but follow the optical resonance induced by the cavity. The resonance wavelength also changes with temperature, since the refractive indices of the cavity change. The changes in maximal material gain and of cavity resonance, however, are of different proportions. Typically, the change in the gain spectrum is more sensitive to temperature changes than in the case of optical resonance. Hence, material gain can be insufficient at resonant wavelength to sustain laser operation for higher operational temperatures and the laser ceases to emit stimulated radiation. This effect is manifested as a reduction in emitted power as the injected current increases.

To simulate such complex behaviors, a comprehensive model including electrical, thermal, recombination, and optical submodels is needed. Three of these submodels can be solved in a very similar manner to the optoelectronic devices considered previously in this book. However, special attention must be given to the optical model, since electromagnetic field resonance takes place in the vertical direction, which is orthogonal to the resonance that occurs in typical edge-emitting lasers. In the remainder of this chapter, we have therefore focused on optical simulation.

34.3 Light Confinement in VCSELs

VCSELs inherently emit in single longitudinal mode due to their very short cavities. Controlling the modes in the transversal direction is more complicated. In typical VCSELs made from arsenide-based materials, well-established wet oxidation technology can be used,[4] which produces the waveguide effect through a selectively oxidized Al-rich layer that also plays the role of an electric insulator for improved current funneling to the active region. Another less material dependent technique is proton implantation,[5] which defines highly resistive regions. The waveguide effect is produced by thermal focusing induced by thermal increase of the refractive index in regions where nonradiative recombination and Joule heating occur. Other methods of transverse mode confinement require more sophisticated and expensive technologies. Possible solutions include micro-optical structures, such as surface relief,[6] antiresonant patterning,[7] tunnel junction patterning,[8] photonic crystals[9] and highcontrast gratings.[10] Each of these methods requires a separate analytical approach, since different phenomena are responsible for mode confinement: the waveguide effect, total interior reflections, Bragg reflections or Fano resonance. Since not all those phenomena can be observed in all VCSEL constructions with equal intensity, numerical models should be properly chosen to provide a balance between generalization and efficiency.

34.4 Fundamental Equations

Interaction between a VCSEL and the optical field is governed by Maxwell's equations. The boundary conditions correspond to an optical field that decays to 0 in infinity. These boundary conditions mean that Maxwell's equations turn into an eigenvalue problem. Its solutions are discrete eigenvalues and the corresponding eigenvectors. Eigenvalues of Maxwell's equations are vacuum wavevectors (k_0), corresponding angular frequencies (ω), or wavelengths in a vacuum (λ). Eigenvectors are distributions of electric (**E**) and magnetic (**H**) fields of electromagnetic waves corresponding to particular eigenvalues.

The three-dimensional electric **E** and magnetic **H** field vectors satisfy the following partial differential equations,[11] which correspond to Faraday's and Amper's laws, respectively:

$$\nabla \times \mathbf{E} = -\mu\mu_0 \frac{\partial \mathbf{H}}{\partial t}, \tag{34.1}$$

$$\nabla \times \mathbf{H} = \varepsilon\varepsilon_0 \frac{\partial \mathbf{E}}{\partial t}, \tag{34.2}$$

where μ and μ_0 are the magnetic permittivity of the material and the vacuum, respectively, and ε and ε_0 are analogous dielectric constants.

Let us consider a monochromatic wave only, of which the angular frequency is ω. The time dependency of **E** and **H** is given by the following relations:

$$\mathbf{E} = \mathbf{E} \exp(i\omega t), \tag{34.3}$$

$$\mathbf{H} = \mathbf{H} \exp(i\omega t). \tag{34.4}$$

Embedment of Equations 34.3 and 34.4 to Equations 34.1 and 34.2 results in a time-independent set of equations:

$$\nabla \times \mathbf{E} = -i\omega\mu\mu_0 \mathbf{H}, \tag{34.5}$$

$$\nabla \times \mathbf{H} = i\omega\varepsilon\varepsilon_0 \mathbf{E}. \tag{34.6}$$

We assume that μ is uniform and equal to 1, which is always true for the dielectrics and nonferromagnetic metals typically used in VCSELs. Combining Equations 34.5 and 34.6, we can reduce the set of six equations for all vector components to a set of three equations for the electric field only:

$$\nabla \times \nabla \times \mathbf{E} = k_0^2 n^2 \mathbf{E}, \tag{34.7}$$

where k_0 is the wavenumber of the mode in a vacuum and

$$\sqrt{\varepsilon} = n = n_{\mathrm{re}} + i n_{\mathrm{im}} \tag{34.8}$$

is the complex refractive index. Its imaginary part accounts for the loss and the gain of the medium in which the wave propagates. The relation between the imaginary part of n and losses α is given by

$$n_{\mathrm{im}} = -\frac{\alpha}{2\,k_0}. \tag{34.9}$$

Equation 34.9 can be rewritten in an equivalent form:

$$\nabla(\nabla\cdot\mathbf{E})-\nabla^2\mathbf{E}=\omega^2\mu\varepsilon\mathbf{E},$$
$$\nabla(\nabla\cdot\mathbf{E})-\nabla^2\mathbf{E}=k_0^2n^2\mathbf{E}. \tag{34.10}$$

VCSELs are typically processed to be circular in the epitaxial plane to support symmetric beam emission. This geometry allows the complexity of Equation 34.7 to be reduced by expressing it in a cylindrical coordinate system where the angular dependence of **E** can be given in simple analytical terms. However, in recent years, numerous confinement approaches based on photonic microstructures have been proposed. Many of these structures cannot be analyzed using the cylindrical coordinate system and therefore the three-dimensional Cartesian system must be used. We will therefore now show how Equations 34.5, 34.6, and 34.10 can be solved using three approaches of incremental complexity. The first approach is based on a one-dimensional analysis of the optical field along the optical axis. The second assumes that the VCSEL has cylindrical geometry and considers both the scalar optical field in two dimensions along the optical axis and the radius of the VCSEL. The third considers the vectorial optical field in the three-dimensional Cartesian coordinate system.

34.5 VCSEL Structure

Figure 34.2 shows the VCSEL structure with construction details listed in Table 34.1. This structure was used in References[12,13] as a benchmark for comparative analysis of optical numerical models, however it must be stressed here, the structure is significantly simplified in comparison to real-life VCSELs. The structure consists of one wavelength-long GaAs cavity with a 5-nm active GaAs layer at the antinode of the standing wave and a selectively oxidized AlAs layer ~15 nm in thickness. The cavity is sandwiched between 24 and 29.5 pairs of GaAs/AlAs DBRs. In comparison to a real-life VCSEL, there is no vertical carrier confinement that would capture and support optical recombination of the carriers. There is also no doping scheme that would allow efficient injection of the current to the active region.

In what follows, we will be using two coordinate systems: Cartesian and cylindrical (Figure 34.1). These share a z-axis along the optical axis of the device. The Cartesian plane $x-y$ and cylindrical plane $r-\varphi$ are parallel to the epitaxial layers of the VCSEL, and the x-axis relates to $\varphi=0$.

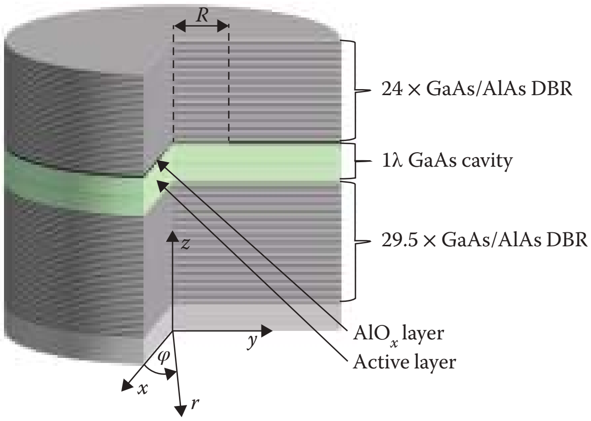

FIGURE 34.2 Intersection of the VCSEL structure with assigned radius (R) of the oxide aperture and definition of Cartesian (x, y, z) and cylindrical (r, φ, z) coordinate systems. DBR = distributed Bragg reflectors.

TABLE 34.1 Refractive Indices and Thicknesses of VCSEL Layers

Refractive Index	Thickness (nm)	Repetition
1.0	∞	–
3.53	69.49	24.5
3.08	79.63	
3.08	63.71	–
2.95 for $r < R$ 1.6 for $r > R$	15.93	–
3.53	136.49	–
3.53 (active)	5.00	–
3.53	136.49	–
3.08	79.63	29.5
3.53	69.49	
3.53	∞	–

Note: The two outer layers are assumed to be infinite.

Vectors **E** and **H** are given in the Cartesian system as

$$\mathbf{E} = \begin{bmatrix} E_x \\ E_y \\ E_z \end{bmatrix}, \quad \mathbf{H} = \begin{bmatrix} H_x \\ H_y \\ H_z \end{bmatrix}, \tag{34.11}$$

and in the cylindrical system as

$$\mathbf{E} = \begin{bmatrix} E_r \\ E_\phi \\ E_z \end{bmatrix}, \quad \mathbf{H} = \begin{bmatrix} H_r \\ H_\varphi \\ H_z \end{bmatrix}. \tag{34.12}$$

34.6 One-Dimensional Scalar Approach

The simplest approach is to consider the distribution of light within the VCSEL along the z-axis only, assuming an electromagnetic field in the form of a plane wave within the device and that the layers are uniform in the lateral direction. This extremely simplified approach allows only the longitudinal modes to be determined. However, it is of tremendous importance in VCSEL wafers designing, as it enables one to determine the size of the cavity and the number of necessary DBRs, as well as the positions of active or highly doped layers.

The assumption of uniform layers corresponds to the Gauss's law relating to electrical fields:

$$\nabla \cdot \varepsilon \mathbf{E} = 0. \tag{34.13}$$

Since ε is constant within any particular layer of the VCSEL, Gauss's law can be reduced to the following form:

$$\nabla \cdot \mathbf{E} = 0, \tag{34.14}$$

which simplifies Equation 34.10:

$$\nabla^2 \mathbf{E} = k_0^2 n^2 \mathbf{E}. \tag{34.15}$$

The operator ∇^2 can be expressed in either coordinate system. However, for the sake of clarity in what follows, we shall express it in the cylindrical system:

$$\nabla^2 \equiv \begin{bmatrix} \partial_r^2 + \frac{1}{r}\partial_r + \frac{1}{r^2}\partial_\varphi^2 + \partial_z^2 & 0 & 0 \\ 0 & \partial_r^2 + \frac{1}{r}\partial_r + \frac{1}{r^2}\partial_\varphi^2 + \partial_z^2 & 0 \\ 0 & 0 & \partial_r^2 + \frac{1}{r}\partial_r + \frac{1}{r^2}\partial_\varphi^2 + \partial_z^2 \end{bmatrix}. \tag{34.16}$$

Substituting Equation 34.16 to Equation 34.15, one obtains three independent equations for each field component of **E**:

$$\left(\partial_r^2 + \frac{1}{r}\partial_r + \frac{1}{r^2}\partial_\varphi^2 + \partial_z^2\right) E_u = k_0^2 n^2 E_u, \tag{34.17}$$

where $u = r, \varphi, z$. An additional assumption with regard to the plane wave imposes $E_r = \text{const}$ and $E_\varphi = \text{const}$, which simplifies Equation 34.17 to a one-dimensional expression:

$$\partial_z^2 E_u = k_0^2 n^2 E_u. \tag{34.18}$$

Each of the equations can be solved separately; although by imposing the assumption of layer uniformity, we lose information on the relations between the components of the electric field. Hence, it is useful to assume that when linearly polarized light propagates along the z-axis then

$$E_z = 0$$

and

$E_\varphi = E_r \cot\varphi$ for x polarization or

$E_\varphi = E_r \tan\varphi$ for y polarization.

To solve Equation 34.18, we used the transfer matrix method (TMM),[14] which assumes that within the jth layer the solution of Equation 34.18 can be expressed by the function (Figure 34.3):

$$E_r^j = A_j \exp\left(ik_j z\right) + B_j \exp\left(-ik_j z\right), \tag{34.19}$$

where $k_j = k_0 n_j$ and E_r is continuous and smooth at the interfaces between the consecutive layers of the VCSEL (Figure 34.3). This leads to the following relations:

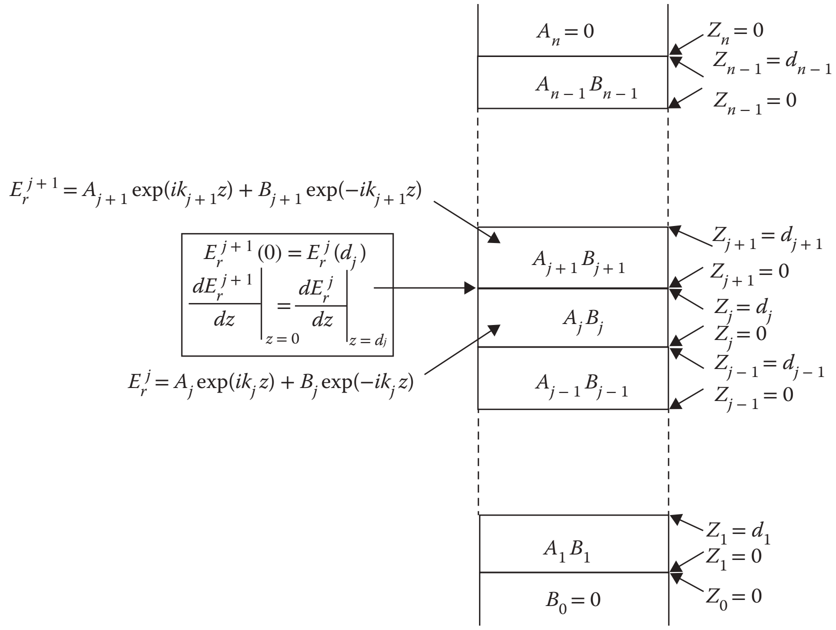
$$A_j \exp\left(ik_j d_j\right) + B_j \exp\left(-ik_j d_j\right) = A_{j+1} \exp\left(ik_{j+1} 0\right) + B_{j+1} \exp\left(-ik_{j+1} 0\right), \tag{34.20}$$

$$\frac{\mathrm{d}}{\mathrm{d}z}\left(A_j \exp\left(ik_j z\right) + B_j \exp\left(-ik_j z\right)\right)\bigg|_{z=d_j} = \frac{\mathrm{d}}{\mathrm{d}z}\left(A_{j+1} \exp\left(ik_{j+1} z\right) + B_{j+1} \exp\left(-ik_{j+1} z\right)\right)\bigg|_{z=0}, \tag{34.21}$$

at neighboring layers expressed in local coordinates within layers; k_0 is unknown and corresponds to the vacuum wavevector of the mode.

As a consequence, we can write the relation that transforms E_r between the layers as follows:

$$\begin{matrix} A_j \frac{k_{j+1}+k_j}{2k_{j+1}} \exp\left(ik_j d_j\right) + \frac{k_{j+1}-k_j}{2k_{j+1}} B_j \exp\left(-ik_j d_j\right) = A_{j+1} \\ A_j \frac{k_{j+1}-k_j}{2k_{j+1}} \exp\left(ik_j d_j\right) + \frac{k_{j+1}+k_j}{2k_{j+1}} B_j \exp\left(-ik_j d_j\right) = B_{j+1} \end{matrix}, \tag{34.22}$$



$A_n = 0$
$Z_n = 0$
$Z_{n-1} = d_{n-1}$
$A_{n-1}B_{n-1}$
$Z_{n-1} = 0$
$E_r^{j+1} = A_{j+1}\exp(ik_{j+1}z) + B_{j+1}\exp(-ik_{j+1}z)$
$E_r^{j+1}(0) = E_r^j(d_j)$
$\left.\frac{dE_r^{j+1}}{dz}\right|_{z=0} = \left.\frac{dE_r^j}{dz}\right|_{z=d_j}$
$Z_{j+1} = d_{j+1}$
$A_{j+1}B_{j+1}$
$Z_{j+1} = 0$
A_jB_j
$Z_j = d_j$
$Z_j = 0$
$Z_{j-1} = d_{j-1}$
$E_r^j = A_j\exp(ik_jz) + B_j\exp(-ik_jz)$
$A_{j-1}B_{j-1}$
$Z_{j-1} = 0$
$Z_1 = d_1$
A_1B_1
$Z_1 = 0$
$B_0 = 0$
$Z_0 = 0$

FIGURE 34.3 Schematic view of structure illustrating parameters and variables used in TMM algorithm.

and this can be given in a matrix form:

$$\begin{bmatrix} A_{j+1} \\ B_{j+1} \end{bmatrix} = \begin{bmatrix} \frac{k_{j+1}+k_j}{2k_{j+1}} \exp\left(ik_jd_j\right) & \frac{k_{j+1}-k_j}{2k_{j+1}} \exp\left(-ik_jd_j\right) \\ \frac{k_{j+1}-k_j}{2k_{j+1}} \exp\left(ik_jd_j\right) & \frac{k_{j+1}+k_j}{2k_{j+1}} \exp\left(-ik_jd_j\right) \end{bmatrix} \begin{bmatrix} A_j \\ B_j \end{bmatrix} = \mathbf{M_j} \begin{bmatrix} A_j \\ B_j \end{bmatrix}. \tag{34.23}$$

Matrix $\mathbf{M}_j$ connects the amplitudes of the electric field from layers j and $j + 1$. All layers of the VCSEL can be combined using the recursive relation:

$$\begin{bmatrix} A_n \\ B_n \end{bmatrix} = \prod_{j=0}^{n} \mathbf{M}_j \begin{bmatrix} A_0 \\ B_0 \end{bmatrix} = \mathbf{M} \begin{bmatrix} A_0 \\ B_0 \end{bmatrix}. \tag{34.24}$$

Boundary conditions impose that the electric field decays to infinity, so the exponential elements responsible for infinite values of E in $+\infty$ and $-\infty$ must be eliminated:

$$\begin{bmatrix} 0 \\ B_n \end{bmatrix} = \mathbf{M} \begin{bmatrix} A_0 \\ 0 \end{bmatrix} = \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} \begin{bmatrix} A_0 \\ 0 \end{bmatrix}. \tag{34.25}$$

This relation implies that

$$m_{11}\left(k_0\right) = 0, \tag{34.26}$$

which is the condition in the numerical algorithm responsible for finding the longitudinal modes of the VCSEL. k_0, which fulfills the condition (Equation 34.26), corresponds to the longitudinal mode of the VCSEL and is interpreted as the wavenumber of the longitudinal mode in the vacuum. Simple relations give the emitted wavelength as well as the frequency of the mode. The imaginary part of k_0 corresponds to the total losses or gain of the mode. If $\mathrm{im}(k_0) \geq 0$, the mode reaches the threshold and can be observed in the emitted spectrum.

The vertical mode distribution for the structure detailed in Table 34.1, calculated using TMM, is given in Figure 34.4. Mode intensity is defined as follows:

$$I = E_u E_u^*, \tag{34.27}$$

where E^* is a complex conjugate of the electric field of an electromagnetic wave. Figure 34.4 shows typical oscillatory decay of optical field intensity within the top and bottom DBRs. In the simplified example considered here, in which the cavity is uniform, optical intensity is maximal and the amplitude is constant in the cavity. Typically, VCSELs are designed to ensure the coincidence of optical field intensity and the active region to maximize stimulated emission.

Using this simple approach, one can design the dominant wavelength of the VCSEL wafer by tuning the length of the cavity. Figure 34.5 illustrates the dependence of the resonant wavelength and modal gain as functions of detuning the cavity length from its optimal length. The cavity length and DBR stopband were originally designed for 980 nm. Detuning the cavity length and leaving the parameters of the DBRs unchanged shift the emitted wavelength. However, modal gain remains close to its maximal value in the limited range of detuning. Greater detuning induces significant shift of the resonant wavelength, which is more weakly reflected by the DBRs, and modal gain decreases.

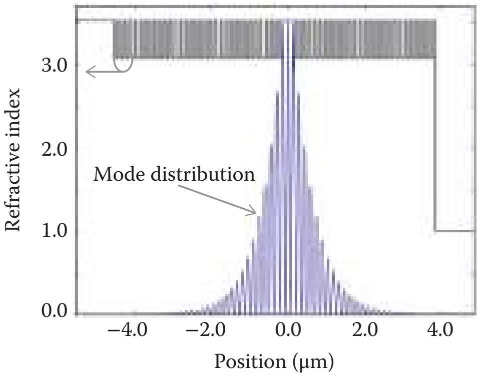


FIGURE 34.4 Distribution of the longitudinal mode and distribution of the refractive index along the optical axis of the VCSEL (Table 34.1).

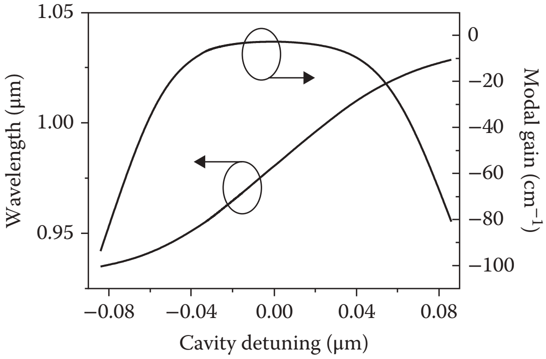

FIGURE 34.5 Modification of the resonant wavelength and modal gain induced by modification of the cavity length.

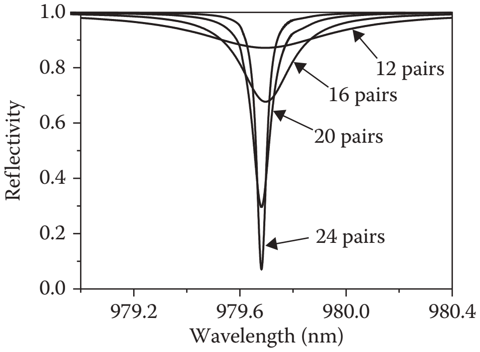

FIGURE 34.6 Power reflectance of the VCSEL wafer as a function of the incident wavelength for different numbers of DBR pairs.

Using the same method, but changing the boundary conditions to allow wave propagation toward the structure, one can calculate the reflectance or transmittance of the VCSEL wafer. In the case of a structure with an unpumped active region (in our calculations, absorption of 3000 cm^{-1} in the active region was assumed), there is a characteristic dip in the reflectance spectrum (Figure 34.6). If the dip is narrow and tends toward 0 reflectance, this indicates that the structure provides strong resonance for incident light that is absorbed by the active region. Such calculations can be compared directly with experimental measurements taken from the reflectance spectrum of the VCSEL wafer.

34.7 Two-Dimensional Scalar Approach

A more comprehensive approach, allowing lateral mode determination but still requiring moderate usage of computational memory and time, assumes that the electric field can be expressed independently using three coordinates: r, φ, and z:

$$E_u = E_u^{\text{rad}}(r)E_u^{\text{azim}}(\varphi)E_u^{ax}(z). \tag{34.28}$$

If the geometry of the device is cylindrical, one can assume the periodic dependence of

$$E_u^{\text{azim}}(\varphi) \sim \sin(m\varphi) \text{ or } E_u^{\text{azim}}(\varphi) \sim \cos(m\varphi), \tag{34.29}$$

which in practice reduces the problem to two dimensions (r, z).

Another assumption that makes use of the one-dimensional solution of (Equation 34.18) axial dependence can be expressed as

$$E_u^{ax} = A\exp\left(ik_{ax}z\right) + B\exp\left(-ik_{ax}z\right), \tag{34.30}$$

where k_{ax} is calculated for each cylinder (Figure 34.7) separately if the lateral distributions of the refractive indices in each cylinder are uniform in the radial direction. Equation 34.17 can then be transformed into

$$\left(\partial_r^2 + \frac{1}{r}\partial_r + k_{ax}^2 - k_0^2n^2 - \frac{m^2}{r^2}\right)E_u = 0, \tag{34.31}$$

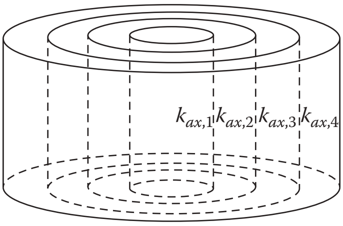

FIGURE 34.7 Schematic arrangement of cylinders. Wavenumbers $k_{ax,i}$ were calculated using one-dimensional TMM.

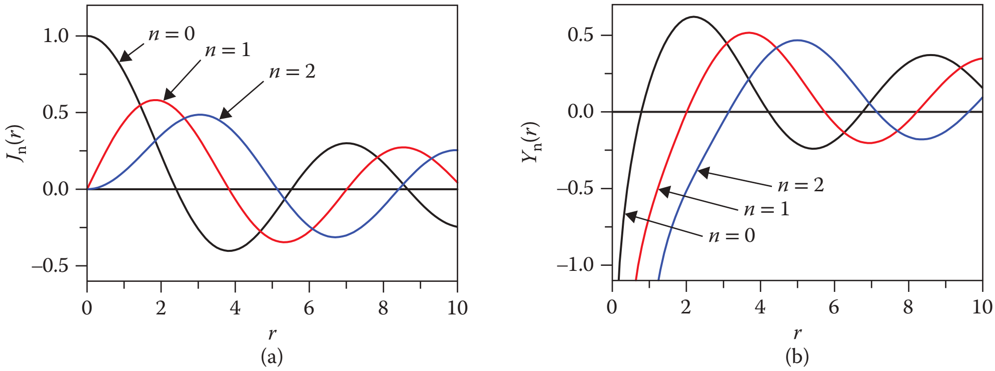

FIGURE 34.8 Bessel functions of the first (a) and second (b) kinds for $n = 0, 1, 2$.

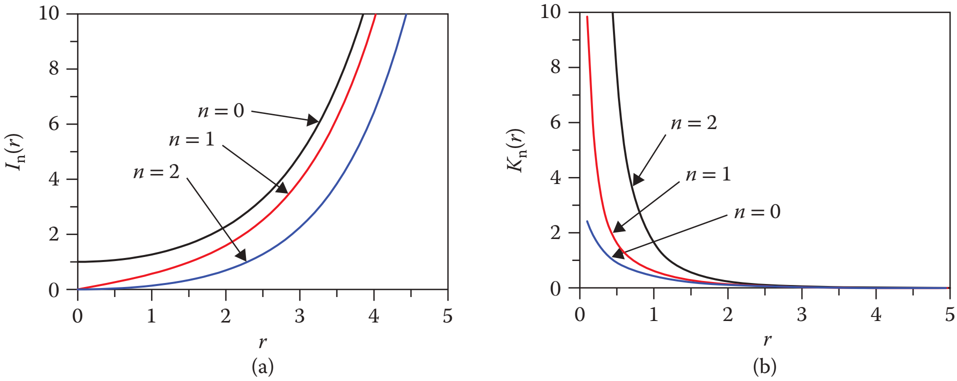

FIGURE 34.9 Modified Bessel function of the first (a) and second (b) kinds for $n = 0, 1, 2$.

which is solved separately for different m. The solutions of these Bessel differential equations are combinations of Bessel functions of the first $J_m(ar)$ and second kind $Y_m(ar)$ (Figure 34.8), where

$$a = k_{ax}^2 - k_0^2 n^2. \tag{34.32}$$

When $a < 0$, it is convenient to use modified Bessel functions of the first $I_m(-ar)$ and second kind $K_m(-ar)$ (Figure 34.9).

The following sums give the solution for an arbitrary layer:

$$E_{u,j}^{\mathrm{rad}} = A_j J_m\left(a_j r\right) + B_j Y_m\left(a_j r\right) \tag{34.33}$$

or

$$E_{u,j}^{\mathrm{rad}} = A_j I_m\left(-a_j r\right) + B_j K_m\left(-a_j r\right). \tag{34.34}$$

Implementing conditions for continuity of E_u^{rad} and continuity of their derivatives at the interfaces between cylinders, one can construct a transfer matrix between the electric fields in separate cylinders. In a similar manner as in Equation 34.24, one can construct a relation combining the fields from the first and last cylinders. The boundary conditions correspond to a finite value for the field at the center of the structure and to a decaying field for $r \to \infty$. The first condition eliminates $Y_m(ar)$ from the solution in the first cylinder and $I_m(-ar)$ in the last, which implies a condition similar to Equation 34.26. The set of k_0's that fulfill this condition correspond to lateral modes. Algorithms based on these approaches are very efficient and can be performed on personal computers.

The intensities of the lateral modes and the corresponding emission wavelengths of the VCSEL (Table 34.2), calculated using the algorithm detailed in this chapter, are presented in Figure 34.10. The set of modes illustrated were calculated assuming $E_u^{\mathrm{azim}}(\varphi) \sim \cos(m\varphi)$. A corresponding set can be calculated for $E_u^{\mathrm{azim}}(\varphi) \sim \sin(m\varphi)$, for which the emitted wavelengths will be exactly the same as for $\sim \cos(m\varphi)$. Superposition of these solutions and their complex conjugation leads to the elimination of angular dependence and only the oval shapes of the modes can be observed. However, in real-life structures in which perfect cylindrical symmetry can be broken by the geometry of the optical aperture or by the crystallographic structure of the layers, separate modes corresponding to both solutions can be observed.

34.8 Three-Dimensional Vectorial Approach

The three-dimensional vectorial approach relies on relations (Equations 34.5 and 34.6). To consider these in general geometries, we use the Cartesian coordinate system and assume that the medium in which field propagates is nonisotropic. The curl operator ∇× in the Cartesian coordinate system is defined as follows:

$$\nabla\times \equiv \begin{bmatrix} 0 & -\partial_z & \partial_y \\ \partial_z & 0 & -\partial_x \\ -\partial_y & \partial_x & 0 \end{bmatrix}. \tag{34.35}$$

We can eliminate E_z and H_z:

$$\begin{aligned} H_z &= \begin{bmatrix} -\frac{i}{\omega\mu_z\mu_0}\partial_y & \frac{i}{\omega\mu_z\mu_0}\partial_x \end{bmatrix}\begin{bmatrix} E_x \\ E_y \end{bmatrix} \\ E_z &= \begin{bmatrix} -\frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_x & \frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_y \end{bmatrix}\begin{bmatrix} H_y \\ H_x \end{bmatrix}, \end{aligned} \tag{34.36}$$

which leads to the relations:

$$\begin{aligned} \partial_z\bar{\mathbf{E}} &= \begin{bmatrix} -\partial_x\frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_x - \omega\mu_y\mu_0 & \partial_x\frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_y \\ -\partial_y\frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_x & \partial_y\frac{i}{\omega\varepsilon_z\varepsilon_0}\partial_y - \omega\mu_x\mu_0 \end{bmatrix}\bar{\mathbf{H}} = \mathbf{R_E}\bar{\mathbf{H}} \\ \partial_z\bar{\mathbf{H}} &= \begin{bmatrix} -\partial_y\frac{i}{\omega\mu_z\mu_0}\partial_y - \omega\varepsilon_x\varepsilon_0 & \partial_y\frac{i}{\omega\mu_z\mu_0}\partial_x \\ -\partial_x\frac{i}{\omega\mu_z\mu_0}\partial_y & \partial_x\frac{i}{\omega\mu_z\mu_0}\partial_x - \omega\varepsilon_y\varepsilon_0 \end{bmatrix}\bar{\mathbf{E}} = \mathbf{R_H}\bar{\mathbf{E}} \end{aligned}, \tag{34.37}$$

where

$$\bar{\mathbf{H}} = \begin{bmatrix} H_x \\ H_y \end{bmatrix} \text{ and } \bar{\mathbf{E}} = \begin{bmatrix} E_x \\ E_y \end{bmatrix}. \tag{34.38}$$

Equations 34.37 can be transformed into

$$\begin{aligned} \partial_z^2\bar{\mathbf{E}} &= \mathbf{R_H}\mathbf{R_E}\bar{\mathbf{E}} \\ \partial_z^2\bar{\mathbf{H}} &= \mathbf{R_E}\mathbf{R_H}\bar{\mathbf{H}} \end{aligned}. \tag{34.39}$$

Both equations can be solved in the base, which simplifies the matrices $\mathbf{R_H R_E}$ and $\mathbf{R_E R_H}$ into diagonal forms. The following analysis leads to the solution of Equation 34.39 and enables the characteristic value of the problem to be found. The solution corresponds to the wavenumber of the mode, as well as to the characteristic vectors, which determine the distribution of the electromagnetic field within the structure.

The equation for the electric field rewritten in the new virtual base (after diagonalization) is

$$\partial_z^2 \hat{\mathbf{E}} = \mathbf{R_H R_E} \hat{\mathbf{E}}, \tag{34.40}$$

where $\hat{\mathbf{E}}$ stand for electric field in the new, virtual base and can be defined as

$$\hat{\mathbf{E}} = \mathbf{T}_\mathbf{E}^{-1} \bar{\mathbf{E}}, \tag{34.41}$$

where the matrix $\mathbf{T_E}$ diagonalizes $\mathbf{R_H R_E}$:

$$\mathbf{T}_\mathbf{E}^{-1} \mathbf{R_H R_E T_E} = \boldsymbol{\Gamma}_\mathbf{E}^2. \tag{34.42}$$

Here $\boldsymbol{\Gamma}_\mathbf{E}^2$ is a diagonal matrix, which allows a solution of Equation 34.39 in the well-known form of a standing wave:

$$\hat{\mathbf{E}}(z) = \mathbf{A} \cosh\left(i\boldsymbol{\Gamma}_\mathbf{E} z\right) + \mathbf{B} \sinh\left(i\boldsymbol{\Gamma}_\mathbf{E} z\right). \tag{34.43}$$

For further derivation, we can use values of the electric field equal to $\hat{\mathbf{E}}_0$ and $\hat{\mathbf{E}}_d$ on the extreme borders of the uniform region along the z direction. The thickness of the considered uniform layer equals d (Figure 34.10).

We can therefore relate the solution to the values of the field at the opposite borders of the uniform region:

$$\hat{\mathbf{E}}(z) = \hat{\mathbf{E}}_\mathbf{0} \cosh\left(i\boldsymbol{\Gamma}_\mathbf{E} z\right) + \left(\hat{\mathbf{E}}_\mathbf{j} \sinh^{-1}\left(i\boldsymbol{\Gamma}_\mathbf{E} d\right) - \hat{\mathbf{E}}_\mathbf{0} \tanh^{-1}\left(i\boldsymbol{\Gamma}_\mathbf{E} d\right)\right) \sinh\left(i\boldsymbol{\Gamma}_\mathbf{E} z\right). \tag{34.44}$$

The solution for the magnetic field can be found in a similar manner.

Using the solution for $\hat{\mathbf{E}}$ and $\hat{\mathbf{H}}$ and substituting to Equation 34.37, one can find the relation connecting electric and magnetic fields within the layer:

$$\begin{bmatrix} \hat{\mathbf{H}}_0 \\ -\hat{\mathbf{H}}_d \end{bmatrix} = \begin{bmatrix} \mathbf{y}_1 & \mathbf{y}_2 \\ \mathbf{y}_2 & \mathbf{y}_1 \end{bmatrix} \begin{bmatrix} \hat{\mathbf{E}}_0 \\ \hat{\mathbf{E}}_d \end{bmatrix}, \tag{34.45}$$

where

$$\mathbf{y}_1 = \left(\mathbf{T}_\mathbf{E}^{-1} \mathbf{R_H T_H}\right)^{-1} \boldsymbol{\Gamma}_\mathbf{E} \tanh^{-1}\left(i\boldsymbol{\Gamma}_\mathbf{E} d\right), \tag{34.46}$$

$$\mathbf{y}_2 = -\left(\mathbf{T}_\mathbf{E}^{-1} \mathbf{R_H T_H}\right)^{-1} \boldsymbol{\Gamma}_\mathbf{E} \sinh^{-1}\left(i\boldsymbol{\Gamma}_\mathbf{E} d\right). \tag{34.47}$$

The relation between the fields from the ith and $(i-1)$th layers is given in the formulas:

$$\hat{\mathbf{E}}_0^{(i)} = \left(\mathbf{T}_\mathbf{E}^{(i)}\right)^{-1} \mathbf{T}_\mathbf{E}^{(i-1)} \hat{\mathbf{E}}_d^{(i-1)} = \mathbf{t}_\mathbf{E}^{(i)} \hat{\mathbf{E}}_d^{(i-1)}, \tag{34.48}$$

$$\hat{\mathbf{H}}_0^{(i)} = \left(\mathbf{T}_\mathbf{H}^{(i)}\right)^{-1} \mathbf{T}_\mathbf{H}^{(i-1)} \hat{\mathbf{H}}_d^{(i-1)} = \mathbf{t}_\mathbf{H}^{(i)} \hat{\mathbf{H}}_d^{(i-1)}. \tag{34.49}$$

Using Equations 34.45, 34.48, and 34.49, the relationship between the electric and magnetic fields, for the interface separating layers $i+1$ and i, takes an iterative formula:

$$\hat{\mathbf{H}}_d^{(i)} = \mathbf{Y}^{(i)}\hat{\mathbf{E}}_d^{(i)}, \tag{34.50}$$

$$\mathbf{Y}^{(i)} = -\left(\mathbf{y}_2^{(i)}\left(\mathbf{t}_{\mathbf{H}}^{(i)}\mathbf{Y}^{(i-1)}\left(\mathbf{t}_{\mathbf{E}}^{(i)}\right)^{-1} - \mathbf{y}_1^{(i)}\right)^{-1}\mathbf{y}_2^{(i)} + \mathbf{y}_1^{(i)}\right). \tag{34.51}$$

Propagating by this procedure from the bottom limit of the simulated structure to the upper limit, the characteristic equation can be determined. However, from the numerical point of view, it is more efficient and precise to perform the procedure starting from the bottom limit to the center, and then to start again from the upper limit down to the center. The center does not correspond to the geometrical center but to the plane at which the electromagnetic field reaches or it is close to its maximum, which is termed as the "matching interface." One can write the relation (Equation 34.50) for the top-down and bottom-up algorithms as:

$$\hat{\mathbf{H}}_d^{(m)} = \mathbf{Y}_{\mathrm{up}}^{(m)}\hat{\mathbf{E}}_d^{(m)}, \tag{34.52}$$

$$\hat{\mathbf{H}}_d^{(l)} = \mathbf{Y}_{\mathrm{down}}^{(l)}\hat{\mathbf{E}}_d^{(l)}. \tag{34.53}$$

m counts layers from the bottom and l from the top.

Since the magnetic field is continuous in the matching interface in the real base, one can write the relation

$$\bar{\mathbf{H}}_d^{(m)} = \bar{\mathbf{H}}_d^{(l)}. \tag{34.54}$$

Transforming back Equation 34.54 to the virtual base:

$$\mathbf{T}_{\mathbf{H}}^{(m)}\hat{\mathbf{H}}_d^{(m)} = \mathbf{T}_{\mathbf{H}}^{(m)}\hat{\mathbf{H}}_d^{(l)}, \tag{34.55}$$

using Equations 34.52 and 34.53:

$$\mathbf{T}_{\mathbf{H}}^{(m)}\mathbf{Y}_{\mathrm{up}}^{(m)}\hat{\mathbf{E}}_d^{(m)} = \mathbf{T}_{\mathbf{H}}^{(m)}\mathbf{Y}_{\mathrm{down}}^{(l)}\hat{\mathbf{E}}_d^{(l)}, \tag{34.56}$$

and finally using relation (Equation 34.41) to lead us to an equation that includes the fields in the real base:

$$\left(\mathbf{T}_{\mathbf{H}}^{(m)}\mathbf{Y}_{\mathrm{up}}^{(m)}\left(\mathbf{T}_{\mathbf{E}}^{(m)}\right)^{-1} - \mathbf{T}_{\mathbf{H}}^{(m)}\mathbf{Y}_{\mathrm{down}}^{(l)}\left(\mathbf{T}_{\mathbf{E}}^{(l)}\right)^{-1}\right)\bar{\mathbf{E}} = \mathbf{Y}\bar{\mathbf{E}} = 0. \tag{34.57}$$

Equation 34.57 is also the characteristic value equation. The solution of the equation determines the characteristic values, which correspond to the complex wavenumber. As before, the imaginary part of the characteristic value relates to the modal gain of the propagating wave. Equation 34.57 has a nontrivial solution only if matrix **Y** is singular, which imposes the condition that one of the eigenvalues of **Y** is 0. This condition is useful in numerical searches for solutions to Equation 34.57.

The intensity distributions of lateral modes calculated using the vectorial approach are very close to those depicted in Figure 34.11. The main difference between the solutions lies in the different number of modes (Table 34.3). In the vectorial solution, there are no modes of shorter wavelengths than LP_{22}. This may be associated with diffraction losses, which are more severe for higher order modes but are not included in the scalar model.

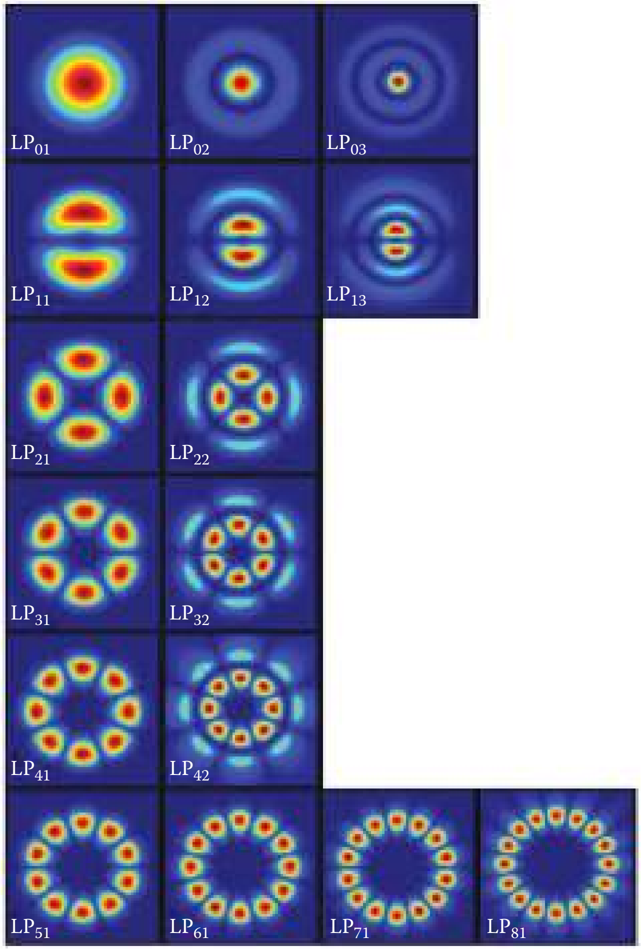

FIGURE 34.11 Distributions of lateral modes in the VCSEL structure detailed in Table 34.1, where $R = 4$ μm, calculated using the scalar two-dimensional approach.

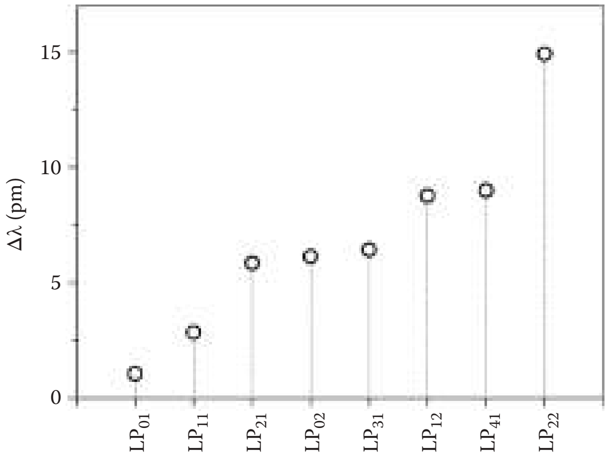

FIGURE 34.12 Difference in resonant wavelengths of successive lateral modes calculated using scalar and vectorial models.

Figure 34.12 illustrates the difference (Δλ) with respect to the wavelength of modes calculated using scalar and vectorial models. The vectorial model provides solutions with shorter wavelengths. However, the difference is on a scale of picometers. The monotonic increase in Δλ shows that the plane wave assumption used in the scalar model is more accurate in the case of lower order modes.

34.9 Impact of Oxide Aperture Diameter and Position

Finally, we shall analyze the influence of oxide aperture on the emitted wavelength of the VCSEL considered in this study. Although the structure is a very simplified design, the general tendencies presented in Figures 34.13 and 34.14 are applicable to real-life oxide-confined VCSEL structures.

Reducing the aperture (Figure 34.13) size leads to a characteristic blue shift, since a narrower aperture introduces stronger interaction between the mode and the oxide layer, which has a low refractive index. The wider the aperture diameter, the closer the values for the wavelengths determined using each approach.

The location of the oxide layer has a significant effect on the VCSEL parameters (Figure 34.14). If it is positioned at the antinode of the standing wave, the interaction between the optical field and carriers within the active region is intensified, since the modes are strongly confined within the aperture. This configuration reduces the threshold current and broadens the spectrum of emission, as numerous lateral modes are excited. If the oxide layer is in the node position, the number of modes is reduced, which narrows the

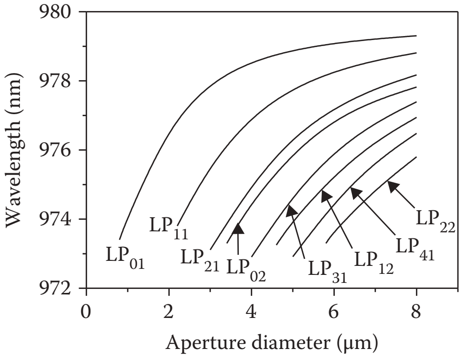

FIGURE 34.13 Dependence of the lateral mode wavelengths on aperture diameter.

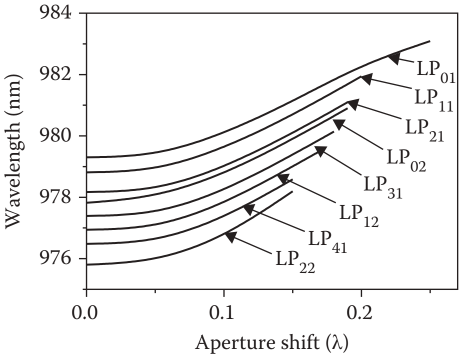

FIGURE 34.14 Dependence of lateral mode wavelengths on aperture shift from the antinode position relative to the wavelength of the standing wave.

emitted spectrum. However, interaction between the mode and the oxide layer is weaker and the threshold current increases. Shifting the oxide layer from the antinode position leads to an increase in the wavelength. This can be explained by weaker interaction between the field and the oxidized layer, which leads to an increase in the effective index of the mode and eventually causes redshift.

34.10 Conclusion

Scalar one- and two-dimensional optical approaches represent very efficient tools for VCSEL designers. Their calculation algorithms, requiring short calculation times and minor memory storage, enable one to perform rapid calculations using even PCs. However, the assumptions that make them so efficient introduce simplifications, which may produce inaccurate results in more sophisticated structures. Most significantly, the basic scalar assumption of plane optical wave propagation is violated in the case of aperture sizes comparable to the radiation wavelength and for higher order modes.

Vectorial methods are much more complicated, since they are based on the solution of six coupled equations instead of only one (in the simplified scalar approach). They give more exact results at the price of significantly longer computational time and a considerably more complicated algorithm. Vectorial methods may not be the optimal approach to modeling a standard VCSEL. However, analysis of VCSELs with in-built refractive index steps in lateral directions or subwavelength patterning certainly requires the use of vectorial methods.

35.1 Introduction

Photodetectors (PDs) convert light energy into electrical energy, which usually manifests as a photocurrent. They are a kind of transducer. The electrical signal is useful in electronic imaging, providing a means for viewing images much faster than the earlier photographic imaging. PDs also find important applications in present-day fiber-optic communication systems. In this case, PDs receive the stream of weak optical pulses at the far end of the optical fiber originally transmitted by the transmitter. The role of the detector is to convert these optical pulses into electrical pulses, which are then processed for use in a telephone, a computer, or other terminals at the receiving end (Bhattacharyya 1996; Deen and Basu 2012; Kumar and Deen 2014).

Other important applications of PDs include automatic door opener, use in remote control elements in TV, VCR, air conditioners, etc., in CCDs in a video camera, and in astronomy, research, and defense.

This chapter gives an introduction to the working principle of photodetection by semiconductors, the material properties, different types, and their structures, important parameters pertaining to PDs, and materials and makes a list of the application areas.

35.2 Basic Working Principle

The conversion of optical energy into electrical energy by a PD involves three basic processes. First, a bunch of incident photons is absorbed by the semiconducting material to create excess electron–hole pairs (EHPs). The carriers are then transported across the absorption or transit region. In the third stage, the transported carriers are collected to generate photocurrent. In this section, we consider the basic principle, structure, and the process of absorption (Bhattacharyya 1996; Deen and Basu 2012).

35.2.1 Conversion of Light into Current

The process of creation of excess EHPs and their collection is illustrated in Figure 35.1. In Figure 35.1a, a photon of energy $\hbar\omega \geq E_g$, incident on the semiconductor, is absorbed by an electron in the valence band (VB), which then moves up in the conduction band (CB), leaving a hole in the VB. An excess EHP, in excess of the thermal equilibrium values, is therefore created. To collect these carriers, a reverse-biased p-n junction is employed. As shown in Figure 35.1b, the electric field in the depletion layer drives the excess electrons and excess holes in the opposite directions to be collected by the terminals and thus to produce current. The reverse saturation current in the absence of illumination is called the dark current. The photogenerated current is proportional to the flux of incident photons or the power of incident light (Kaiser 2013; Senior and Jamro 2009).

As shown in Figure 35.1b, absorption may also take place outside the depletion layer. The excess EHPs generated therein move by the slower process of diffusion and are collected by the terminals. The diffusion process limits the speed of operation and distorts the electrical pulses.

35.2.2 Absorption in Semiconductors

The process of absorption is now discussed in some detail in Figure 35.2. In Figure 35.2a, a photon of energy $\hbar\omega \geq E_g$ is shown incident on the semiconductor. The photon lifts an electron from the VB to a higher lying state in the CB. The energetic electron then relaxes to the bottom of the CB via phonon emission. A photon thus creates an excess EHP. The pair ultimately recombines to give rise to emission (luminescence). The same processes are illustrated in the E-k diagrams of a direct gap semiconductor in Figure 35.2b and of an indirect gap semiconductor in Figure 35.2c. The photon momentum $\hbar\mathbf{k}_{\text{photon}}$ is usually negligible and the momentum ($\mathbf{k}$) conservation can be written as $\mathbf{k}_e = \mathbf{k}_h + \mathbf{k}_{\text{photon}} \approx \mathbf{k}_h$, where $\mathbf{k}_e(\mathbf{k}_h)$ denotes the wave vector for electron (hole). Accordingly, the absorption in a direct gap semiconductor is indicated by a vertical

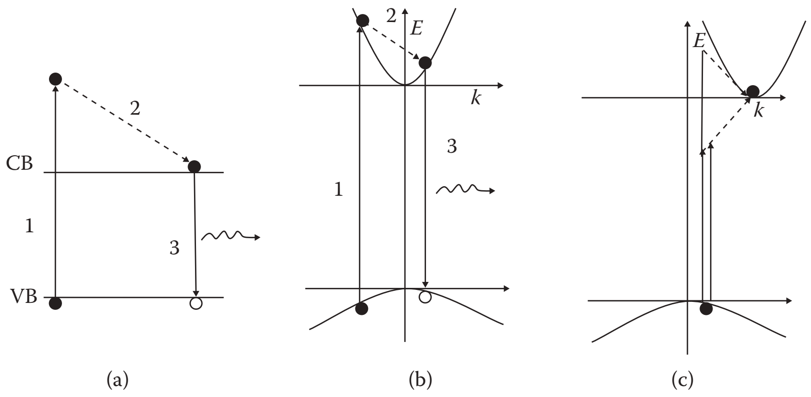

FIGURE 35.2 (a) Absorption (1), relaxation (2), and recombination (3) processes in semiconductors. CB (VB) denotes conduction (valence) band edges; (b) absorption (1), relaxation (2), and recombination (3) processes shown in the E-k diagram of a direct gap semiconductor; (c) the same processes in the E-k diagram of an indirect gap semiconductor. Dashed lines correspond to phonon scattering processes.

line as shown in Figure 35.2b. However, for indirect gap semiconductor, an extra momentum is needed to place the electron in the CB, which is provided by, among other agencies, phonons. In Figure 35.2c, the indirect absorption is indicated by both phonon absorption and emission. The indirect absorption has a very low probability and orders of magnitude being lower than in direct gap semiconductors (Basu 1997).

The variation of light intensity inside a semiconductor, $I(z)$, is governed by the following expression known as the Lambert's law:

$$I(z) = I_0 \exp(-\alpha z), \tag{35.1}$$

where I_0 is the intensity at the surface ($z = 0$), and α is the absorption coefficient of the material, which is a function of photon energy or wavelength.

The absorption coefficient for direct gap semiconductors is much higher than for indirect gap semiconductors.

35.2.2.1 Absorption in Direct Gap Semiconductors

As mentioned already, the absorption process in a direct gap semiconductor is indicated by a vertical line in the E-k diagram. The absorption coefficient in direct gap semiconductors is calculated by using the first-order time-dependent perturbation theory and the Fermi golden rule. The expression for absorption coefficient is of the form (Basu 1997)

$$\alpha(\hbar\omega) = A\left(\hbar\omega - E_g\right)^{1/2}\left[f_c - f_v\right), \hbar\omega \geq E_g, \tag{35.2}$$

where the prefactor A contains the fundamental constants, material parameters such as permittivity, etc., and $f_{c(v)}$ denotes the Fermi occupation probabilities of electrons in the CB (VB).

35.2.2.2 Absorption in Indirect Gap Semiconductors

Since a photon and a phonon are involved in the absorption process, the second-order perturbation theory is used to calculate the absorption coefficient in indirect gap semiconductors. The expression takes the

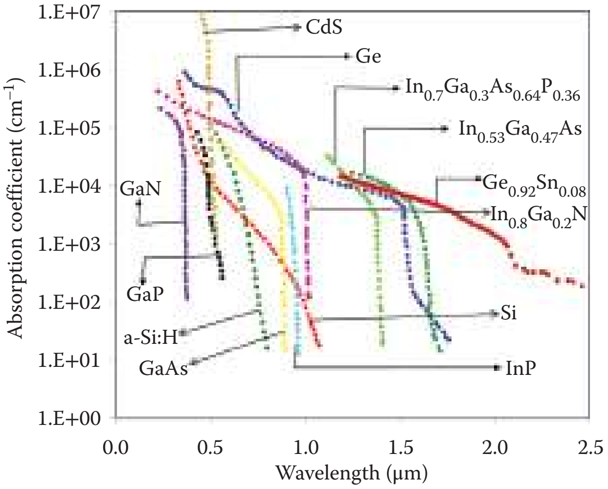

FIGURE 35.3 Absorption spectra of some common semiconductors.

following form at 0 K when a single type of phonon of energy $\hbar\omega_p$ is involved (Basu 1997):

$$\alpha(\hbar\omega) = A_a\left(\hbar\omega - E_g + \hbar\omega_p\right)^2 + A_e\left(\hbar\omega - E_g - \hbar\omega_p\right)^2, \tag{35.3}$$

where the first and second terms correspond, respectively, to the absorption followed by phonon absorption and that followed by phonon emission, and the prefactors A's are distinguished by the corresponding suffixes. There is, in general, a possibility of involvement of different types of phonons. Figure 35.3 shows typical absorption coefficients of some representative semiconductors.

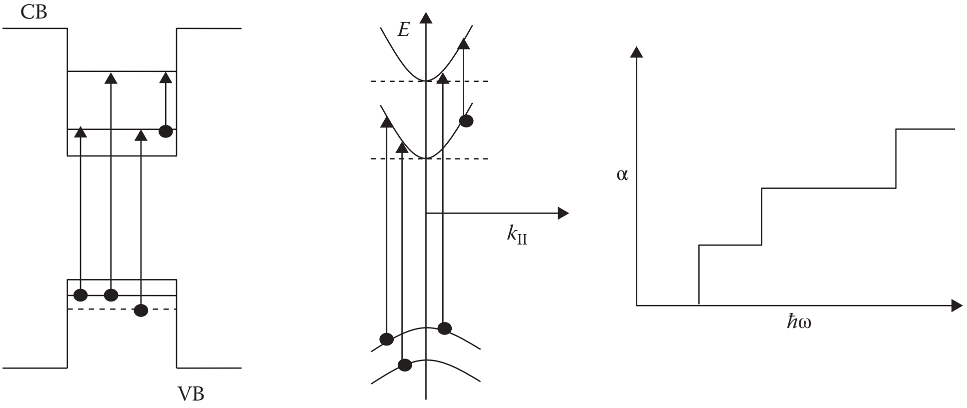
35.2.2.3 Absorption in Quantum Nanostructures

Recent detectors make increasing use of quantum nanostructures such as quantum wells (QWs), quantum wires (QWRs), and quantum dots (QDs), rather than the bulk semiconductors. In QWs, for example, the thickness of the layer of interest is comparable to the de Broglie wavelength of the particle. A QW is realized by sandwiching a thin layer of GaAs between two layers of a higher gap material such as $Al_xGa_{1-x}As$. The typical band diagram of the QW is shown in Figure 35.4a. Due to very small thickness d (<de Broglie wavelength) of GaAs, the motion of electrons and holes is quantized, and assuming that the barrier heights are infinite, the quantized energy levels, or subbands as they are called, are expressed as follows:

$$E_n = \frac{\hbar^2}{2m_{\text{eff}}}\left(\frac{n\pi}{d}\right)^2, \quad n = 1, 2, 3, \ldots. \tag{35.4}$$

The effective mass, m_{eff}, is to be replaced by the electron effective mass, m_e, heavy hole effective mass, m_{hh}, and light hole effective mass, m_{lh}, in order to calculate the respective subband energies (Basu 1997).

The absorption processes in a QW are shown in Figure 35.4b. Here, transitions can occur in several ways. An electron from a valence subband (both lh and hh) can absorb a photon and can come to one of the subbands in the CB. This is a typical band-to-band absorption; however, the absorption threshold, that is, the photon energy marking the sharp rise in the absorption coefficient, increases from the threshold in bulk material that equals the bandgap (Equation 35.2). In addition, an electron (or a hole) in a lower subband (i) can absorb a photon and may move up to a higher subband (j) in the same band. This is a representative intersubband transition. The absorption processes in QWs are governed by some selection rules.



(a) (b) (c)

FIGURE 35.4 (a) Band diagram and quantized energy levels or subbands in a QW structure; (b) optical absorption processes in a QW; both band-to-band and intersubband processes are shown; (c) idealized absorption spectra for QWs. α and $\hbar\omega$ denote the absorption coefficient and the photon energy, respectively. k_{II} is the wave vector along the QW layer plane. CB (VB) denotes conduction (valence) band edges.

The idealized band-to-band absorption coefficient in the QW of a direct gap semiconductor takes the following form (Basu 1997):

$$\alpha(\hbar\omega) = K\sum_{n} H\left[\hbar\omega - E_{\mathrm{nn}}\right), \tag{35.5}$$

where the prefactor K contains fundamental constants, effective (reduced) masses of electrons and holes, and the permittivity of the QW material. In Equation 35.5, H is a Heaviside step function, and E_{nn} is the energy difference between nth hole and nth electron subband.

Typical absorption spectra for QWs obtained from Equation 35.5 are shown in Figure 35.4c, which indicates that the spectra are staircase like.

The idea can be extended to the cases of QWRs and QDs, in which the motion of the particles is inhibited along two and three directions, respectively.

The absorption spectra get modified when excitonic effects are included. Excitons are complexes formed by the EHP bound by the mutual Coulomb interaction.

35.3 Important Characteristics

In this section, some of the important characteristics of PDs are discussed.

35.3.1 Wavelength Selectivity

Different materials are used for the detection of photons at different wavelengths. The wavelength range covered by a particular material is determined by the cutoff wavelength, above which the absorption by it is negligibly small. The cutoff wavelength is determined by the expression $\hbar\omega = E_{\mathrm{g}}$, where E_{g} is the bandgap, from which it is simple to write

$$\lambda_c = \frac{hc}{E_{\mathrm{g}}} = \frac{1.24}{E_{\mathrm{g}}(\mathrm{eV})}\,\mu\mathrm{m}. \tag{35.6}$$

For a bandgap of 1 eV, the cutoff wavelength is 1.24 μm.

35.3.2 Quantum Efficiency

Quantum efficiency (QE), sometimes called the internal quantum efficiency (IQE), is the ratio of the generated EHPs and the number of incident photons. The higher the QE is, larger is the sensitivity of the PD and it is therefore an important figure of merit.

More practical measure of the sensitivity is the external QE (EQE), which is the ratio of EHPs collected at the terminals to the number of incident photons. EQE is less than IQE since a part of the incident photon flux is reflected at the surface and some EHPs are lost by recombination at the surface or by nonradiative processes. EQE is a function of wavelength.

Let I_{pc} be the photocurrent, P_i be the incident power, and $\hbar\omega$ be the photon energy. By definition,

$$\eta = \frac{\text{electron generation rate}}{\text{photon incidence rate}} = \frac{I_{\mathrm{pc}}/e}{P_i/\hbar\omega} = \frac{I_{\mathrm{pc}}}{P_i}.\frac{\hbar\omega}{e} = \frac{1.24}{\lambda\,(\mu\mathrm{m})}\frac{I_{\mathrm{pc}}}{P_i}. \tag{35.7}$$

Equation 35.7 may also be written as a product of three factors as follows:

$$\eta = \zeta(1 - e^{-\alpha d})(1 - R). \tag{35.8}$$

In Equation 35.8, ζ is the fraction of the photogenerated carriers that reach the outer circuit without recombination, the second term within parentheses denotes the fraction of light absorbed in the absorption region of width d, and the last term represents the amount of light transmitted into the semiconductor, R being the reflection coefficient.

35.3.3 Responsivity

Responsivity is defined as the ratio of the primary photocurrent without gain, I_{pc}, and the incident optical power and is expressed as

$$\mathfrak{R} = \frac{I_{\mathrm{pc}}}{P_l} = \eta(\lambda)\left[\frac{e}{(hc/\lambda)}\right]. \tag{35.9}$$

In PDs, responsivity, or sensitivity as it is alternately called, may be increased by increasing the absorption region thickness and minimizing reflection from its surface. The latter can be accomplished by coating the surface with an antireflection (AR) coating of refractive index $n_{\mathrm{AR}} = \sqrt{n_{\mathrm{air}} n_{\mathrm{SC}}}$, where the subscripts refer to AR material, air, and semiconductor, respectively.

35.3.4 Response Time

The speed of response of PDs is limited by three main factors, as discussed next.

35.3.4.1 Diffusion Time of Carriers

The time taken by carriers to diffuse a distance d is given by (Streetman and Banerjee 2016)

$$\tau_{\mathrm{diff}} = \frac{d^2}{2D}, \tag{35.10}$$

where D is the diffusion constant. Diffusion is a slower process than drift. The carriers that are optically generated within a diffusion length from the depletion layer of a photodiode move to the depletion layer by this slow process. The photogenerated current pulse due to a narrow optical pulse shows “tails” due to the slow diffusion process.

35.3.4.2 Drift Time through Depletion Region

The drift velocity of both electrons and holes in a semiconductor attains a saturation value in the presence of very high fields (Streetman and Banerjee, 2016). Usually, a high electric field exists in the depletion layer of a reverse-biased junction. The longest transit time of carriers in the depletion layer of width W may therefore be written as follows:

$$\tau_{\text{drift}} = \frac{W}{v_{\text{sat}}}, \tag{35.11}$$

where v_{sat} is the saturation velocity of the carrier, which is different for electrons and holes. The maximum speed of operation in a PD is limited by transit time.

35.3.4.3 Junction Capacitance Effect

The electrical equivalent circuit of a PD using a p-i-n diode as an example is shown in Figure 35.5. It includes a photogenerated current source (I_{ph}), the depletion layer capacitance (C_{J}), a series resistance (R_{S}) due to bulk resistance and ohmic contacts, a parasitic capacitance (C_{P}), and a load resistance (R_{L}). The electrical 3-dB bandwidth may be expressed as

$$f_{\text{3dB}} = \frac{1}{2\pi(C_{\text{J}} + C_{\text{P}})(R_{\text{L}} + R_{\text{S}})}. \tag{35.12}$$

35.3.5 Noise Equivalent Power and Detectivity

The term *noise* refers to unwanted electrical signal that masks the signal to be detected. Several noise sources, such as thermal, shot, dark current, and flicker noise, are present in PDs and associated circuits and make it difficult to detect weak signals. The minimum detectable signal corresponds to an rms output signal equal to that generated by noise. The signal-to-noise ratio (SNR) is then unity. The noise equivalent power (NEP), a measure of the minimum detectable signal, is defined as the power of sinusoidally modulated monochromatic optical signal that generates the same rms output power in the ideal noise-free detector as the noise signal produced in a real detector.

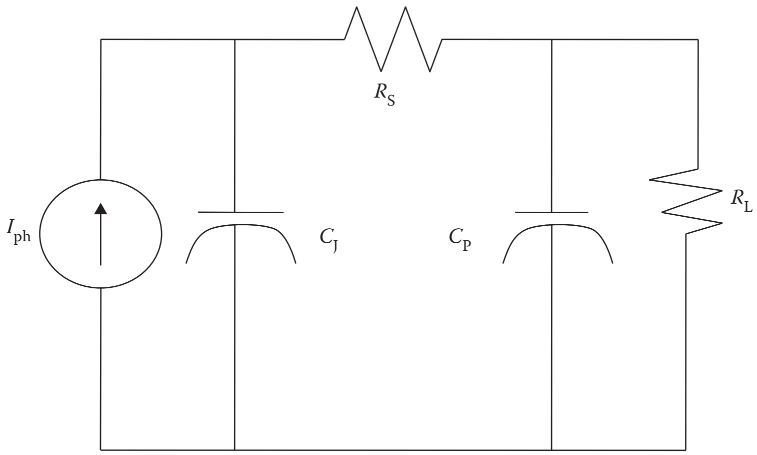


FIGURE 35.5 Electrical equivalent circuit of a photodiode. I_{ph} is the photogenerated current, and C_{J} and C_{p} are, respectively, the junction and parasitic capacitances. R_{S} and R_{L} are, respectively, the series and load resistances.

A unit NEP^* is defined as

$$NEP^* = \frac{NEP}{(A\Delta f)^{1/2}}, \tag{35.13}$$

where $A$is the area of the detector and Δf the bandwidth. The commonly used parameter is, however, the specific detectivity D^*, which is the reciprocal of NEP^*.

35.4 Classification of PDs

PDs can be classified in different ways. It may be an intrinsic or an extrinsic type. In the former, the absorption is band to band and the excess EHPs created produce a photocurrent. In the extrinsic types, the photon energy is less than the bandgap energy, and an impurity or deep-level defect in the forbidden gap is involved. An electron from this deep level is lifted by photon absorption process to the CB. Alternately, an electron in the VB may come to the deep level by photon absorption leaving behind a hole in the VB. In both the cases, the excess carriers created produce photocurrent. The absorption may also take place between two confined states in the CB or VB in a QW, QWR, or QD. Such processes give rise to the intersubband transitions.

PDs can be of two types: with or without internal gain. Photoconductors, avalanche PDs (APDs), and phototransistors show internal gain, that is, the primary photocurrent is multiplied. On the other hand, p-n or rather p-i-n PDs do not have any gain.

In another classification scheme, PDs may be classified as having either vertically illuminated or horizontally illuminated structures. In the former type, the absorbing layer thickness is low to reduce the transit time and to be useful for high-speed operation, though sacrificing the QE. However, a high packing density of arrays of PDs can be achieved, also facilitating coupling of the PDs with fibers. The low QE may be increased by enclosing the active layer within a resonant cavity structure, which is realized by using multilayer dielectrics (Unlu et al. 2001).

The simplest example of a horizontally illuminated PD is an edge-illuminated detector. However, due to diffraction, light spreads outside the high-field region and slow diffusion process leads to tails in the impulse response. The problem may be solved by using a waveguide structure, confining the light into the high-field region covering the optical waveguide. The speed of the devices is limited by the capacitance due to a thin intrinsic absorbing layer. A traveling wave detector may solve the limitations due to capacitance.

Another way of classifying the PDs is based on the type of absorbing layer. Various possibilities exist that include (1) bulk semiconductor, (2) QWs/multiple QWs (MQWs), (3) QWRs, (4) QDs, (5) strained quantum nanostructures, and (6) quantum nanostructures of different band alignments (see Basu 1997) such as type I, type II, type III, etc., as the active absorbing region.

35.5 Different PD Configurations

In this section, we shall discuss the structure and working principles of photoconductors, p-i-n and APDs, and PDs involving intersubband transitions. PDs relying on extrinsic processes will not be addressed. Detailed discussions about different types are given in many text books and reviews (see, for example, Bhattacharyya 1996; Bowers and Burrus 1987; Bowers and Wey 1995; Deen and Basu 2012; Kaiser 2013; Senior and Jamro 2009)

35.5.1 Photoconductive Detectors

The simplest form of PD is a photoconductor, in which the conductivity of the semiconductor is changed by absorption of photons. The changed photoconductivity produces photocurrent proportional to the incident optical power. In this section, the structure, principle, and noise analysis of such photoconductive detectors are presented.

35.5.1.1 Structure and Analysis

Consider a slab of semiconductor of length L, width W, and thickness d as shown in Figure 35.6. A voltage V is applied across the length and the slab is illuminated by light at the top. The current I flowing through the photoconductor may be expressed as

$$I = eWd(n\mu_e + p\mu_h)\left(\frac{V}{L}\right) = eWd\left(\frac{V}{L}\right)[(n_0\mu_e + p_0\mu_h) + (\Delta n\mu_e + \Delta p\mu_h)] = I_D + I_{ph}, \tag{35.14}$$

where I_D is the dark current, I_{ph} is the photocurrent, n_0 and p_0 are the equilibrium electron and hole concentrations, respectively, Δn (Δp) is the excess electron (hole) concentration, and μ_e (μ_h) is the electron (hole) mobility.

The average generation rate r_g within the photoconductor is expressed as follows:

$$r_g = \frac{\eta I_0 WL}{\hbar\omega WLd} = \frac{\eta I_0}{\hbar\omega d}, \tag{35.15}$$

where η is the efficiency, I_0 the light intensity at the surface, and $\hbar\omega$ the photon energy. Under steady state, the generation rate equals the recombination rate so that $r_g = r_r = \Delta n/\tau = \Delta p/\tau$, where τ is the recombination lifetime. Thus, one obtains

$$\Delta n = \Delta p = r_g\tau. \tag{35.16}$$

Substituting Equation 35.16 in Equation 35.14, the photocurrent is obtained as follows:

$$I_{ph} = \frac{Wd}{L} r_g\tau e(\mu_e + \mu_h)V. \tag{35.17}$$

The photoconductive gain, defined as the ratio of the rate of flow of electrons from the device to the rate of generation of EHPs within the device, takes the following form:

$$G = \frac{I_{ph}}{e}\frac{1}{r_g WLd} = \frac{\tau(\mu_e + \mu_h)V}{L^2}. \tag{35.18}$$

Equation 35.17 has been used to arrive at the last equality in Equation 35.18. The variation in gain with voltage V may be understood if we assume that $\mu_e >> \mu_h$, which is usually the case. The transit time of electrons through the device is $\tau_{tre} = L^2/\mu_e V$ and from Equation 35.18 $G = \tau/\tau_{tre}$. At low bias, $\tau < \tau_{tre}$ and the gain is <1. With larger V, electrons move faster, $\tau > \tau_{tre}$, and the gain becomes larger than unity.

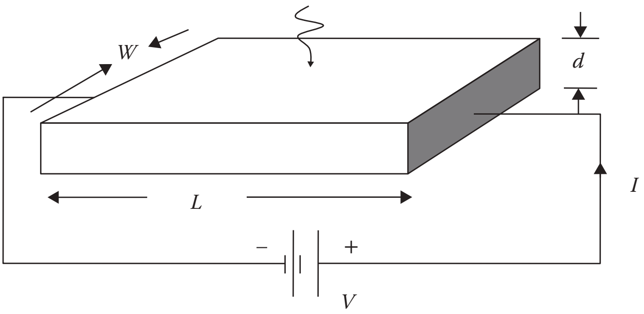

FIGURE 35.6 Schematic of a photoconductive PD. L, W, and d are the length, width, and depth of the photoconductor, respectively. V is the applied voltage and I is the current.

At still larger bias, the velocities of both electrons and holes are saturated. The gain is again reduced below unity. By following these arguments, it is easily concluded that higher values of gain may be achieved by increasing V, or by decreasing L, or by increasing the recombination lifetime.

35.5.1.2 Noise in Photoconductors

There are three main sources of noise in a photoconductive detector. The first is thermal or Johnson noise that arises due to random motion of carriers in the device. The mean squared noise current due to a conductor having finite resistance R is given as follows:

$$\left\langle i_{\mathrm{th}}^2 \right\rangle = \frac{4k_{\mathrm{B}}TB}{R}, \tag{35.19}$$

where B is the bandwidth of the device. In developing the noise equivalent circuit, the noisy photoconductor is replaced by a noiseless photoconductor and an ideal noise current or voltage generator.

Fluctuations in generation and recombination rates give rise to fluctuations in current and hence generate noise. The mean squared generation-recombination (GR) current is expressed as follows:

$$\left\langle i_{\mathrm{GR}}^2 \right\rangle = \frac{4eGI_0B}{1+\omega^2\tau^2}, \tag{35.20}$$

where I_0 is the steady photogenerated current. GR noise is also termed as shot noise. Since shot noise decreases as ω^{-2}, the thermal noise is the dominating noise source at high frequencies.

The third kind of noise, the flicker noise, has its origin in the presence of surface and interface defects and traps in the bulk material, and the mean squared current is expressed as:

$$\left\langle i_f^2 \right\rangle \propto \frac{1}{f}. \tag{35.21}$$

Equation 35.21 indicates that flicker noise is of importance at very low frequencies, less than 1 KHz.

In the noise equivalent circuit, the noise current sources appear in parallel. Assuming that the noise sources are uncorrelated and also that flicker noise is negligible, one may write for the SNR as

$$\frac{S}{N} = \frac{i_{\mathrm{ph}}^2}{\left\langle i_{\mathrm{th}}^2 \right\rangle + \left\langle i_{\mathrm{GR}}^2 \right\rangle}. \tag{35.22}$$

Let us assume that the optical signal incident on the detector is sinusoidally modulated by a modulating signal of angular frequency ω_{m}, and its power variation has the form $P_1 \exp(j\omega_{\mathrm{m}}t)$. The rms optical power is $P_1/\sqrt{2}$. The rms photocurrent is expressed as

$$i_{\mathrm{ph}} = \frac{eP_1\eta}{\sqrt{2}\hbar\omega}\frac{\tau}{\tau_{\mathrm{tr}}}\frac{1}{\left[1+\omega_{\mathrm{m}}^2\tau^2\right)^{1/2}}. \tag{35.23}$$

In arriving at Equation 35.23, the expression for responsivity, Equation 35.9, has been used to relate photocurrent with power and the gain is replaced by the ratio τ/τ_{tr}. The SNR as given by Equation 35.22 may now be written by using Equations 35.21 through 35.23 as

$$\frac{S}{N} = \frac{\eta P_1^2}{8B\hbar\omega P_0}\frac{1}{1+\frac{k_BT}{eG}\left[1+\omega_{\mathrm{m}}^2\tau^2\right)\frac{1}{RI_0}}. \tag{35.24}$$

35.5.2 p-n Photodiode

The simplest PD without internal gain is a reverse-biased p-n junction, shown schematically in Figure 35.7 along with the electric field profile. Both depletion and diffusion regions are shown. Photons are absorbed in the absorption region ($\sim 1/\alpha(\lambda)$). In case of weak absorption, the absorption region may cover the whole device, a part of which may contain the depletion region. Note that EHPs are generated in both the depletion and diffusion regions. While the electric field in the depletion region sweeps the photogenerated carriers quickly, the EHPs created in the diffusion region move slowly and thus limit the response of the PD. To improve the response, it is to be ensured that all photons are absorbed in the depletion region. Therefore, its width is made as large as possible by using lower doping.

35.5.3 p-i-n Photodiode

An efficient way to overcome the limitations of a p-n PD is to use a p-i-n configuration. Near the absorption edge, the weak absorption coefficient makes the absorption region quite long. The depletion region must match this, and to achieve this, the n region is low-doped to make it intrinsic (i). To make a low-resistance contact, a heavily doped n layer (n^+) is added. The resulting structure, a p-i-n structure, is shown in Figure 35.8 including the electric field profile, depletion and absorption regions. As shown, in this structure, the EHPs created are subject to the depletion layer field.

The speed of response of the p-i-n photodiode depends on (1) the transit time of carriers across the depletion layer as given by Equation 35.11 and (2) the RC time constant, where C is the junction capacitance.

The junction capacitance may be used either by using a mesa structure or by using a planar geometry with selective diffusion in the contact region (Bandyopadhyay and Deen 2001). The capacitance may also be reduced by increasing the width of the i layer. This increases the absorption and hence the QE, but increases the transit time, thereby decreasing the speed of response. To have high values of both QE and

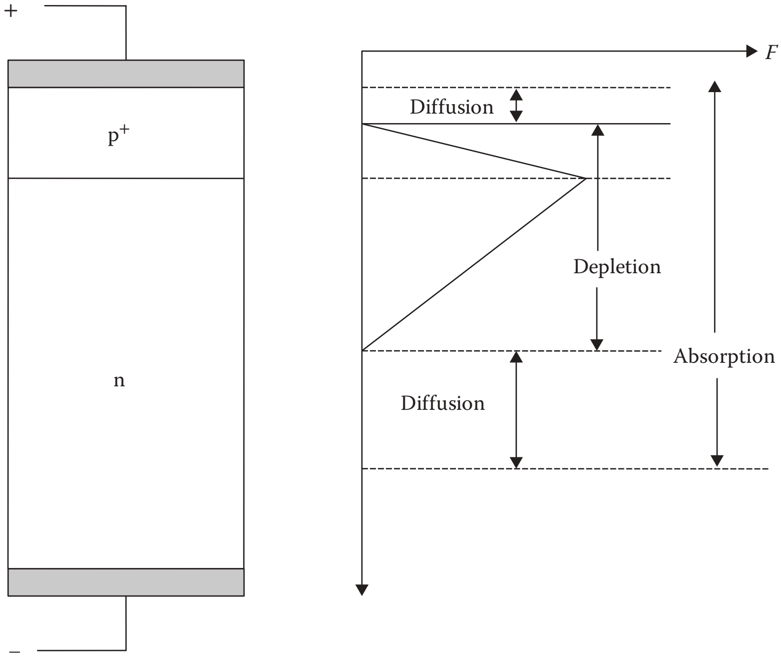

FIGURE 35.7 p-n PD structure (left) and electric field profile across the depth of the device (right). The depletion, diffusion, and absorption regions are shown.

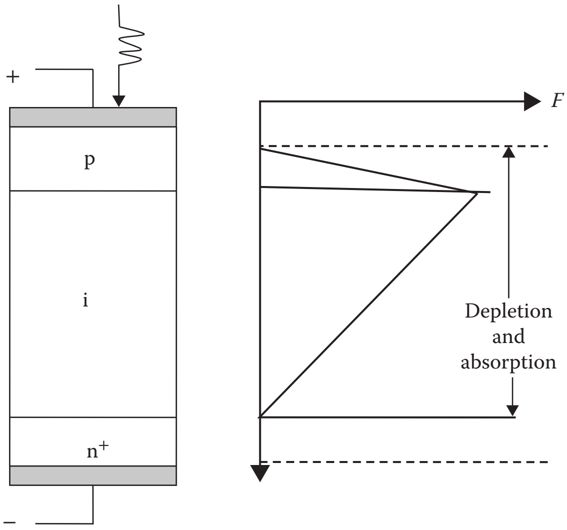

FIGURE 35.8 The p-i-n photodiode structure (left) and absorption and depletion regions and electric field (F) profile in the device (right).

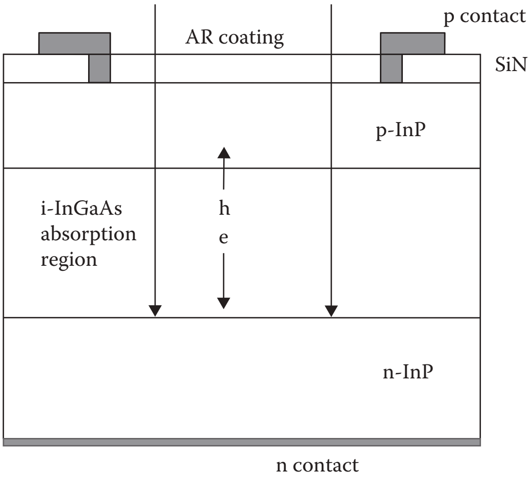

FIGURE 35.9 A cross-sectional view of a vertically illuminated p-i-n photodiode using p-InP/i-InGaAs/n-InP and SiN as antireflection (AR) coating.

speed (or bandwidth), the usual methods are (1) to employ an edge-illuminated structure or (2) to use a resonant-cavity-enhanced (RCE) structure.

A typical structure for a vertically illuminated p-i-n PD is shown in Figure 35.9. The n and p layers may be InP and the i layer is an undoped (or unintentionally doped) InGaAs layer. Since InP is transparent to 1.3–1.55 μm, the incident light is absorbed in the InGaAs layer, in which the electric field appears. Thus, there is no recombination or diffusion of the carriers. This leads to a fast response. The area of the absorbing layer must be optimized for giving high-speed operation (Bandyopadhyay and Deen 2001; Beling and Campbell 2009).

Edge-illuminated and RCE structures are presented in subsections 35.6.1 and 35.6.2, respectively.

35.5.4 Avalanche Photodiodes

APDs possess internal gain and as such are used to detect very weak optical signals. The working principle of an APD is discussed first and then some of the structures for improved performance are presented. The noise performance of APDs is discussed next.

35.5.4.1 Principles

The internal gain arises due to impact ionization in the presence of a high electric field in the depletion layer. A primary electron gets enough kinetic energy to break a covalent bond, thereby creating one secondary EHP. The primary and secondary carriers are accelerated by the depletion field and may again create tertiary EHPs. The multiplication process gives rise to an increased photocurrent. A primary hole can also initiate the ionization process. By this process, one initial electron or a hole may generate M extra EHPs, where M is the multiplication gain of the PD. In general, the ionization coefficients for electrons (α) and for holes (β) are different. The structure of an APD is shown in Figure 35.10, in which the electric field profile is also included.

In order to cause impact ionization, the carriers must possess a minimum energy, called the ionization threshold, which must exceed the bandgap energy. The ionization thresholds for electrons and holes are different. This leads to different values of ionization coefficients α and β, for electrons and holes, respectively. The ionization coefficient is the reciprocal of the average distance traversed by a carrier in the direction of the electric field to create an EHP. In its motion, a carrier may lose or gain energy via carrier–phonon interaction, which becomes more dominant with rise in temperature, thereby reducing the ionization probability. The breakdown voltage in a p-n junction therefore increases with temperature.

Defects in the device can lead to microplasma effect, in which breakdown at a lower voltage than in the remaining part of the junction occurs in a small area. This needs careful device processing and fabrication.

One of the important performance parameters for a PD used in optical communication is the maximum bit rate of operation. The detector must convert faithfully the incident optical pulses into electrical pulses. This is governed by how quickly the detector current responds to a pulse of photons. At low bias, carriers may be generated in the undepleted region and the response of an APD to an optical pulse may produce

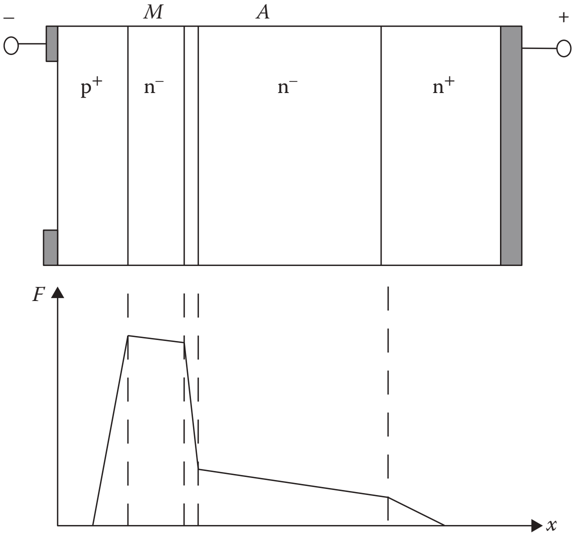

FIGURE 35.10 Structure of an APD (top) and the electric field (F) profile within it (bottom). M and A denote the multiplication and absorption regions, respectively.

a diffusion tail in the current pulse as in a p-i-n diode. When the bias is high enough to fully deplete the junction, the following three factors contribute to the response time:

1. Transit time of the carriers across the absorption layer of width W, given by Equation 35.11
2. The time taken by the carriers to create EHPs by avalanche multiplication
3. The RC time constant, where R is the device and load resistance and C is the junction capacitance

For low gain, the response time is determined by the transit time and the RC time constant. These two limit the value of bandwidth. When the gain is large, avalanche multiplication time becomes dominant and the bandwidth is reduced. APDs are therefore characterized by a constant gain bandwidth product.

35.5.4.2 Separate Absorption Grading and Multiplication and Separate Absorption, Grading, Charge Sheet, and Multiplication APDs

PDs for optical communication at a wavelength of 1.55 μm have $In_{0.53}Ga_{0.47}As$ as the absorbing layer. The usual p-n junction shows a high dark current due to the low bandgap of InGaAs. Furthermore, at high reverse field in the depletion region, the breakdown may be due to tunneling as opposed to the avalanche process. Therefore, the p-n junction is made using InP. The design involves separate absorption and multiplication (SAM). In an SAM structure, a sufficiently high electric field exists to cause avalanche multiplication in InP, and at the same time the field is low enough to prevent tunneling in the lower bandgap InGaAs layer in which optical absorption takes place. However, the photogenerated holes in the InGaAs layer while flowing toward InP layers find a band offset ΔE_v at the InGaAs/InP interface. Holes are thus trapped at the heterointerface, giving rise to a slower response. Incorporation of one or more layers of intermediate gap InGaAsP in between the absorption and multiplication regions eliminates this problem. The structure is called a separate absorption grading and multiplication (SAGM) structure.

The presence of quaternary and ternary layers in SAGM structures leads to another problem. The ionization rate of holes is higher than that of electrons in InP, but is lower in both the InGaAs and InGaAsP layers. This may give rise to unwanted multiplication in the ternary and quaternary layers. As the ionization ratio k approaches unity there, higher noise and lower speed are expected. The doping and thickness of the multiplication layer should be accurately controlled in order to have the increased gain–bandwidth product. A planar SAGM APD that avoids premature edge breakdown employs a partial charge sheet layer in between the multiplication layer and the grading region. The structure is known as a separate absorption, grading, charge sheet, and multiplication (SAGCM) structure. The structure consists of a lightly (or unintentionally) doped wide gap multiplication region where the field is high and an adjacent doped charge layer or a field control region. The presence of the charge (C) layer offers an extra degree of freedom such that the electric field profiles in the active region and in the periphery of the device can be controlled independently.

A cross-sectional view of an SAGCM APD using InP multiplication, InP charge, InGaAsP grading, and InGaAs absorption layer is shown in Figure 35.11. APDs used in telecommunications are reviewed by Campbell (2007).

35.5.4.3 Noise in APDs

Three important noise sources are operational in p-i-n PDs and in APDs. They are (1) thermal noise, (2) dark current noise, and (3) shot noise. In addition, APDs are characterized by an excess noise due to the random nature of the avalanche multiplication process. The statistical variation of multiplication is responsible for multiplication excess noise. The excess noise factor F depends on the ratio $k = \alpha/\beta$ and is expressed as

$$F = kM + (1-k)\left(2 - \frac{1}{M}\right) = M\left\{1 - \left[(1-k)\left(\frac{M-1}{M}\right)^2\right]\right\}. \tag{35.25}$$

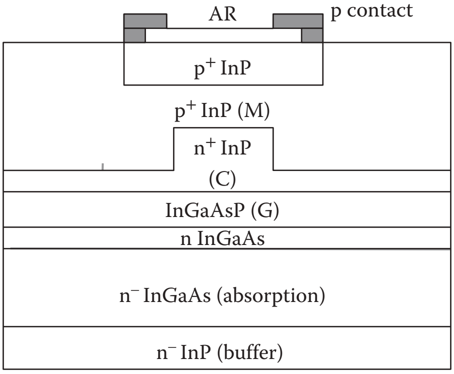

FIGURE 35.11 Cross-sectional view of an SAGCM APD. Antireflection (AR), multiplication (M), charge sheet (C), and graded (G) regions are shown.

The excess noise factor therefore reduces with large value of k. The total dark current in an APD is given by

$$I_\mathrm{d} = I_\mathrm{s} + I_\mathrm{dm} M, \tag{35.26}$$

where I_s is the unmultiplied surface current, and I_dm is the unmultiplied dark current. Let I_ph0 be the primary DC photocurrent, I_bk the photo-induced background current, and B the bandwidth. The mean square shot noise current is then

$$\langle I_M \rangle^2 = 2e\left[I_\mathrm{s} + \left(I_\mathrm{dm} + I_\mathrm{bk} + I_\mathrm{ph0}\right) M^2 F\right] B. \tag{35.27}$$

The SNR of APD is written as

$$\mathrm{SNR} = \frac{M^2 I_\mathrm{ph0}^2}{\langle I_M \rangle^2 + \left(4k_\mathrm{B}TB/R\right)} = \frac{M^2 I_\mathrm{ph0}^2}{2e\left[I_\mathrm{s} + \left(I_\mathrm{dm} + I_\mathrm{bk} + I_\mathrm{ph0}\right) M^2 F\right] B + \left(4k_\mathrm{B}TB/R\right)}. \tag{35.28}$$

In the above expression, the thermal noise contribution $\left(4k_\mathrm{B}TB/R\right)$ has been included. Note that by putting $M = 1$ and $F = 1$, we may obtain the SNR for p-i-n PD.

It is easy to assess the relative contributions of the shot noise (first term in the denominator of Equation 35.28) and of the thermal noise term (second term in the denominator), by dividing the numerator and denominator by M^2. The shot noise increases with M as does F. However, the thermal noise decreases with M as M^{-2}. It appears therefore that there exists an optimum value of M for which SNR can be a maximum. The variation of M is effected by change of reverse bias and may be expressed by the following empirical expression:

$$M \approx \frac{1}{\left\{1 - \left(\frac{V_\mathrm{a} - I_\mathrm{ph0}R}{V_\mathrm{B}}\right)^n\right\}}, \tag{35.29}$$

where V_a is the bias voltage, R the effective resistance, V_B the breakdown voltage, and n a constant that depends on the design of the device.

35.5.5 Schottky Barrier PD

In a Schottky barrier (SB) PD, the rectifying junction is formed between a metal and a semiconductor, rather than by a p-n junction. A schematic structure of an SB PD is shown in Figure 35.12, which indicates that the active or absorbing layer is quite narrow. This leads to short transit time and hence higher bandwidth, but to a lower QE.

35.5.6 Metal-Semiconductor-Metal PD

A metal-semiconductor-metal (MSM) PD is shown schematically in Figure 35.13. The schematic layer structure consists of a thin undoped layer grown on a semi-insulating substrate. Metal electrodes are then deposited on the active layer as interdigitated fingers. Each set of fingers forms a Schottky contact with the semiconductor and is connected to a large pad for connection to the external circuit. Both contacts in the MSM PD are on the same side of the substrate. Since the active layer thickness is small, the QE is less than in a p-n PD. Moreover, the reflections from the metal and semiconductor surfaces lead to smaller responsivity. However, the small transit time and very low capacitance greatly enhance the bandwidth.

A contact between a metal and a semiconductor may be either ohmic or rectifying. To obtain a rectifying contact, a certain combination of metal and a given semiconductor is needed. In such a junction, potential barrier develops due to the difference between the work functions of the metal and semiconductor. Another difference between a p-n junction and an SB diode is that both electrons and holes contribute to the current in a p-n junction, whereas SB diodes are majority carrier devices. The MSM PD consists of two junctions,

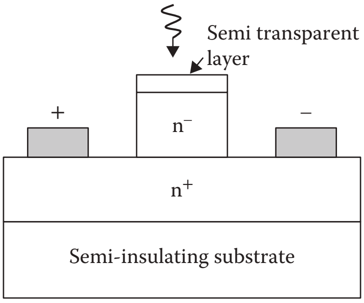

FIGURE 35.12 Schematic diagram of an SB PD. Shaded regions represent metallic contacts.

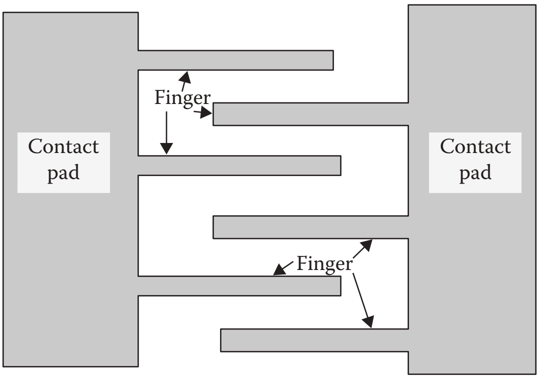

FIGURE 35.13 Top view of an MSM PD showing fingers and contact pads for connection to external circuits.

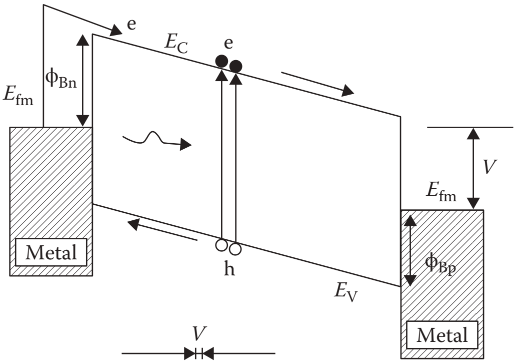

FIGURE 35.14 Band diagram of an MSM PD showing directions of flow of electrons and holes. E_c and E_v are conduction and valence band edges, respectively, E_{fm} is the Fermi level of the metal, ϕ_{Bn} and ϕ_{Bp} are the barrier heights at the n and p sides, respectively, and V is the applied bias between two metallic contacts. The PD is represented by two rectifying contacts shown at the bottom.

both of which may be rectifying or one junction ohmic and the other rectifying. The band diagram of an MSM PD is shown in Figure 35.14, in which the potential barrier ϕ_b is due to the work function difference. The two electrodes are connected serially, back-to-back, and the device contains two diodes as shown in Figure 35.14.

The dark current in the PD is due to the flow of thermally generated EHPs and by carriers from the metal surmounting the potential barrier ϕ_b. Under illumination, excess EHPs are generated and flow of electrons and holes is in opposite directions under the influence of the external bias V, as shown in Figure 35.14.

As stated already in connection with SB PDs, MSM PDs make a compromise between QE and bandwidth. The use of multiple fingers increases the QE. However, to increase the bandwidth, the effective absorption layer thickness needs to be reduced. Introduction of a highly doped layer at a certain depth may restrict the electric field within a certain absorption region and may provide a solution to the bandwidth problem.

Current improved technology may produce very thin fingers with narrow spacings between fingers. This reduces the transit time, but the speed of response is governed by the RC time constant. The following simple analytical expression for the capacitance may be used to calculate the time constant (Averine et al. 2001):

$$C = 0.226NL\varepsilon_0 \left[\varepsilon_S + 1\right) \left[6.5\theta^2 + 1.08\theta + 2.37\right). \tag{35.30}$$

In Equation 35.30, L is the length of a finger, ε_0 is the permittivity of free space, ε_S is the relative permittivity of the semiconductor, and $\theta = (D + t)/t$ is the finger-to-period ratio, where D is the width of the metal finger and t is the gap spacing between the metal fingers.

The EQE is given by

$$\eta = (1 - R)\frac{t}{t + D}\overset{\perp}{1} - \exp(-\alpha d)\big], \tag{35.31}$$

where R is the reflection coefficient, α the absorption coefficient, and d the thickness of the absorption layer of the semiconductor. The QE may be increased by replacing the metal electrodes by transparent conducting indium tin oxide (ITO), thereby reducing R. It can be increased by reducing the finger width at the cost of increased resistance however.

35.5.7 Phototransistors

Phototransistors may be a bipolar junction transistor (BJT) or metal-oxide-semiconductor field-effect transistor (MOSFET). The BJT may be either p-n-p or n-p-n type. It may be used in two-terminal (2T) configuration, with electrical contacts to the emitter and collector with the base floating, or in three-terminal (3T) configuration as in a normal BJT.

We first consider the 2T configuration. The structure is akin to a heterojunction bipolar transistor in which the emitter region is a higher bandgap material. The emitter is transparent to the incident light and thus acts as a window layer; the incident light falls directly on the base and is primarily absorbed in the base, base-collector depletion region, and the collector region. The heterojunction also increases the current gain. The base-collector junction is reverse biased so that the transistor acts as a reverse-biased PD.

Under no illumination the usual collector saturation current flows. However, when light is incident, the photogenerated electrons cross the depletion region in the base-collector junction and are collected at the collector terminal. The photogenerated holes travel in the opposite direction to the emitter terminal, thus reducing the emitter injection efficiency and the current gain.

The incident light is absorbed in the base and the base-collector depletion layer. The collector current for the (2T) configuration is given by (Chand et al. 1985):

$$I_c = I_{ph}(1 + h_{fe}), \tag{35.32}$$

where I_{ph} is the photogenerated current and h_{fe} the common emitter current gain of the BJT. A dark current also contributes to the collector current.

The currently used phototransistors are heterojunction bipolar transistors with larger gap and smaller gap semiconductors forming the emitter and base layers, respectively [see Basu et al. (2015) and Chang et al. (2016)] for work on GeSn-based heterojunction phototransistors and references therein for work on III-V compounds and alloy-based devices).

As stated already, a p-i-n diode is formed by the base, collector, and subcollector of a heterojunction phototransistor (HPT). Under optical illumination in a 2T-HPT, the photocurrent generated within the p-i-n diode is injected across the emitter-base junction and then amplified through transistor action. In this way, both the photocurrent in the p-i-n structure and the dc current gain determine the final collector photocurrent and the optical gain. When the incident optical power is low, the dc current gain is low, thereby making the optical gain low. This situation is improved in a 3T-HPT, in which a dc bias is applied to the base. The bias shifts the operating point to a higher collector current, making the dc current gain and optical gain higher.

A detailed analysis of the 3T-HPT has been presented by Frimel and Roenker (1997a,b) using a thermionic emission-diffusion model. The theory is too lengthy to be included here.

Useful references for 3T-HPTs for III–V compound-based materials as well as recently developed GeSn alloys may be found in Basu et al. (2015) and Chang et al. (2016).

In an MOS phototransistor, light incident at the source-gate region changes the surface potential under the gate oxide. This change causes a change in the current flowing through the channel.

35.5.8 QWIP and QDIP

It has been mentioned in Section 35.4 that the absorbing layer in a PD may contain quantum nanostructures. QWs and MQWs, in particular, are incorporated in the intrinsic (i) layer of a p-i-n PD, an APD, or in the base of a hetero phototransistor. The absorption in MQWs is from a valence subband to a conduction subband.

Quantum well infrared photodetectors (QWIPs) have QWs as the absorbing region, but the transition occurs from one subband to another in the same band, as shown in Figure 35.11. The intersubband

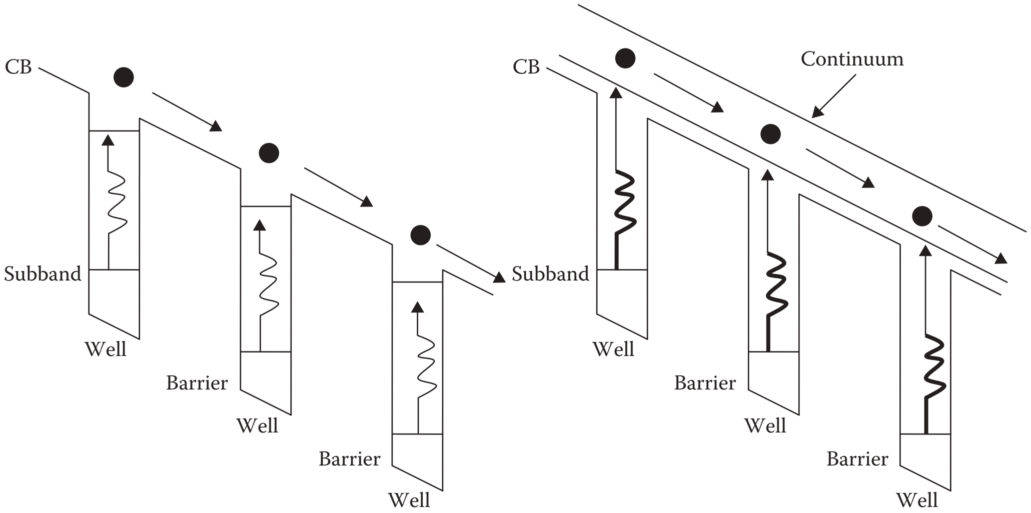

FIGURE 35.15 Intersubband absorption in QWIPs: (a) a bound-to-bound transition and (b) a bound-to-continuum absorption. The movement of electrons (solid balls) is shown in the figures.

transition energy is lower than the energy involved in band-to-band transitions in a QW. The QWIPs therefore work at the mid-infrared range (3–20 μm). Equation 35.4 may be used to calculate the energy difference between two subbands corresponding to the wavelength to be detected (see Equation 35.6). The width of the QW is then calculated from the value of the energy difference.

The types of transitions involved for CB are illustrated in Figure 35.15. The MQWs form the intrinsic layer of a p-i-n structure, in which the reverse bias causes the band bending. As shown in Figure 35.15a, the transition takes place from the lowest subband to the upper subband that lies close to the CB edge in the barrier layer. The electron lifted to the upper subband tunnels to the continuum states in the barrier and is drifted by the built-in electric field. In Figure 35.15b, an electron from the lone lowest subband absorbs the MIR photon and goes to the continuum states in the barrier and is then transported (see Schneider and Liu 2007).

Instead of QWs, multiple stacks of QDs can act as the absorbing layer, and the PD is called a quantum dot infrared photodetector (QDIP) (Barve et al. 2010).

35.5.9 Single-Photon Detectors

Single-photon emitters and detectors are needed for quantum information processing systems. Semiconductor-based single-photon detectors are APDs that operate with reverse bias exceeding the breakdown voltage. In this regime, the gain is enormously high. An incoming photon creates a charge, the number of which is multiplied (avalanche process) until it saturates at a current typically limited by an external circuit. In order that the single-photon APD should respond to a subsequent optical pulse, the saturated avalanche current must be terminated by lowering the bias voltage below the breakdown voltage (Eisaman et al. 2011).

35.6 Improved Devices

The PD structures such as p-i-n, APDs, etc., may show improved performances if some structural or materials modifications are introduced, some of which are discussed briefly in this section.

35.6.1 Waveguide PDs

In all the earlier discussions, vertically illuminated PD structures have been considered. For good PD performance, both the QE and speed of operation must be as high as possible. The absorbing layer in vertically illuminated devices must be very thin in order to reduce transit time; however, the thin layer cannot absorb the incident photons, thereby reducing the QE. To achieve high QE and high speed, edge-illuminating devices are used (Beling and Campbell 2014). The advantage of using waveguide structure has been pointed out in Section 35.4. The waveguide confines the otherwise spreading light into the high-field region. (Beling and Campbell 2014).

The waveguide photodetector (WPD) structure employs waveguides with absorbing layers either embedded in the waveguide or grown adjacent to the waveguide. The edge-coupled structure has been realized in p-i-n, APD, MSM, or uni traveling wave configuration.

The simplest type of edge-illuminated WPD structure is shown in Figure 35.16. The incident light falls directly into the edge of the absorbing layer. Here the direction of propagation of light is normal to the direction of transit of the photogenerated carriers. Note that the incident light may spread outside the absorbing region, making the optical confinement factor low and effective absorption less than in the bulk. However, the absorption length is quite large (~mm) so that responsivity and QE are enhanced. At the same time, the photogenerated carriers traverse a very short distance equal to the thickness of the absorbing layer making the transit time low. The increase in the capacitance due to the thin depletion layer may be arrested by reducing the area of the device. The state-of-the art technology for WPDs is discussed by Beling and Campbell (2014).

One drawback of the edge-coupled WPD is the misalignment of the optical field with the waveguide region. Use of lensed fiber or additional optics can increase the coupling efficiency. A useful way to improve coupling efficiency or to avoid the misalignment problem is to employ the evanescent waveguide structure as shown in Figure 35.17. In this configuration, the absorbing layer is placed adjacent to the waveguide core. The optical coupling is enhanced by inserting a transition layer between the waveguide and the detector. Since the waveguide mode has a smaller cross-section than that of a single-mode fiber, the input coupling efficiency is increased by using different approaches, for example, using a spot-size converter.

35.6.2 RCE Structure

The performance of a PD can be enhanced by placing the active device structure inside a Fabry–Pérot cavity. The cavity acts as a resonant structure providing wavelength selectivity and a large enhancement of the optical field, which in turn allows thinner PD layer. The device shows faster response and increased QE at the resonant wavelength. The wavelength selectivity and high-speed response make the devices the right candidates for wavelength division multiplexing applications (Unlu et al. 2001).

Photonic crystal structures have been employed to realize nanoscale PDs offering ultralow capacitance, thereby increasing the bandwidth and enabling ultralow power operation (Nozaki et al. 2013) (Figure 35.16).

35.6.3 Incorporation of Heterojunctions and Quantum Nanostructures

The active materials for detection are usually grown on a suitable substrate leading to heterojunctions. However, heterojunctions and MQWs and stacks of QDs are also used in the active regions of PDs. The heterostructures extend or control the range of wavelength to be detected. For example, in Ge_xSi_{1-x}/Si heterostructures or MQWs, the absorption takes place in the lower gap alloy material, and the heterobarrier prevents leakage of carriers, thus reducing the dark current.

35.7 Materials

The wavelength range covered by a PD depends on the active material, the bandgap of which determines the maximum wavelength (cutoff wavelength). Table 35.1 includes a few important materials and the corresponding wavelength range.

TABLE 35.1 Photodetector Materials and the Wavelength Range Covered

Material	Bandgap (eV)	Wavelength Range (μm)	Substrate
GaAs	1.42	<0.87	GaAs
$In_{0.53}Ga_{0.47}As$	0.81	1.3–1.6	InP
Si	1.12	0.2–1.12	Si
Ge	0.66	<1.8	Si
$Si_{1-x}Ge_x$	1.12–0.66	<1.8	Si
$Si_{1-x}Ge_x$/Si QWs	1.12–0.66	2–12	Si
$Ge_{1-x}Sn_x$ ($x > 0.08$)	0.58– ∼ 0	1.2–2.2	Si
GaAlAsSb/GaSb	0.60	0.75–1.9	GaSb
InGaAlAs/InGaAs/InP	–	0.5–2.1	InP
HgCdTe/CdTe	–	0.8–2.0	CdTe
$Ga_{1-x}Al_xN$	0.38–0.22	0.36–<0.2	Sapphire

36.1 Introduction

Semiconductor p-n junction photodiodes have been available for half a century. By applying an electric field across the p-n junction, the light-generated carriers create an electrical current flow, thus the p-n junction photodiodes can convert optical signals into electrical signals (Shi and Li, 2014). Sensing applications in infrared, visible, and ultraviolet spectral bands promote theoretical research of these photodiodes. Numerical simulations, containing structural details such as layer thicknesses, doping profiles, and trap concentrations, provide key insights into device design and reliability degradation mechanisms, which could effectively reduce costly and time-consuming testing when developing and characterizing a new semiconductor device or technology. However, simulations of p-n junction photodiodes involve many important physical models, which play a decisive role in the calculations of accurate results. This chapter covers some basic equations and models used in the simulations of p-n junction photodiodes. Another key point is the accurate knowledge of device material parameters. Because of the complexity of an actual device structure, different device and material parameters are needed for various designs and structures. A number of these characteristic input parameters required for accurate modeling when building a basic theoretical framework are explained in this chapter.

First, this chapter presents several basic equations and models in detail. Second, principles and characteristics of several common optical generation models are reviewed and compared. Then, a number of important characteristic input parameters are introduced. Several p-n junction photodiode simulation examples are listed in the end of this chapter.

Figure 36.1 presents the general process simulation of p-n junction. After building the device structure, the device model could be defined by adding mesh generation and doping for different region. Different physical models are added in the optical/electrical simulation step, and then the desired information could be achieved. Figure 36.2 examples the results of some of the important characteristics of p-n junction.

36.2 Basic Equations and Models

Physical phenomena in semiconductor devices are very complicated and, for different devices and materials, models of different levels of complexity are needed in simulations. Different partial differential equations and models determine different microscopic physical mechanisms in a simulation, and can depend on different materials and device structures. This chapter introduces a number of widely used basic equations and models.

Depending on the p-n junction photodiodes under investigation and the level of modeling accuracy required, there are three governing equations for charge transport in semiconductor devices: *the Poisson equation* and *the electron and hole continuity equations*. The Poisson equation is as follows:

$$\nabla\varepsilon \cdot \nabla\psi = -q\left(p - n + N_{D^+} - N_{A^-}\right) \tag{36.1}$$

where ε is the electrical permittivity, ψ is the electrostatic potential, q is the elementary electronic charge, n and p are the electron and hole densities, N_{D^+} is the number of ionized donors, and N_{A^-} is the number of ionized acceptors. The electron and hole continuity equations are written as:

$$\frac{1}{q}\nabla\overrightarrow{J_n} + \left(G^{\text{opt}} - R\right) = 0 \tag{36.2}$$

$$\frac{1}{q}\nabla\overrightarrow{J_p} - \left(G^{\text{opt}} - R\right) = 0 \tag{36.3}$$

where R is the net electron–hole recombination rate, $\overrightarrow{J_n}$ the electron current density, and $\overrightarrow{J_p}$ is the hole current density.

Otherwise, *the drift-diffusion model* is widely used for the simulation of carrier transport in p-n junction photodiodes and is defined by the basic semiconductor equations, where current densities for electrons and holes are given by

$$\overrightarrow{J_\text{n}} = -nq\mu_\text{n}\nabla\phi_\text{n} \tag{36.4}$$

$$\overrightarrow{J_\text{p}} = -pq\mu_\text{p}\nabla\phi_\text{p} \tag{36.5}$$

where μ_n and μ_p are the electron and hole mobilities, ϕ_n and ϕ_p are the electron and hole quasi-Fermi potentials, respectively.

Additionally, *the thermodynamic model*, which is defined by a basic set of partial differential equations, and the lattice heat flow equations have been used in the simulations. The relations are generalized to include the temperature gradient as a driving term:

$$\overrightarrow{J_\text{n}} = -nq\mu_\text{n}\left(\nabla\phi_\text{n} + P_n\nabla T\right) \tag{36.6}$$

$$\overrightarrow{J_p} = -pq\mu_p\left(\nabla\phi_p + P_p\nabla T\right) \tag{36.7}$$

where P_n and P_p are the absolute thermoelectric powers.

36.3 Optical Generation Models

In the numerical simulation of the photoelectric detector, different structures and devices have different requirements for optical absorption models, including photoelectric incident position, power density, incident angle, reflection, refraction, and so on. Therefore, it is very important to select suitable optical

TABLE 36.1 Comparison of Some Common Optical Generation Models

generation models for different devices. The application conditions of some common optical generation models are listed in Table 36.1, and the characteristics of each model are introduced in this chapter.

Optical beam method is a simple optical absorption simulation method using Beer's law, and is only applicable to very simple optical process. Raytracing is capable of simulating a wide variety of optical effects such as reflection, refraction, and scattering, but its accuracy is severely limited, and cannot handle complex optical problems such as diffraction. Transfer matrix is very suitable for layered media, but requires media to be transversely isotropic. The FDTD method belongs in the general class of grid-based differential numerical modeling methods (finite difference methods). The time-dependent Maxwell's equations (in partial differential form) are discretized using central-difference approximations to the space and time partial derivatives, and could deal with more complex optical effects such as diffraction. Beam propagation method (BPM) is a quick and easy method of solving for fields in integrated optical devices, and a higher accuracy could be achieved. However, the BPM relies on the slowly varying envelope approximation, and is inaccurate for the modeling of discretely or fastly varying structures. What's more, BPM has some problems when dealing with scattering and diffraction problems.

36.3.1 Optical Beam Absorption

The optical beam absorption method supports the simulation of photogeneration using Beer's law. Multiple vertical photon beams can be defined to represent the incident light. The following equations describe useful relations for the photogeneration problem:

$$E_{\mathrm{ph}} = \frac{hc}{\lambda} \tag{36.8}$$

$$J_0 = \frac{P_0}{E_{\mathrm{ph}}} \tag{36.9}$$

where J_0 denotes the optical beam intensity (number of photons that cross an area of 1 cm^2 per 1 s) incident on the semiconductor device, P_0 is the incident wave power per area (W/cm^2), λ is the wavelength (cm), h is Planck's constant (J · s), c is the speed of light in a vacuum (cm/s), and E_{ph} is the photon energy that is approximately equal to $\frac{1.24}{\lambda\,(\mu\mathrm{m})}$ in eV.

The optical beam absorption model computes the optical generation rate along the z-axis taking into account that the absorption coefficient varies along the propagation direction of the beam according to

$$G^{\mathrm{opt}}(z,t) = J_0 F_t(t)\, F_{xy} \cdot \alpha(\lambda, z) \cdot \exp\left(-\left|\int_{z_0}^{z} \alpha(\lambda, z)\,\mathrm{d}z\right|\right) \tag{36.10}$$

where t is the time, $F_t(t)$ is the beam time behavior function: for a Gaussian pulse, it is equal to 1 for t in $[t_{\min}, t_{\max}]$ and shows a Gaussian distribution decay outside the interval with the standard deviation σ_t; F_{xy} is equal to 1 inside the illumination window and zero otherwise; z_0 is the coordinate of the semiconductor surface; and $\alpha(\lambda, z)$ is the nonuniform absorption coefficient along the z-axis.

The optical beam absorption method supports a wide range of window shapes as well as arbitrary beam time behavior functions. It is also not limited to beams propagating along the z-axis.

36.3.2 Raytracing

The optical generation method of raytracing supports the simulation of photogeneration in two dimensions (2Ds) and three dimensions (3Ds) for arbitrarily shaped structures. The calculation of refraction, transmission, and reflection follows geometric optics. A plane wave can be partitioned and each partition is represented by a 1D ray of light. Raytracing can approximate the behavior of a plane wave on a device by following such rays.

The optical generation along a ray, when the propagation is thought to be in the z-axis for a nonuniform absorption coefficient $\alpha(\lambda, x, y, z)$, can be written as a photon beam generation:

$$G^{\text{opt}}(z,t) = J\left(x,y,z_0\right)\alpha(\lambda,z)\cdot\exp\left(-\left|\int_{z_0}^{z}\alpha(\lambda,z)\,\mathrm{d}z\right|\right) \tag{36.11}$$

where $J(x, y, z_0)$ is the beam spatial variation of intensity over a window where rays enter the device, and z_0 is the position along the ray where absorption begins.

When a ray passes through a material boundary, the raytracer uses a recursive algorithm: It starts with a source ray and builds a binary tree that tracks the transmission and reflection of the ray. A reflection/transmission process occurs at interfaces with refractive index differences.

An incident ray impinges on the interface of two different refractive index (n_1 and n_2) regions, resulting in a reflected ray and a transmitted ray. The angles involved in raytracing are governed by Snell's law using

$$n_1\sin\left(\theta_1\right) = n_2\sin\left(\theta_2\right) \tag{36.12}$$

Absorption of photons occurs when there is an imaginary component (extinction coefficient), κ, to the complex refractive index. To convert the absorption coefficient to the necessary units, the following formula is used for power/intensity absorption:

$$\alpha(\lambda)\left[\text{cm}^{-1}\right] = \frac{4\pi\kappa}{\lambda} \tag{36.13}$$

In the complex refractive index model, the refractive index is defined element wise. In each element, the intensity of the ray is reduced by an exponential factor defined by $\exp(-\alpha L)$ where L is the length of the ray in the element. Therefore, the photon absorption rate in each element is

$$G^{\text{opt}}\left(x,y,z,t\right) = I\left(x,y,z\right)\left(1 - e^{(-\alpha L)}\right) \tag{36.14}$$

where $I(x, y, z)$ is the rate intensity of the ray in the element. After all of the photon absorptions in the elements have been computed, the values are interpolated onto the neighboring vertices and are divided by its sustaining volume to obtain the final absorption rate. The absorption of photons occurs in all materials with a positive extinction coefficient for raytracing. Depending on the quantum yield, a fraction of this value is added to the carrier continuity equation as a generation rate so that correct accounting of particles is maintained.

36.3.3 Transfer Matrix Method

The propagation of plane waves through layered media could be calculated by using a transfer matrix approach.

In the underlying model of the optical carrier generation rate, monochromatic plane waves with arbitrary angles of incidence and polarization states penetrating a number of planar, parallel layers are assumed. Each layer must be homogeneous, isotropic, and optically linear. In this case, the amplitudes of forward and backward running waves $A_j^{\pm}$ and $B_j^{\pm}$ in each layer shown in Figure 36.3 are calculated with the help of transfer matrices.

These matrices are functions of the complex wave impedances Z_j given by $Z_j = n_j \cdot \cos\theta_j$ in the case of E polarization (TE) and by $Z_j = n_j/\cos\theta_j$ in the case of H polarization (TM). Here, n_j denotes the complex index of refraction and θ_j is the complex counterpart of the angle of refraction ($n_0 \cdot \sin\theta_0 = n_j \cdot \sin\theta_j$).

The transfer matrix of the interface between layers j and $j + 1$ is defined by

$$T_{j,j+1} = \frac{1}{2Z_j} \cdot \begin{bmatrix} Z_j + Z_{j+1} & Z_j - Z_{j+1} \\ Z_j - Z_{j+1} & Z_j + Z_{j+1} \end{bmatrix} \tag{36.15}$$

The propagation of the plane waves through layer j can be described by the transfer matrix:

$$T_j\left(d_j\right) = \begin{bmatrix} \exp\left(2\pi i n_j \cos\theta_j \frac{d_j}{\lambda}\right) & 0 \\ 0 & \exp(-2\pi i n_j \cos\theta_j \frac{d_j}{\lambda}) \end{bmatrix} \tag{36.16}$$

with the thickness d_j of layer j, and the wavelength λ of the incident light. The transfer matrices connect the amplitudes shown in Figure 36.3 as follows:

$$\begin{bmatrix} B_j^+ \\ A_j^+ \end{bmatrix} = T_{j,j+1} \begin{bmatrix} A_{j+1}^- \\ B_{j+1}^- \end{bmatrix} \tag{36.17}$$

$$\begin{bmatrix} A_j^- \\ B_j^- \end{bmatrix} = T_j\left(d_j\right) \begin{bmatrix} B_j^+ \\ A_j^+ \end{bmatrix} \tag{36.18}$$

It is assumed that there is no backward running wave behind the layered medium, and the intensity of the incident radiation is known. Therefore, the amplitudes $A_j^{\pm}$ and $B_j^{\pm}$ at each interface can be calculated with appropriate products of transfer matrices.

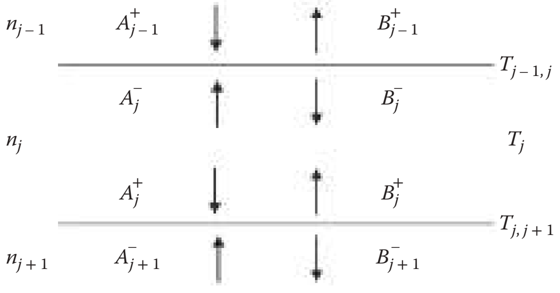

FIGURE 36.3 Wave amplitudes in a layered medium and transfer matrices connecting them.

For both cases of polarization, the intensity in layer j at a distance d from the upper interface $(j, j+1)$ is given by

$$I_{T(E,\mathrm{TM})}(d) = \frac{\Re(Z_j)}{\Re(Z_0)} \cdot \left\| T_j(d) \cdot \begin{pmatrix} A_j^- \\ B_j^- \end{pmatrix} \right\|^2 \tag{36.19}$$

with the proper wave impedances, $\Re(Z_j)$ means the real part of Z_j. If δ is the angle between the vector of the electric field and the plane of incidence, the intensities should be added according to

$$I(d) = aI_{\mathrm{TM}}(d) + I_{\mathrm{TE}}(d) \tag{36.20}$$

where $I_{\mathrm{TM}} = (1-a)I(d)$ and $I_{\mathrm{TE}} = aI(d)$ with $a = \cos^2\delta$.

36.3.4 FDTD Method

Light propagation through the sub-wavelength microstructure (such as nanoparticles, nanometal grating, photonic crystals, photo-trapping structures, and diffractive microlenses)-enhanced photodetectors is simulated by FDTD method based on a rigorous vector solution of Maxwell's equations. The computation area of the FDTD method is discretized into grid space where the electric field vector and the magnetic field vector are respectively arranged in the space and time step by 1/2, and the differential form of Maxwell's equations is rewritten as the central difference form with two-order accuracy.

In the calculation, these correspond to six time varying scalar equations in each Yee's grid (i.e., corresponding to the three spatial components of the electric and magnetic fields, as shown in Figure 36.4), along with the propagation of the electromagnetic field, the electromagnetic field is constantly updated in the set period until convergence. At this time, the corresponding electromagnetic field (light) has a stable distribution in the whole calculation area. At this point, the absorbed power density and the distribution of carrier density are calculated by assuming that each of the photons absorbed could excite an electron–hole pair.

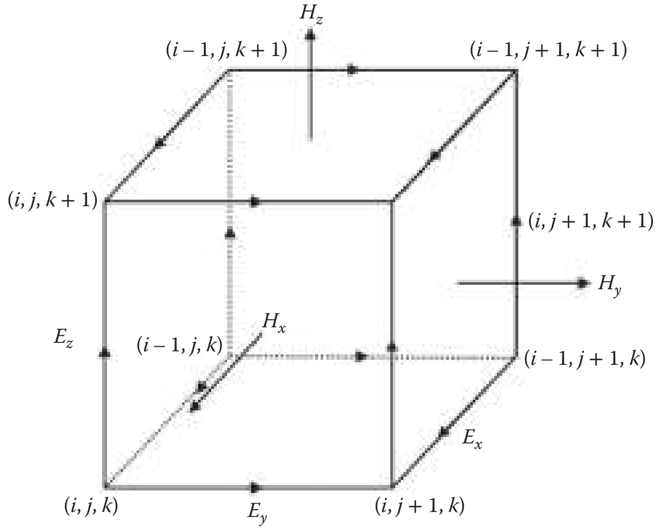

FIGURE 36.4 Structure of 3D Yee grid showing one cell of primary grid.

The differential forms of Maxwell equations are

$$\frac{\partial H}{\partial t} = -\frac{1}{\mu}\nabla \times E - \frac{\rho}{\mu}H \tag{36.21}$$

$$\frac{\partial E}{\partial t} = \frac{1}{\varepsilon}\nabla \times H - \frac{\sigma}{\varepsilon}E \tag{36.22}$$

Maxwell's curl equations can be discretized by the central difference method to achieve second-order accuracy. Equations 36.21 and 36.22 could be rewritten as formulas of electromagnetic field component:

$$\frac{\left.H_x\right|_{i,j,k}^{n+1/2} + \left.H_x\right|_{i,j,k}^{n-1/2}}{\Delta t} = \frac{1}{\mu_{i,j,k}}\left(\frac{\left.E_y\right|_{i,j,k+1/2}^{n} - \left.E_y\right|_{i,j,k-1/2}^{n}}{\Delta z} - \frac{\left.E_z\right|_{i,j+1/2,k}^{n} - \left.E_z\right|_{i,j-1/2,k}^{n}}{\Delta y} - \rho_{i,j,k}\cdot \left.H_x\right|_{i,j,k}^{n}\right) \tag{36.23}$$

$$\frac{\left.H_y\right|_{i,j,k}^{n+1/2} + \left.H_y\right|_{i,j,k}^{n-1/2}}{\Delta t} = \frac{1}{\mu_{i,j,k}}\left(\frac{\left.E_z\right|_{i+1/2,j,k}^{n} - \left.E_z\right|_{i-1/2,j,k}^{n}}{\Delta x} - \frac{\left.E_x\right|_{i,j,k+1/2}^{n} - \left.E_x\right|_{i,j,k-1/2}^{n}}{\Delta z} - \rho_{i,j,k}\cdot \left.H_y\right|_{i,j,k}^{n}\right) \tag{36.24}$$

$$\frac{\left.H_z\right|_{i,j,k}^{n+1/2} + \left.H_z\right|_{i,j,k}^{n-1/2}}{\Delta t} = \frac{1}{\mu_{i,j,k}}\left(\frac{\left.E_x\right|_{i,j+1/2,k}^{n} - \left.E_x\right|_{i,j-1/2,k}^{n}}{\Delta y} - \frac{\left.E_y\right|_{i+1/2,j,k}^{n} - \left.E_y\right|_{i-1/2,j,k}^{n}}{\Delta x} - \rho_{i,j,k}\cdot \left.H_z\right|_{i,j,k}^{n}\right) \tag{36.25}$$

$$\frac{\left.E_x\right|_{i,j,k}^{n+1} + \left.E_x\right|_{i,j,k}^{n}}{\Delta t} = \frac{1}{\varepsilon_{i,j,k}}\left(\frac{\left.H_z\right|_{i,j+1/2,k}^{n+1/2} - \left.H_z\right|_{i,j-1/2,k}^{n+1/2}}{\Delta y} - \frac{\left.H_y\right|_{i,j,k+1/2}^{n+1/2} - \left.H_y\right|_{i,j,k-1/2}^{n+1/2}}{\Delta z} - \sigma_{i,j,k}\cdot \left.E_x\right|_{i,j,k}^{n+1/2}\right) \tag{36.26}$$

$$\frac{\left.E_y\right|_{i,j,k}^{n+1} + \left.E_y\right|_{i,j,k}^{n}}{\Delta t} = \frac{1}{\varepsilon_{i,j,k}}\left(\frac{\left.H_x\right|_{i,j,k+1/2}^{n+1/2} - \left.H_x\right|_{i,j,k-1/2}^{n+1/2}}{\Delta z} - \frac{\left.H_z\right|_{i+1/2,j,k}^{n+1/2} - \left.H_z\right|_{i-1/2,j,k}^{n+1/2}}{\Delta x} - \sigma_{i,j,k}\cdot \left.E_y\right|_{i,j,k}^{n+1/2}\right) \tag{36.27}$$

$$\frac{\left.E_z\right|_{i,j,k}^{n+1} + \left.E_z\right|_{i,j,k}^{n}}{\Delta t} = \frac{1}{\varepsilon_{i,j,k}}\left(\frac{\left.H_y\right|_{i+1/2,j,k}^{n+1/2} - \left.H_y\right|_{i-1/2,j,k}^{n+1/2}}{\Delta x} - \frac{\left.H_x\right|_{i,j+1/2,k}^{n+1/2} - \left.H_x\right|_{i,j-1/2,k}^{n+1/2}}{\Delta y} - \sigma_{i,j,k}\cdot \left.E_z\right|_{i,j,k}^{n+1/2}\right) \tag{36.28}$$

Therefore, the electromagnetic field component can be solved by the Equations 36.23 through 36.28 for any given grid node at any moment.

For more detailed introduction of FDTD, see Chapter 52.

36.3.5 Beam Propagation Method

The BPM can be applied to find the light propagation and penetration into devices such as photodetectors. Its efficiency and relative accuracy are much better than the optical beam absorption method. The BPM solver is available for both 2D and 3D device geometries, where its computational efficiency compared with a full-wave approach becomes particularly apparent in 3Ds.

The BPM is based on the fast Fourier transform (FFT) and is a variant of the FFT BPM, which was developed by Feit and Fleck (1978).

The solution of the scalar Helmholtz equation is

$$\left[\nabla_t^2 + \frac{\partial^2}{\partial z^2} + k_0^2 n^2\left(x, y, z\right)\right] \phi\left(x, y, z\right) = 0 \tag{36.29}$$

At $z + \Delta z$ with $\nabla_t^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$ and $n(x, y, z)$ being the complex refractive index can be written as:

$$\frac{\partial}{\partial z}\phi\left(x, y, z + \Delta z\right) = \mp i\sqrt{k_0^2 n^2 + \nabla_t^2}\,\phi\left(x, y, z\right) = \pm i\xi\phi\left(x, y, z\right) \tag{36.30}$$

In the paraxial approximation, the operator ξ reduces to

$$\xi = \sqrt{k_0^2 n_0^2 + \nabla_t^2} + k_0\delta n \tag{36.31}$$

where n_0 is taken as a constant reference refractive index in every transverse plane. By expressing the field ϕ at z as a spatial Fourier decomposition of plane waves, the solution to Equation 36.29 for forward-propagating waves reads

$$\phi\left(x, y, z + \Delta z\right) = \frac{1}{(2\pi)^2}\exp\left(ik_0\delta n\Delta z\right)\int_{-\infty}^{+\infty} d\vec{k_t}\exp\left(i\vec{k_t}\cdot\vec{r}\right)\exp\left(i\sqrt{k_0^2 n_0^2 \to \vec{k}_t^2}\,\Delta z\right)\tilde{\phi}\left(\vec{k}_t, z\right) \tag{36.32}$$

where $\tilde{\phi}$ denotes the transverse spatial Fourier transform. As can be seen from Equation 36.32, each Fourier component experiences a phase shift, which represents the propagation in a medium characterized by the reference refractive index n_0. The phase-shifted Fourier wave is then inverse transformed and given an additional phase shift to account for the refractive index inhomogeneity at each $\left(x, y, z + \Delta z\right)$ position. In the numeric implementation of Equation 36.32, an FFT algorithm is used to compute the forward and inverse Fourier transform.

For more detailed introduction of BPM, see Chapter Chapter 4.

36.4 Characteristic Input Parameters

The basic physical mechanism involved in numerical simulations of p-n junction photodiodes is very complicated and, depending on devices and use environments, different material parameters should be chosen for appropriate physical models. Some are related to bandgap such as effective mass, and another part of the parameters contributes to noise such as all of the recombination rate, while the absorption coefficient is dominant for the light absorption properties of device. In addition, the minority carrier lifetime of each region significantly influence the carrier transport. This chapter introduces some typical material parameters and related physical models (Table 36.2).

36.4.1 Minority Carrier Lifetimes

The minority carrier lifetime refers to the average survival time of minority carriers, and can be calculated as:

$$\tau = \frac{\Delta n}{U} \tag{36.33}$$

where Δn is the nonequilibrium carrier concentration and U is the carrier recombination rate.

TABLE 36.2 Parameters That Can Be Specified from Parameter File

Parameters	Units
Room-temperature bandgap, E_g	eV
Dielectric constant, ε_r	1
Density of states in conduction band, N_C	cm^{-3}
Density of states in valance band, N_V	cm^{-3}
Electron mobility, μ_e	$cm^2/V \cdot s$
Hole mobility, μ_h	$cm^2/V \cdot s$
Electron saturation velocity, v_{Se}	cm/s
Hole saturation velocity, v_{Sh}	cm/s
Electron effective mass (relative), m_e	1
Hole effective mass (relative), m_h	1
Electron Auger coefficient, R_{Ae}	cm^6/s
Hole Auger coefficient, R_{Ah}	cm^6/s
Electron SRH lifetime, τ_{Se}	s
Hole SRH lifetime, τ_{Sh}	s
Radiative coefficient, R_R	cm^3/s
Absorption spectra, A_1	cm^{-1}
Absorption spectra, A_2	cm^{-1}
Absorption spectra, E_1	eV
Absorption spectra, E_2	eV
Absorption spectra, P	1

Note: SRH, Shockley–Read–Hall.

The electron concentration n_0 and the hole concentration p_0 under the thermal equilibrium state fit the function:

$$n_0 p_0 = n_i^2 \tag{36.34}$$

where n_i is the intrinsic carrier concentration.

The generation-recombination rate of radiative recombination model is given by

$$U_R = r(np - n_i^2) \tag{36.35}$$

where r is the electron–hole recombination probability and n, p are the electron and hole concentration, respectively. The minority carrier lifetime is given by

$$\tau = \frac{1}{r(n_0 + p_0 + \Delta p)} \tag{36.36}$$

To the SRH recombination model, the generation-recombination rate can be written as

$$U_{SRH} = \frac{N_t r_n r_p (np - n_i^2)}{r_n \left(n + n_1\right) + r_p (p + p_1)} \tag{36.37}$$

with

$$n_1 = n_0 \exp\left(\frac{E_t - E_f}{k_0 T}\right) \tag{36.38}$$

$$p_1 = p_0 \exp\left(-\frac{E_t - E_f}{k_0 T}\right) \tag{36.39}$$

where r_n and r_p are the capture coefficient of electron and hole, N_t is the concentration of recombination center, E_t is the recombination center energy level, E_f is the Fermi energy level, and T is the lattice temperature. The SRH minority carrier lifetime can be calculated by

$$\tau = \frac{r_n\left(n+n_1\right)+r_p(p+p_1)}{N_t r_n r_p(n_0+p_0+\Delta p)} \tag{36.40}$$

When the surface recombination model is considered, a revised formula is used based on the SRH recombination model:

$$U_{\text{Surf}} = \frac{s_n s_p(np-n_i^2)}{s_p\left(n+n_1\right)+s_n(p+p_1)} \tag{36.41}$$

where s_n and s_p are the surface recombination velocity of electron and hole.

The rate of Auger recombination is given by

$$U_A = (\gamma_n n+\gamma_p p)(np-n_i^2) \tag{36.42}$$

where γ_n and γ_p are the auger recombination coefficient of electron and hole. The Auger recombination minority carrier lifetime can be written by

$$\tau = \frac{1}{\left(n_0+p_0+\Delta p\right)\left(\gamma_n n+\gamma_p p\right)} \tag{36.43}$$

36.4.2 Interface Traps and Fixed Charges

The following expressions for trap concentration versus the energy (E) define different types of distributions:

$$\begin{array}{ll}
N_0 \text{ for } E = E_0 & \text{Single-energy level} \\
N_0 \text{ for } E_0-0.5E_s < E < E_0+0.5E_s & \text{Uniform distribution} \\
N_0\exp\left(-\left|\dfrac{E-E_0}{E_S}\right|\right) & \text{Exponential distribution} \\
N_0\exp\left[-\dfrac{(E-E_0)^2}{2E_S^2}\right] & \text{Gaussian distribution} \\
\begin{cases} N_0 & \text{for} \quad E = E_1 \\ N_2 & \text{for} \quad E = E_2 \\ \cdots & \qquad \cdots \\ N_m & \text{for} \quad E = E_m \end{cases} & \text{User-defined table distribution}
\end{array} \tag{36.44}$$

Trapped electron and hole concentrations on one energy level are related to occupation probabilities for electrons (r_n) and holes (r_p) as follows:

$$\begin{array}{ll} n_{Dt} = N_{Dt} r_n & n_t = N_{Et} r_n \\ p_{At} = N_{At} r_p & p_t = N_{Ht} r_p \end{array} \tag{36.45}$$

where n_{Dt} is the electron concentration of the donor trap level, p_{At} is the hole concentration of the acceptor trap level, n_t is the electron concentration of the neutral electron trap level, and p_t is the hole concentration of the neutral hole trap level, N_{Dt} is the donor trap concentration, N_{At} is the acceptor trap concentration,

N_{Et} is the neutral electron trap concentration, N_{Ht} is the neutral hole trap concentration. It's obvious that $r_{\mathrm{n}} = 1 - r_{\mathrm{p}}$.

In consideration of the presence of traps, the Poisson equation is revised:

$$\nabla\varepsilon \cdot \nabla\psi = -q\left(p - n + N_{\mathrm{D}^+} - N_{\mathrm{A}^-} + \sum_{E_{\mathrm{t}}} N_{\mathrm{Dt}} - n_{\mathrm{Dt}} - \sum_{E_{\mathrm{t}}} N_{\mathrm{At}} - p_{\mathrm{At}} + \sum_{E_{\mathrm{t}}} p_{\mathrm{t}} - \sum_{E_{\mathrm{t}}} n_{\mathrm{t}}\right) \tag{36.46}$$

where E_{t} means trap energy levels.

The balance of the carrier flow to and from a trap level gives the following expression for the electron concentration of the trap level:

$$\frac{\mathrm{d}n_{\mathrm{t}}}{\mathrm{d}t} = v_{\mathrm{th}}^{n}\sigma_{\mathrm{n}}\mathrm{N}_{\mathrm{Et}}\left[\frac{n_1}{g_{\mathrm{n}}}r_{\mathrm{n}} - n(1 - r_{\mathrm{n}})\right] + v_{\mathrm{th}}^{p}\sigma_{\mathrm{p}}\mathrm{N}_{\mathrm{Et}}\left[\frac{p_1}{g_{\mathrm{p}}}(1 - r_{\mathrm{n}}) - pr_{\mathrm{n}}\right] \tag{36.47}$$

where $v_{\mathrm{th}}^{\mathrm{n}}$ and $v_{\mathrm{th}}^{\mathrm{p}}$ are the electron and hole thermal velocities, σ_{n} and σ_{p} are the electron and hole capture cross sections, and g_{n} and g_{p} are the electron and hole degeneracy factors, respectively.

In the steady state, the trap-assisted recombination process can be analyzed by standard SRH recombination; however, to the transient case, the recombination processes for electrons and holes are different, and the SRH form cannot be applied. The differential equations for the electron-related occupation probability at each energy level are

$$\frac{\mathrm{d}r_{\mathrm{n}}}{\mathrm{d}t} + \left[v_{\mathrm{th}}^{\mathrm{n}}\sigma_{\mathrm{n}}\left(n + \frac{n_1}{g_{\mathrm{n}}}\right) + v_{\mathrm{th}}^{\mathrm{p}}\sigma_{\mathrm{p}}\left(p + \frac{p_1}{g_{\mathrm{p}}}\right)\right]r_{\mathrm{n}} = v_{\mathrm{th}}^{\mathrm{n}}\sigma_{\mathrm{n}}n + v_{\mathrm{th}}^{\mathrm{p}}\sigma_{\mathrm{p}}\frac{p_1}{g_{\mathrm{p}}} \tag{36.48}$$

This equation is solved self-consistently with the transport and Poisson equations.

The trap total recombination term in the continuity equations is the sum for all levels:

$$R_{\mathrm{trap}} = \sum_{E_{\mathrm{t}}} R_{\mathrm{Dt}} + \sum_{E_{\mathrm{t}}} R_{\mathrm{Et}} + \sum_{E_{\mathrm{t}}} R_{\mathrm{At}} + \sum_{E_{\mathrm{t}}} R_{\mathrm{Ht}} \tag{36.49}$$

At nonheterointerface vertices, bulk traps are considered only from the region with the lowest bandgap. In cases where the bulk traps from other regions are important, assume appropriate value and solve nonlinear Poisson equation by changing the numeric damping of the trap charge, which properly considers bulk traps from all adjacent regions.

36.4.3 Absorption Coefficients

A widely used absorption coefficient model that fits all the materials is

$$\alpha\left(E_{\mathrm{ph}}\right) = \begin{cases} \alpha_1 \exp\left[\dfrac{\left(E_{\mathrm{ph}} - E_1\right)}{E_2}\right] & E_{\mathrm{ph}} < E_1 \\ \alpha_1 + \alpha_2 \exp\left[\dfrac{\left(E_{\mathrm{ph}} - E_1\right)}{E_2}\right]^{p} & E_{\mathrm{ph}} \geq E_1 \end{cases} \tag{36.50}$$

where E_{ph} is the photon energy, and $\alpha_1, \alpha_2, E_1, E_2$, and p could be specified in the parameter file.

The abovementioned parameters can be obtained by fitting the data acquired in the experiment. A fitting result (Wang et al., 2015) for GaN and AlGaN are shown in Figures 36.5 and 36.6.

FIGURE 36.6 Fitting results of absorption spectrum for $Al_{0.15}Ga_{0.85}N$ at room temperature.

An absorption model (Rajkanan et al., 1979) is implemented for silicon and materials with similar bandgap structure:

$$\alpha(T) = \sum_{i=1}^{2}\sum_{j=1}^{2} C_i A_j \left\{ \frac{\left[hf - E_{gj}(T) + E_{pi}\right]^2}{e^{-\frac{E_{pi}}{kT}} - 1} + \frac{\left[hf - E_{gj}(T) - E_{pi}\right]^2}{1 - e^{-\frac{E_{pi}}{kT}}} \right\} + A_d \left[hf - E_{gd}(T)\right]^{1/2} \tag{36.51}$$

where

$$E_g(T) = E_g(0) - \frac{\beta T^2}{T + \gamma} \tag{36.52}$$

and T is the temperature. Parameter values used in this formula can be changed for some materials with bandgap structures similar to silicon or for silicon itself.

Instead, the complex refractive index model is adopted to replace the absorption coefficient model in some numerical simulation commercial software. The complex refractive index $\tilde{n}$ can be written as

$$\tilde{n} = n + i \cdot k \tag{36.53}$$

where n refers to the refractive index, and k to the extinction coefficient. The numerical conversion of the extinction coefficient k and the absorption coefficient α is

$$\alpha = \frac{4\pi k}{\lambda} \tag{36.54}$$

For specific extinction coefficients of different materials, one can refer to the website http://refractiveindex.info/.

36.5 Simulation Examples of P-N Junction Photodiodes

In the following section, examples of some widely used p-n junction photodiodes are introduced with the calculation results and parameters shown graphically. First, examples about visible photodiodes using different materials and structure are given. Second, photodiodes simulations applied to ultraviolet and infrared wave band are introduced. Finally, we modeled a two-color heterojunction photodiode, in which more complex mechanism and structure are included. All the absorption models involved in examples are based on Equation 36.50.

36.5.1 Physical Mechanism and Performance Parameters

In order to obtain comprehensive understanding of photoresponse (including dark current) mechanisms of p-n junction photodiodes and improve the device performance, these key parameters, such as electron field (when the effect of electric field intensity becomes dominant, the dark current will be increased and the photoresponse starts reducing); different kinds of junction types (see Figure 36.7a and b), which have a great effect on technological requirements, surface leakage current, and so on; dark current (see Figure 36.7c through f), which will influence our device performance; as well as responsivity and quantum efficiency (QE) should be taken into consideration. In addition, surface leakage current is another consideration of p-n junction photodiodes. A detailed description of the surface leakage current of HgCdTe infrared photodiode is shown in Figure 36.8.

The responsivity, quantum efficiency (QE) and cross-talk are index parameters measuring the ability of the device to acquire the target radiation signal. Responsivity is the light current formed by unit radiation power. The calculation formula is

$$R = \frac{I_0}{P_{\text{opt}}} \tag{36.55}$$

where R is the responsivity, I_0 is the optical current under zero bias, and P_{opt} is the power of incident light.

QE means the efficiency of the device with which the incident photons of light are converted to current:

$$\eta = \left(\frac{I_{\text{p}}}{q}\right)\left(\frac{P_{\text{opt}}}{hv}\right)^{-1} = \left(\frac{I_0}{P_{\text{opt}}}\right)hv = R\frac{1.24}{\lambda} = \frac{1.24R}{\lambda} \tag{36.56}$$

where λ is the wavelength of incident light and I_{p} is the light excitation current when the wavelength is λ (corresponding to the photon energy hv) and the power of incident light is P_{opt}.

Cross-talk is when the radiation signal in a unit produces a response signal R_0, the adjacent unit also appears in the response signal R_1. Cross-talk can be used to measure the image quality detection. The cross-talk is defined by:

$$C = \frac{R_1}{R_0} \times 100\% \tag{36.57}$$

36.5.2 Infrared Photodiodes

36.5.2.1 InP/In$_{0.53}$Ga$_{0.47}$As/InP PIN Photodiode

For an InP/In$_{0.53}$Ga$_{0.47}$As/InP PIN photodiode (Wang et al., 2008), the thickness of the absorption layer (T_{abs}) as a key structural parameter can determine, to a large extent, the magnitude of responsivity. The following discussion is concentrated on the effect of T_{abs} on the responsivity, and the following simulations are performed only at room temperature. Figure 36.9 shows the 2D structure of the device. The structure consists of a 0.5-μm heavily doped n-type InP buffer layer, a lightly doped n-type InGaAs absorption layer, and a 0.2-μm heavily doped p-type InP cap layer. The thickness of the InGaAs absorption layer (T_{abs}) is set as 1.5, 3.5, and 5.5 μm. Figure 36.10 presents the energy band of InP/InGaAs PIN device structure, respectively.

Here, the thickness of the InGaAs absorption layer is set as 1.5 μm. Vertical distributions of electric field with varying T_{abs} from 1.5 to 5.5 μm in 2-μm steps are investigated as shown in Figure 36.11; the dark and

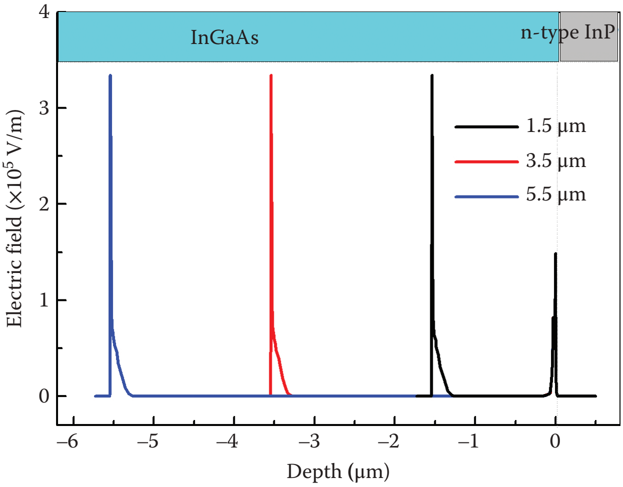

FIGURE 36.11 Vertical distributions of electric field with T_{abs} increasing from 1.5 to 5.5 μm in 2-μm steps.

light current characteristics with the absorption layer (T_{abs}) increasing from 1.5 to 5.5 μm in 1-μm steps are shown in Figure 36.12; the responsivity and QE, as a function of T_{abs} for different incident wavelengths, are shown in Figure 36.13. For clarity, the fitting parameters used in the simulation are listed in Table 36.3.

36.5.2.2 HgCdTe-Based P-N Junction Photodiode

Another example is the HgCdTe-based p-n junction photodiode infrared detector (Hu et al., 2008, 2010; Liang et al., 2014; Qiu and Hu, 2015; Yin et al., 2009; Wang et al., 2011a). The thickness of the n-region of the device has been chosen as a key structural parameter. This section discusses the effect of the thickness of the n-region on responsivity and QE of the device. The following simulations are performed at 77 K. Figure 36.14 presents a schematic diagram of the device where the white region represents the depletion region which is a space charge layer of a PN junction with positive charges in the n-type region and negative

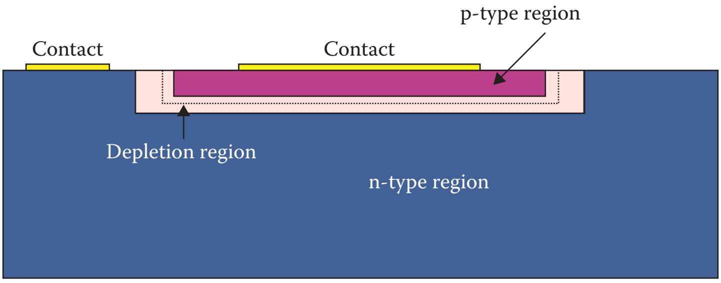

FIGURE 36.14 Schematic cross section of HgCdTe p-n junction photodiode.

charges in the p-type region. Figure 36.15 shows the energy band of the device with different thicknesses (d). Vertical distributions of electric field with the thickness of device (d) increasing from 3 to 7 in 2-μm steps under reverse bias of 200 mV are shown in Figure 36.16. Dark current and photocurrent with varying d from 3 to 7 μmin 2-μm steps under reverse bias are shown in Figure 36.17. The vertical distributions of the electric field of the device with three different conditions are very close. The responsivity and QE, as a function of d, for different incident wavelengths are shown in Figure 36.18. The responsivity and QE of the device with thickness of 5 μm are greater than those devices with thickness of 3 μm, because more photons can be absorbed by the material as the absorber region becomes thicker. However, the responsivity and QE of the device with thickness of 7 μm is smaller than that of the device with the thickness of 5 μm, because the recombination rate of the device with thickness of 7 μm increases, causing that photon-generated carriers to recombine before they arrive at the contacts. For clarity, the fitting parameters used in the simulations are listed in Table 36.4.

36.5.3 Visible Photodiodes

36.5.3.1 Si P-N Junction Photodiode

In the Si p-n junction photodiode, the influence of p-region thickness, operating temperature, and doping is calculated. Figures 36.19 and 36.20 show a schematic diagram and the energy band of a silicon p-n junction device structure, respectively. Vertical distributions of electric field with varying doping concentration are investigated as shown in Figure 36.21. Figure 36.22 shows the light and dark current distribution as a function of different operating temperatures. The responsivity and QE as a function of incident wavelengths for different p-region absorption layer are shown in Figure 36.23. Parameters not described are all according to those given as (default) in parameter Table 36.5.

36.5.4 Ultraviolet Photodiodes

36.5.4.1 GaN/AlGaN PIN Photodiode

The structure of a visible blind GaN/AlGaN PIN photodiode (Wang et al., 2011b, 2014) consists of three epitaxial layers grown on a 2-inch-diameter sapphire substrate. The first layer is a 0.6-µm n^+-doped AlGaN

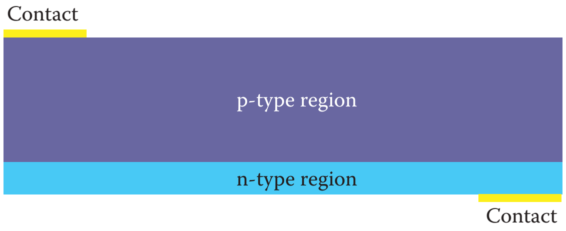

FIGURE 36.19 Schematic cross section of Si p-n junction photodetector.

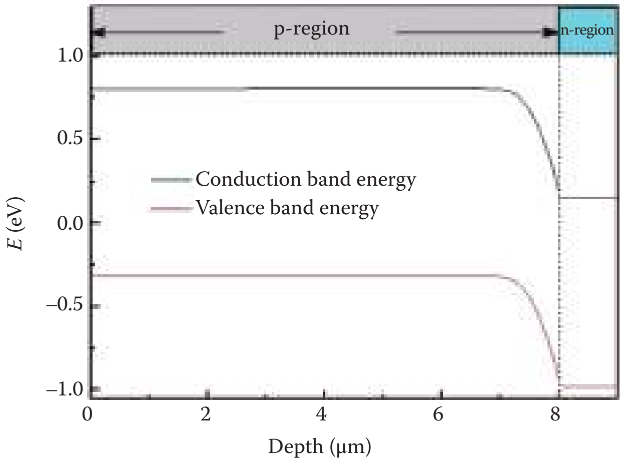

FIGURE 36.20 Energy band of Si p-n junction photodetector.

layer (n-layer) with a doping concentration of 3×10^{18} cm^{-3}. This layer is followed by a 0.1-μm unintentionally doped GaN absorption layer with an electron concentration of 5×10^{15} cm^{-3}, and a 0.15 μm p^{+}-doped GaN layer (p-layer) with a doping concentration of 3×10^{17} cm^{-3}. For simplicity, the thicknesses of the absorption layer and n-layer are defined as d_{abs} and d_{n}, respectively. The schematic cross section of

GaN/AlGaN PIN photodiode is shown in Figure 36.24. Figure 36.25 shows energy band as a function of vertical distance at equilibrium state, and the d_{abs} is set as 0.1 μm. Figure 36.26 describes responsivity versus the absorption layers (d_{abs}) with incident wavelengths of 0.30, 0.32, 0.34, and 0.36 μm, respectively, and electric field profile in the vertical direction with the absorption layers (d_{abs}) under 0.05, 0.2, 0.4, 0.6, and 0.8 μm.

The dark and light current characteristics with a bias voltage are shown in Figure 36.27. The absorption layer (d_{abs}) is set as 0.2 μm. Figure 36.28 shows responsivity and QE for GaN/AlGaN/GaN PIN photodiode with the absorption layer (d_{abs}) under 0.2, 0.3, 0.4, 0.6, and 1.1 μm. For clarity, the fitting parameters used in the simulation are listed in Table 36.6.

36.5.5 Two-Color Heterojunction Photodiodes

36.5.5.1 Long-Wavelength/Mid-Wavelength Two-Color HgCdTe

There are two important parameters for the long-wavelength/mid-wavelength (LW/MW) two-color HgCdTe infrared focal plane array detector (Hu et al., 2009, 2010, 2011, 2012, 2013, 2014; Qiu et al., 2016): (1) absorption layer thickness and (2) opening dimensions of the groove (the length of the groove top, L_{top}; the length of the groove bottom, L_{bot}). In the simulation, the electrical cross-talk of both LW to MW ($C_{\lambda e\text{-LW-to-MW}}$) and MW to LW ($C_{\lambda e\text{-MW-to-LW}}$) contributes to the total spectral cross-talk dependent on thickness and band energy offset of the barrier layer (as shown in Figure 36.29). Figure 36.30 shows the spectral photoresponse for the HgCdTe two-color infrared detector with the proposed structure from the previous numerical simulations. Figure 36.31 shows the QE and cross-talk as a function of the thickness of the MW layer for the grooved n_1^+-p_1-P-p_2-n_2^+ HgCdTe two-color infrared detector. It is found that a minimum MW-to-LW cross-talk and maximum MW QE can be achieved with an MW layer of approximately 7 μm. To further optimize the groove structure, the QEs with different L_{top} and L_{bot} are calculated at cutoff wavelengths. It indicates that the MW QE at the MW cutoff wavelength of 4.8 μm increases with L_{bot} (no

dependence on L_{top}). When $L_{\text{bot}} \geq 14$ μm, the MW QE saturates at a maximum value as the photogenerated carriers with the diffuse length of ~10 μm are efficiently collected by the MW contact. The specific details of the detector are listed in Table 36.7.

36.6 Summary

With the rapid development of computational capabilities and algorithm, numerical simulation becomes a very important tool in both qualitative and quantitative studies of p-n junction photodiodes. In this chapter, physical equations, models, and parameters that play important roles in the numerical simulation have been introduced. First, for the construction of basic theoretical framework, the well-known Poisson and continuity equations are introduced. Meanwhile, the widespread used drift-diffusion model and thermodynamic model is also described. The results show the effects of the important device parameters such as structure size, doping concentration, and incident wavelength on the device performance such as dark current, photoresponsivity, QE, and so on. Second, we introduced and compared the characteristics of several common optical generation models in detail, which could achieve optoelectronic simulations of different precision and structural requirements. Third, the characteristic input parameters and widely used models in the simulations of typical p-n junction photodiodes are discussed and introduced. Different input parameters and models can be selected according to different optoelectronic materials, device structure, and microscopic physical mechanism. Finally, we introduced some key parameters and measures of diode simulation, and simulation examples of some typical p-n junction photodiodes are given. In addition, some important results are numerically extracted, and the parameter tables used in the simulations are provided.

37.1 Introduction

Quantum well infrared photodetectors (QWIPs) are based on optical transitions among quantized states in the conduction band of the quantum wells (QWs). They are widely used in long-wavelength infrared (LWIR) detection such as in gas sensing (Hinnrichs and Guptab, 2008) and in Earth observation from space (Jhabvala et al., 2011). The popularity of QWIPs is gained from the advantages in material quality and uniformity, detector sensitivity and stability, and array availability and cost. Another unique advantage of this technology is its predictable optoelectronic properties. In the absence of the extrinsic effects imposed by impurities and surfaces, the observed photocurrent and dark current of a QWIP are intrinsic to the detector structure and are well understood from fundamental physics. More specifically, its dark current is found to agree with the familiar thermionic emission (TE) process, while the photocurrent can be quantitatively predicted from first principle calculations on QW energy levels and electromagnetic (EM) field distributions inside the detector volume. With the known dark and photocurrents, the detection characteristics and performance of a QWIP array placed in the focal plane of an optical lens system can readily be predicted with very few system parameters. But because of the arbitrariness of the QW materials and the detector geometries, the associated physical equations can only be solved by numerical means. In this chapter, we describe the theoretical framework and numerical modeling of QWIPs.

The role of photocurrent I_p and dark current I_d in affecting the sensitivity of a QWIP focal plane array (FPA) has been analyzed (Choi et al., 1998). Here, it suffices to note that while the signal S of a detector is directly proportional to I_p, the noise N is directly proportional to $(I_p + I_d)^{1/2}$, which can be derived from the Poisson statistics of charge collection. The signal-to-noise ratio of a QWIP is therefore proportional to

$$\left(\frac{S}{N}\right)_{\text{detector}} \propto \frac{I_{\text{p}}}{\sqrt{I_{\text{p}} + I_{\text{d}}}} = \left(\frac{I_{\text{p}}}{1 + I_{\text{d}}/I_{\text{p}}}\right)^{1/2} = \left(\frac{I_{\text{p}}}{1 + 1/r}\right)^{1/2}, \tag{37.1}$$

where r is the photocurrent to dark current ratio ($I_{\text{p}}/I_{\text{d}}$). From Equation 37.1, it is obvious that the S/N ratio is large only when I_{p} and r are large. In this chapter, we focus on the modeling of I_{p} and I_{d} in QWIP design and optimization.

37.2 Theoretical Model of QWIPs

A QWIP uses a multiple quantum well (MQW) structure to detect light (Levine et al., 1987). This structure is realized by growing alternate material layers of different bandgaps on a suitable substrate. The MQW creates a series of energy subbands, $E_1, E_2, \ldots$, in each QW unit. The QWs are doped n-type with a doping density N_{D} so that there are free electrons in the ground subband E_1 with a Fermi energy E_{F}. The band structure of a typical QWIP made of $\text{Al}_x\text{Ga}_{1-x}\text{As}/\text{In}_y\text{Ga}_{1-y}\text{As}$ is shown in Figure 37.1. In Figure 37.1, x is the aluminum mole fraction, y is the indium mole fraction, W is the well width, and B is the barrier thickness. An inter-subband absorption brings an electron from E_1 to E_n where the conductivity across the layers is higher. A photocurrent is thus created.

37.2.1 Dark Current

The dark current I_{d} of a QWIP can be qualitatively separated into three main components. They are direct tunneling (DI) between adjacent ground states, thermally assisted tunneling (TAT) near the top of the barrier, and TE over the barrier. These processes are indicated in Figure 37.2.

The TAT current originates from the finite thermal spreading of in-plane electron energy in E_1. Upon a scattering process, the in-plane energy combines with the out-of-plane energy, with which the electron tunnels more efficiently through the QW barrier. Therefore, the barrier transmission depends on the total energy rather than its energy components. Although each current component differs in details, such as the densities of initial and final states, the major factor in determining their magnitudes is the impedance of the QW barrier. By adopting an energy-dependent tunneling probability $\gamma(E, V)$ for the barrier, the total

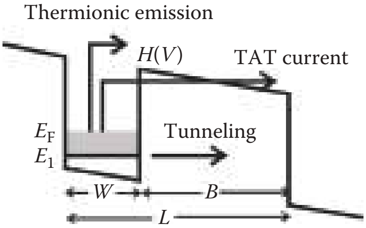

FIGURE 37.2 Different dark current transport processes in a QWIP. (TAT, thermally assisted tunneling.)

dark current can be obtained by summing over all electron energies (Levine et al., 1990):

$$\begin{aligned} J_d(V,T) &= \int_{E_1}^{\infty} e\rho_d(E,T)\, v_d(V)\mathrm{d}E, \\ &= \int_{E_1}^{\infty} e\left[\frac{g_{2D}}{L} f(E)\gamma(E,V)\right] v_d(V)\mathrm{d}E, \\ &= \int_{E_1}^{\infty} e\frac{m^*}{\pi\hbar^2 L}\frac{\gamma(E,V)\, v_d(V)}{1+\exp\left(\frac{E-E_F-E_1}{kT}\right)}\mathrm{d}E. \end{aligned} \tag{37.2}$$

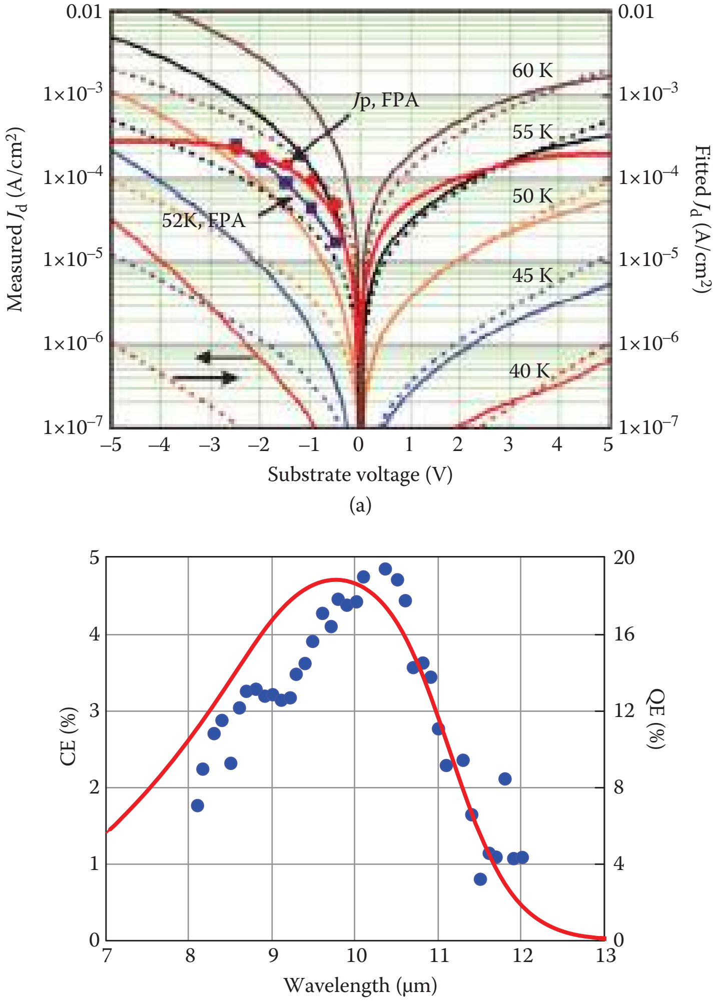
In Equation 37.2, $J_d(V,T)$ is the total dark current density under a bias of V per period at an operating temperature T, E the electron total energy, $\rho_d(E)$ the three-dimensional (3D) electron density per electron-volt, $v_d(V)$ the drift velocity, g_{2D} the 2D density of states, L the QW period length, $f(E)$ the Fermi–Dirac distribution, $\gamma(E,V)$ the tunneling probability of an electron with E under V, and m^* the electron effective mass in the well. The value of γ can be obtained from the usual Wentzel–Kramers–Brillouin (WKB) approximation (Choi, 1997) of a trapezoidal barrier with a barrier height H, a barrier thickness B, and an electron effective mass $m_b{}^*$ in the barrier. Specifically,

$$\begin{aligned} \gamma(E,V) &= \exp\left\{\frac{-4B}{3e\hbar V}(2m_b^*)\left[(H(V)-E)^{3/2}-(H(V)-eV-E)^{3/2}\right]\right\} \quad \text{for } E < H(V)-\text{eV}, \\ &= \exp\left\{\frac{-4B}{3e\hbar V}(2m_b^*)\,(H(V)-E)^{3/2}\right\} \quad \text{for } H(V) > E > H(V)-\text{eV}, \\ &= 1 \text{ for } E > H(V), \end{aligned} \tag{37.3}$$

where H is generally a function of V because there is a potential drop across the well as depicted in Figure 37.2, which depends on the W/L ratio. The drift velocity was experimentally found to be linearly proportional to the electric field (V/L) with a low-field mobility μ initially and then becomes saturated at a constant velocity v_{sat} when the field is high. Therefore, $v_d(V)$ can be represented as follows (Levine et al., 1990):

$$v_d(V) = \frac{\mu V/L}{\sqrt{1+\left(\mu V/Lv_{sat}\right)^2}}. \tag{37.4}$$

To fit the measured J_d, one can adjust H, μ, and v_{sat} in accounting for uncertainties in the material composition and quality.



(a)

(b)

FIGURE 37.3 (a) The measured J_d (solid curves), fitted J_d (dashed curves), and measured J_p (thick solid curves) of a test detector are shown. The symbols are measured from a focal plane array (FPA). (b) The predicted and measured quantum efficiency (QE) and conversion efficiency (CE) of the FPA at −3 V based on angled sidewall optical coupling are shown.

Figure 37.3 shows the typical current–voltage (I–V) characteristics of a QWIP. The substrate voltage refers to the bias applied on the substrate while the top contact is grounded. They are measured from a QWIP with a cutoff wavelength $\lambda_c = 11.2$ μm (Choi et al., 2011). The QWIP is made up of 60 periods of 700 Å $Al_{0.19}Ga_{0.81}As$ and 50 Å GaAs. The wells are doped with N_D of 1.7×10^{18} cm^{-3}. By adopting a constant $H = 191$ meV, $\mu = 400$ cm^2/V · s, and $v_{sat} = 1 \times 10^7$ cm/s, the dark current I–V characteristics under positive bias can be explained in a large range of temperatures. In this example, H is independent of V because the W/L ratio ($= 50/750 = 0.067$) is very small. The adopted H is consistent with the expected band offset from the barrier composition, and the values of μ and v_{sat} are nearly the same for all experimental LWIR detectors. This consistency shows that Equation 37.2 is a satisfactory dark current model for QWIPs. According to the symmetrical band structure shown in Figure 37.1, the I–V characteristics of a QWIP should be symmetric with respect to bias polarity. The higher measured dark current shown in Figure 37.3

under the negative bias is attributed to dopant migration during the material growth, which lowers the barrier height in the barrier region immediately after the doping.

37.2.2 Photoconductive Gain

The photocurrent I_p of a QWIP can be expressed as $I_\mathrm{p} = A\rho_\mathrm{p}ev_\mathrm{d}$, where A is the detector area, ρ_p the photoelectron density, and v_d the electron drift velocity. The parameter ρ_p can be further expressed as $G\tau/(A\ell)$, where G is the total photoelectron generation rate in the entire detector volume $A\ell$, ℓ the detector total thickness, and τ the average recombination lifetime of a photoelectron. After photoexcitation, a photoelectron only retains its energy in a period τ before it recombines into one of the QWs. Therefore, $G\tau/(A\ell)$ represents the time averaged photoelectron density. If we define the quantum efficiency (QE) η as the fraction of incident photon flux Φ being absorbed by the detector and converted into photoelectrons, the generation rate G will be $\eta\Phi$. Hence, I_p is given by

$$\begin{aligned} I_\mathrm{p} &= A\rho_\mathrm{p}ev_\mathrm{d}, \\ &= A\left(\frac{G\tau}{A\ell}\right)e\left(\frac{\ell}{\tau_\mathrm{tr}}\right) = \left(\frac{\eta\Phi\tau}{\ell}\right)e\left(\frac{\ell}{\tau_\mathrm{tr}}\right) = \eta\Phi\left(\frac{\tau}{\tau_\mathrm{tr}}\right)e, \\ &= \eta\Phi g e, \end{aligned} \tag{37.5}$$

where τ_tr is the time taken by a photoelectron to travel across the entire detector thickness ℓ, and $g = \tau/\tau_\mathrm{tr} = \tau v_\mathrm{d}/\ell$ is defined as the photoconductive gain. Equation 37.5 indicates that the measured number of photoelectrons (I_p/e) is g times the number of photons absorbed ($\eta\Phi$), resulted in a gain. Since the lifetime τ of a photoelectron is usually shorter than the transit time τ_tr in a QWIP, g is usually less than unity. Its photocurrent will then be lower than that of a photodiode with a gain of unity for the same QE. The value of g is usually deduced from noise measurements and theoretically fitted to the same functional form of v_d with τ as a fitting parameter. Experimentally, we found $\tau = 25$ ps for most LWIR QWIPs.

37.2.3 Photocurrent

Expanding the last line of Equation 37.5, the photocurrent is given by

$$\begin{aligned} I_\mathrm{p}(V, T_B) &= eg(V)\int_{\lambda_1}^{\lambda_2} \eta(V,\lambda)\Phi(T_B,\lambda)\mathrm{d}\lambda, \\ &= eg(V)\int_{\lambda_1}^{\lambda_2} \eta(V,\lambda)\Omega A L(T_B,\lambda)\mathrm{d}\lambda, \\ &= \frac{\pi}{4F^2+1}Aeg(V)\int_{\lambda_1}^{\lambda_2} \eta(V,\lambda)L(T_B,\lambda)\mathrm{d}\lambda. \end{aligned} \tag{37.6}$$

In Equation 37.6, Ω is the solid angle of the light cone sustained at the detector toward the lens. $L(T_\mathrm{B}, \lambda)$ is the photon spectral radiance of the scene, which has a unit of number of photons arrived per unit time per unit detector area per unit solid angle per unit wavelength. Expressing Ω in terms of the usual specification for a lens system, the f-number F, which is the ratio between the focal length f and the lens diameter D, $\Omega = \pi \sin^2(\theta) = \pi(D/2)^2/[f^2 + (D/2)^2] = \pi/(4F^2 + 1)$, where θ is the half-cone angle.

The parameter $g(V)$ is the photoconductive gain at V, λ_1 and λ_2 are the lower and upper wavelengths encompassing the detector absorption spectrum, and $\eta(V,\lambda)$ is the detection QE spectrum. $\eta(V,\lambda)$ can be decomposed into $\eta_{\text{abs}}(\lambda)\gamma(V)$, where η_{abs} is the fraction of incident photons being absorbed and $\gamma(V)$ is the tunneling probability of the photoelectron out of the barrier. For the typical QWIP designs, the upper subbands are above the barrier and thus $\gamma(V)$ is close to unity. Therefore, we usually assume $\eta(V,\lambda) \approx \eta_{\text{abs}}(\lambda)$, and label $\eta_{\text{abs}}(\lambda)$ simply as $\eta(\lambda)$ unless the effect of γ is apparent.

37.2.4 Absorption Coefficient

The magnitude of the photocurrent I_{p} in Equation 37.6 depends on the QE spectrum $\eta(\lambda)$. In QWIPs, the optical transitions are generated from the transition dipole moment between two envelope eigenfunctions in the z-direction. The optical electric field E of the radiation must be oriented in this direction to drive the transitions. When the optical field is polarized in the x–y plane, the dipole moment is zero due to conservation of momentum, and therefore, there is no absorption. Therefore, the optical absorption of the material depends on the direction of light propagation, and the absorption coefficient α is anisotropic. The parameter α is defined as $(-1/\Phi)(\mathrm{d}\Phi/\mathrm{d}x)$, where Φ is the photon flux and x is the traveling distance. In general, when the light is traveling at an angle θ relative to the normal of the layer surface, only the vertical electric component $E_z = E \cdot \sin(\theta)$ in the transverse magnetic (TM) mode is able to initiate the transitions. The transverse electric mode, on the other hand, is totally uncoupled. Therefore, for an unpolarized light, only half of its intensity is being absorbed, and α of the remaining half varies as $\sin^2\theta$. When θ is zero under the usual detection orientation, i.e., under normal incidence, α will be zero unless there is an optical coupling structure to convert the incident electric polarization from horizontal to vertical. Overall, $\eta(\lambda)$ of a QWIP depends on both the material intrinsic absorption properties and the detector physical structure.

For a parallel propagating light with vertical polarization, the absorption coefficient $\alpha(\hbar\omega)$ depends on the oscillator strength between the ground state and one of the upper states and the number of free carriers in the ground state. Quantitatively, $\alpha(\hbar\omega)$ is given by (Choi, 1997)

$$\alpha(\hbar\omega) = \frac{N_{\text{s}}}{L}\frac{\pi e^2 \hbar}{2m^* \sqrt{\varepsilon_{\text{r}}}\,\varepsilon_0 c}\sum_{n=2}^{\infty} f_n \rho_n(\hbar\omega + E_1), \tag{37.7}$$

where $N_{\text{s}} = N_{\text{D}}W$ is the 2D doping density per QW period, L the length of a QW period, m^* the effective electron mass of individual layers, ε_{r} the real part of the dielectric constant, f_n the oscillator strength between E_1 and E_n, and ρ_n the normalized density of states due to the presence of line broadening mechanisms. The oscillator strength f_n is given by

$$f_n = \frac{2\hbar^2}{m^*\left(E_n - E_1\right)}\left|\langle\psi_{\text{n}}\left|\frac{\partial}{\partial z}\right|\psi_1\rangle\right|^2, \tag{37.8}$$

where ψ_{n} is the eigenfunction of E_n. The overall absorption lineshape depends mostly on the energy distribution of E_n and the respective f_n with a weaker dependence on the individual ρ_n. We assume a Gaussian shape for ρ_n, i.e.,

$$\rho_n(E) = \frac{1}{\sqrt{2\pi}\sigma_{\text{n}}}\exp\left(-\frac{\left(E - E_n\right)^2}{2\sigma_{\text{n}}^2}\right), \tag{37.9}$$

where σ_{n} is the line broadening parameter. In the next section, we show modeling procedures for $\alpha(\hbar\omega)$.

37.3 Material Absorption Modeling

The eigenfunction ψ_n and eigenvalue E_n of an MQW can be obtained from the transfer matrix method (TMM) (Choi et al., 2002). In this method, ψ_j in the jth material layer is written as two counter-propagating plane wave states:

$$\psi_j = A_j\, e^{i\,k_j\,z} + B_j\, e^{-\,i\,k_j\,z}, \tag{37.10}$$

where A_j and B_j are two constants to be determined, and k_j is the wavevector given by

$$k_j(E) = \frac{\sqrt{2\,m_j^*(E)}}{\hbar}\sqrt{E - \Delta E_j}, \tag{37.11}$$

where $m_j^*(E)$ is the energy-dependent effective mass, E and ΔE_j are the electron energy and the conduction band offset measured from the GaAs conduction band edge, respectively. The constants A_j and B_j relate to A_{j+1} and B_{j+1} of the adjacent $(j+1)$th layer through the boundary conditions that both ψ and $(1/m^*)\mathrm{d}\psi/\mathrm{d}z$ are continuous across the interface:

$$\begin{aligned}\begin{bmatrix}A_j\\ B_j\end{bmatrix} &= \frac{1}{2}\begin{bmatrix}(1+\gamma_{j,j+1})\,e^{i\,(k_{j+1}-k_j)\,d_{j,j+1}} & (1-\gamma_{j,j+1})\,e^{-\,i\,(k_{j+1}+k_j)\,d_{j,j+1}}\\ (1-\gamma_{j,j+1})\,e^{i\,(k_{j+1}+k_j)\,d_{j,j+1}} & (1+\gamma_{j,j+1})\,e^{-\,i\,(k_{j+1}-k_j)\,d_{j,j+1}}\end{bmatrix}\begin{bmatrix}A_{j+1}\\ B_{j+1}\end{bmatrix}\\ &= \frac{1}{2}\,M_{j\,,j+1}\begin{bmatrix}A_{j+1}\\ B_{j+1}\end{bmatrix},\end{aligned} \tag{37.12}$$

where $\gamma_{j,j+1} = (m_j{}^*k_{j+1})/(m_{j+1}{}^*k_j)$ and $d_{j,j+1}$ is the spatial coordinate of the interface. The energy level structure of a multilayer material system can be obtained from the maxima of the global transmission coefficient T_G of a plane wave through the material. When the incident energy of the wave coincides with one of E_n's, strong resonant transmission occurs and T_G attains a local maximum. Assuming the plane wave incident from the left, the coefficients A_1 and B_1 for the first material layer on the left and the coefficients A_p and B_p of the last pth layer are connected by

$$\begin{bmatrix}A_1\\ B_1\end{bmatrix} = \frac{1}{2^{p-1}}\,M_{1,p}\begin{bmatrix}A_p\\ B_p\end{bmatrix}, \tag{37.13}$$

where $M_{1,p} = M_{1,2}M_{2,3}\ldots M_{p-1,p}$, and $M_{j,j+1}$ is defined in Equation 37.12. By assuming that there is no wave traveling to the left in the last period, one can set $A_p = 1$ and $B_p = 0$, with which all the coefficients in the layers are determined. The value of T_G at a given energy E is then equal to

$$T_\mathrm{G}(E) = \frac{1}{\left|A_1(E)\right|^2}\frac{v_p(E)}{v_1(E)} = \frac{2^{2p-2}}{\left|a_{11}(E)\right|^2}\frac{m_1^*(E)}{m_p^*(E)}\frac{k_p(E)}{k_1(E)}, \tag{37.14}$$

where v is the electron group velocity and a_{11} the first diagonal element of $M_{1,p}$. The local maxima in $T_\mathrm{G}(E)$ determine the locations of E_n. In general, these local maxima are less than unity unless the material structure is symmetrical. Calculating $A_\mathrm{n}(E)$ and $B_\mathrm{n}(E)$ at $E = E_n$ will yield ψ_n.

37.3.1 Material Parameters

The TMM calculation can be handled efficiently by a personal computer. The material parameters required for the InGaAs/AlGaAs material system had been collected and summarized (Shi and Goldys, 1999).

To begin with, the unstrained bandgap of the *i*th layer in the unit of meV is

$$E^u_{g,j} = 1424 + 1186\,x_j + 370\,x_j^2 - 1499\,y_j + 429\,y_j^2, \tag{37.15}$$

where x_j and y_j are the Al and In molar ratios in the *j*th layer, respectively. (In the present calculation, x and y both cannot be nonzero in a given layer, i.e., AlInGaAs quaternary compound is not considered.) Since the material layers are under strain, the values of bandgaps are modified. Assuming the strain is accommodated exclusively in the InGaAs well layers, which are usually much thinner than the GaAs/AlGaAs layers, the modified bandgap for $y_j > 0$ is

$$E^s_{g,j} = E^u_{g,j} + 2\,a\left(1 - \frac{c_{12}}{c_{11}}\right)\varepsilon_{11}, \tag{37.16}$$

where $a = -8700 + 2700y_j$ meV is the deformation potential, $c_{12}/c_{11} = (5.32 - 0.79y_j)/(11.81 - 3.48y_j)$ is the ratio of the elastic constants, and $\varepsilon_{11} = -0.405y_j/(5.6533 - 0.405y_j)$ is the hydrostatic component of the strain induced by the adjacent GaAs/AlGaAs material layers. Therefore, in the present assumption, the bandgap of InGaAs is widened while that of GaAs and AlGaAs are unchanged. The band offset ΔE_j is taken as

$$\begin{aligned} \Delta E_j &= \beta_x\,(E^u_{g,j} - 1424) \quad \text{if} \quad x_j > 0 \\ &= \beta_y\,(E^s_{g,j} - 1424) \quad \text{if} \quad y_j > 0, \end{aligned} \tag{37.17}$$

where β_x is the band offset parameter for the GaAs/AlGaAs interface and β_y is for the InGaAs/GaAs interface. From fitting detectors with different wavelengths, we notice that β_x increases from 0.60 to 0.77 when x decreases from 0.4 to 0.16, and β_y is 0.63 when $y < 0.34$. The effective mass at the conduction band edge is given by

$$m_j^* = 0.0665\,(1 + 1.256\,x_j - 0.579\,y_j). \tag{37.18}$$

Taking the band nonparabolicity into account, the effective mass $m_j{}^*(E)$ can be expressed in the form of

$$m_j^*(E) = m_j^*\left(1 + \frac{E - \Delta E_j}{E_{g,j}}\right), \tag{37.19}$$

where $E_{g,j}$ is the strain modified bandgap. With all these material parameters, the input parameters in Equation 37.14 are known. Since m^* varies from layer to layer, strictly speaking, Equations 37.7 and 37.8 need to be evaluated individually in each layer. For simplicity, we assume m^* to be the effective mass at the GaAs conduction edge since optical transitions mostly occur in the GaAs layers.

37.3.2 Numerical Examples

In this section, we present some examples and compare them to experiments. To measure the α lineshape, infrared (IR) light is incident on a 45° polished facet at the edge of a substrate (referred to as the edge coupling method), so that the optical electric field pointing at the z-direction is a factor of $1/\sqrt{2}$ of that of the TM component. The measured quantity is the responsivity (R) or the conversion efficiency ($CE \equiv \eta g$). The values of R and CE are related by

$$R(\lambda) = \frac{I_p}{P(\lambda)} = \frac{e\eta g\Phi(\lambda)}{\frac{hc}{\lambda}\Phi(\lambda)} = \frac{\lambda}{\frac{hc}{e}}\eta g = \frac{\lambda}{1.24\times 10^{-6}}CE(\lambda)\ \left[\frac{\mathrm{A}}{\mathrm{W}}\right], \tag{37.20}$$

where $P(\lambda)$ is the incident optical power. Since in the weak absorption limit, η is directly proportional to α (see Section 37.4.4 for details on this coupling scheme), we can compare either the experimental $CE(\lambda)$ lineshape to the theoretical $\alpha(\lambda)$ or $R(\lambda)$ lineshape to $\lambda\alpha(\lambda)$. In Figure 37.4, we show the calculated $f_n(\lambda)$ of a typical QWIP, labeled as Det. A, which is made of 21 periods of 500 Å $Al_{0.27}Ga_{0.73}As$/46 Å GaAs QWs. The TMM calculation was performed on a single QW unit. The result will be the same if the calculation is performed on the entire MQW when E_1 of individual wells are not coupled (Choi et al., 2002), and in this case, the total f is independent of B.

Substituting the f spectrum into Equation 37.7, $\alpha(\lambda)$ can be obtained. Figure 37.5 shows the calculated $\alpha(\lambda)$ for Det. A along with three other GaAs/AlGaAs detectors having different cutoff wavelength λ_c and doping density N_D. Figure 37.5 also shows the measured CE lineshape of each detector in arbitrary units. To fit the measurements, the values of β_x needs to vary from 0.665 to 0.715 for the nominal x from 0.27

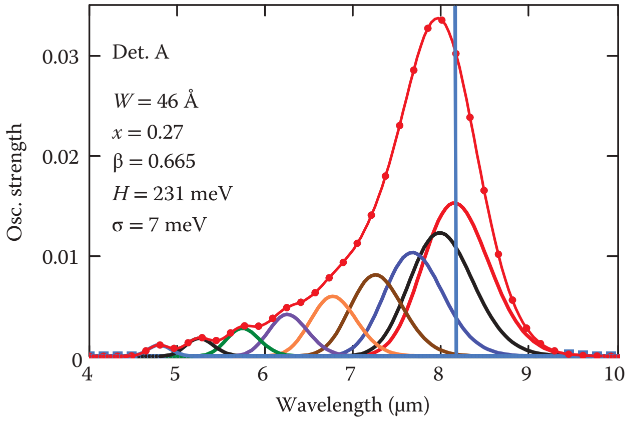


FIGURE 37.4 The calculated oscillator strengths f_n of a QWIP with $W = 46$ Å, $B = 500$ Å, $x = 0.27$, and $\sigma = 7$ meV. The curve with circles is the total oscillator strength. The vertical line shows λ at which the final state energy $= H - E_1$.

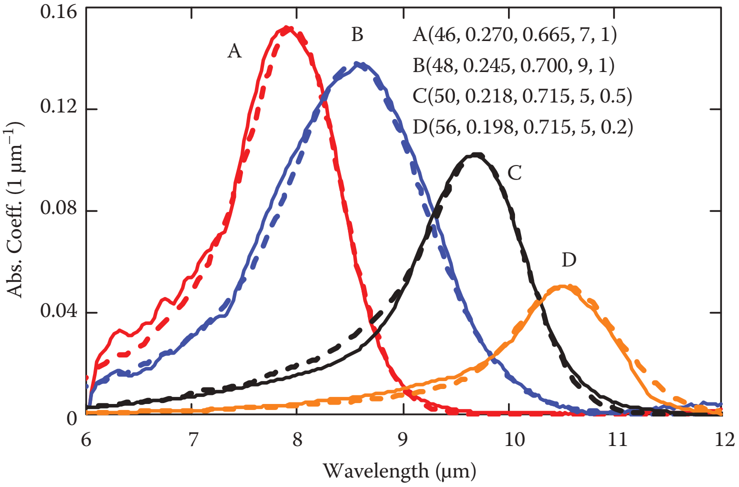

FIGURE 37.5 The measured CE lineshapes (solid curves) from four materials. The dashed curves are the calculated α assuming $(W, x, \beta_x, \sigma, N_D)$ shown in the figure, where N_D is in 10^{18} cm^{-3}. The barrier thickness is 500 Å for all detectors except 600 Å for Det. D.

to 0.198. The broadening parameter σ ranges from 5 to 9 meV for the first upper state, and it increases by about 0.5 meV for each successive upper state. With the two fitting parameters, β_x and σ, the intrinsic absorption lineshape can be satisfactorily explained.

The bandwidths shown in Figure 37.5 are rather limited. To broaden the bandwidth, one approach is to use superlattices (SLs) to create miniband-to-miniband (M–M) transitions. When the barrier thickness B is small, E_n states among different wells are coupled to form minibands M_n. Since the degenerate E_1 states develop into a range of occupied states in M_1, the absorption can cover a wider spectral range. This bandwidth can further be expanded if the QWs in the SL have different well widths (Choi et al., 2002).

To cover the entire 8- to 14-μm LWIR window, we designed a structure (Li et al., 2006) that contains seven SLs, and they are separated by 600-Å $Al_{0.17}Ga_{0.83}As$ barriers. Each SL contains seven 30-Å $Al_{0.23}Ga_{0.77}As$ barriers and four 70-Å and four 75-Å wells alternately placed together. The doping is 4×10^{17} cm^{-3} in the wells while the barriers are undoped. Since the eight miniband ground states within M_1 have different energies, their electron populations are also different. In this example, the first state in M_1 is at 39.4 meV and the last state is at 55.7 meV, while the common Fermi energy for the present doping is at 57.8 meV. Therefore, the electron population in the first state is 8.8 times larger than the last state, resulting in a significant modification of the lineshape from that of MQWs. Calculating Equation 37.7 with a different effective 3D doping density (N_s/L) for each miniband ground state according to the different Fermi levels, the spectral lineshape of the SL can be obtained. Figure 37.6 shows the calculated lineshape for the present SL. It agrees well with the measurement using a constant σ of 7 meV. The spectral responsivity is seen to cover the entire LWIR window. Following this material design approach, a QWIP with any cut-on and cutoff wavelengths can be designed.

By using InGaAs/AlGaAs QWs to increase the combined barrier height, a mid-wavelength IR QWIP can be developed (Choi et al., 2002). The illustrated structure contains eight $In_{0.34}Ga_{0.66}As/Al_{0.4}Ga_{0.6}As$ SL units separated by 500-Å $Al_{0.4}Ga_{0.6}As$ blocking barriers. Each unit consists of five wells and four barriers. The wells are made of 5-Å GaAs/25 Å InGaAs/5Å GaAs layers, and the barriers are made of 30-Å AlGaAs layers. There are top and bottom GaAs contact layers. All SL layers are doped to 2×10^{18} cm^{-3}. The modeled responsivity curve matches the experiment if $\sigma = 27.5$ meV as shown in Figure 37.7. This much larger σ is usually observed in the MWIR regime.

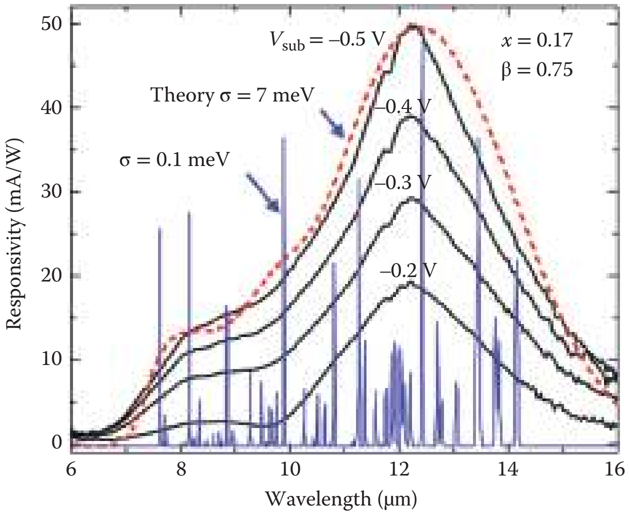

FIGURE 37.6 The measured responsivity from an SL structure with alternate well widths (solid curves). The fitted spectral lineshape of λα(λ) with σ = 7 meV is shown as the dashed curve. The curve with σ = 0.1 meV is to reveal the spectral distribution of individual M-M transitions.

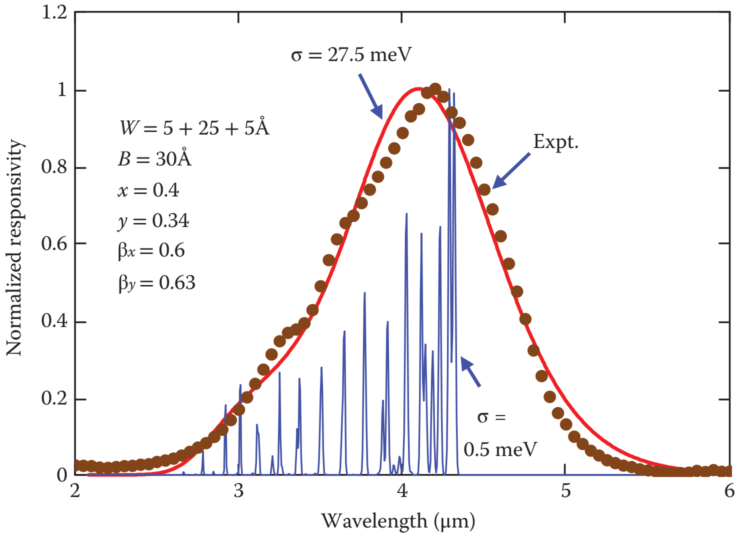

FIGURE 37.7 The measured normalized responsivity (circles) and the calculated $\lambda\alpha(\lambda)$ with $\sigma = 27.5$ meV (solid curve) for the combined transitions in the SL with blocking barriers. The curve with $\sigma = 0.5$ meV is to reveal the spectral distribution of individual M-M transitions.

37.4 Detector QE Modeling

Although $\alpha(\lambda)$ for parallel propagating light can be modeled accurately, the detector QE under normal incidence is still far from definite because it also depends on the optical coupling scheme. The search for an optimum coupling structure for a given application occupies the bulk of QWIP research to date. To yield the theoretical QE, one has to know the EM field distribution inside the detector volume in the presence of a polarization-dependent absorption coefficient. This task can only be solved by employing 3D numerical EM modeling. Since this capability was not readily available in the past, the common QWIP structures are not optimized.

With the advent of computer hardware and software technologies, one can now perform realistic and sophisticated EM modeling using commercial software on a personal computer. These advances have greatly facilitated the QWIP development. There are many numerical methods in solving EM problems. The more common ones are finite element method (FEM), finite-difference time-domain method, finite boundary method, and modal transmission-line (MTL) method, etc. In this chapter, we describe using FEM to model the theoretical QE of QWIPs.

FEM solves Maxwell's equation,

$$\nabla \times \left(\mu_r^{-1} \nabla \times \boldsymbol{E}\right) - k_0^2 \varepsilon_{rc} \boldsymbol{E} = 0, \tag{37.21}$$

via trial basis functions under a user-defined boundary condition. In Equation 37.21, μ_r and $\varepsilon_{rc} = \varepsilon_r - j\varepsilon_i$ are the relative permeability and relative permittivity, respectively, and $k_0 = 2\pi/\lambda$ is the free-space wavevector. Through variational principles, FEM transforms Equation 37.21 into a large set of linear equations, which can be solved by matrix multiplications (Sadiku, 2001). To yield a valid solution, it is important to present a correct boundary condition in the model.

The present modeling is performed in the RF Module of a commercial EM solver, COMSOL Multiphysics version 3.5 (COMSOL AB, Nov 2008). The modeling procedures involve selecting the EM analysis mode, building the 2D or 3D detector geometry, defining constants, variables, and functions, inputting subdomain properties, selecting appropriate boundary conditions, building mesh structures, setting solver parameters, performing computation, and using postprocessing to yield the required information.

To model the QE of a QWIP, we note that η can be expressed as (Choi et al., 2012, 2013a)

$$\begin{aligned}\eta(\lambda) &= \frac{1}{P_0}\int_V \mathrm{d}I(\mathbf{r}) = \frac{1}{P_0}\int_V \alpha(\lambda)I(\mathbf{r},\lambda)d^3r \\ &= \frac{\alpha(\lambda)}{A\frac{c\varepsilon_0}{2}E_0^2}\int_V \frac{n(\lambda)c\varepsilon_0}{2}\left|E_z(\mathbf{r},\lambda)\right|^2 d^3r = \frac{n(\lambda)\alpha(\lambda)}{AE_0^2}\int_V \left|E_z(\mathbf{r})\right|^2 d^3r, \qquad (37.22)\end{aligned}$$

where P_0 is the incident optical power, V the detector active volume, I the optical intensity associated with E_z, α the absorption coefficient, A the detector area, and n the material refractive index. Equation 37.22 states that the QE of a QWIP can be calculated from the volume integral of $|E_z|^2$ in the presence of a finite α. If E_z in Equation 37.22 is replaced by the total E, it will be applicable to detectors with isotropic absorption as well. Since E_0 and E_z are linearly proportional to each other, E_0 can be set arbitrarily. Besides E_0, the only free input parameter in Equation 37.22 is the wavelength-dependent $\alpha(\lambda)$ (if $n(\lambda)$ of the material is known accurately). For a known $\alpha(\lambda)$ from Equation 37.7, there will be no free parameters, and the value of $\eta(\lambda)$ for a given combination of material and geometry can be uniquely and unambiguously determined.

37.4.1 Modeling Validation and Phase Coherence

Since numerical EM modeling involves many steps, assumptions, and idealizations of materials and structures, it is critical to validate the model through theoretical and experimental means. One important assumption in the model is the complete phase coherence of radiation. While it is true for radio waves, it is generally not the case in the IR wavelengths and the rationale for EM modeling needs further explanation. If the optical field distribution in a detector indeed depends on the degree of coherence of light, the present modeling clearly will not be relevant. It follows that a QWIP will not have a definite QE, and its value depends on the light source characteristics. For a blackbody source, it is well known that the radiation is incoherent and its coherence length ℓ_c is only about $0.8\lambda_{\max}$, where $\lambda_{\max}$ is the free-space wavelength at the intensity maximum (Donges, 1998). At a blackbody temperature $T_B = 300$ K, $\lambda_{\max}$ is 10 μm, and ℓ_c is 8 μm in free space and 2.7 μm in GaAs. Such a short ℓ_c would suggest phase coherence exists only in a very small detector volume and coherent EM modeling would not be meaningful.

The abovementioned picture is certainly true when considering all of the radiations from the blackbody. Consistent with this picture, it also follows that the modeled coherent QE at $\lambda_{\max}$ will not be valid for all the blackbody radiations, which is also certainly the case. Nonetheless, when all the incoherent wave packets from the blackbody are Fourier transformed into the plane wave components, which happen to assume the Planck distribution, each individual wavelength component is in fact phase coherent. (By the definition of a plane wave with a definite λ, its coherence length is infinite.) Since the detector absorbs one photon with a definite λ at a time, not a wave packet with a broad spectrum at a time, the detector is interacting with each Fourier component individually, and because of this specific absorption feature, the spectrally dispersed radiation appears to be completely coherent to the detector at the individual wavelength component basis. Following this reasoning, there will only be one QE value for each λ, and it is the value evaluated under phase coherent condition. The modeled QE is thus an intrinsic property of the detector independent of the light source. Consequently, the detector maintains the same optical properties when detecting objects with different coherence lengths caused by, for example, different scene temperatures.

For experimental verification, when one of the Fourier components is separated out from a blackbody by an instrument, either using a grating or a filter, its coherence length $\ell_c = \lambda^2/\Delta\lambda$ becomes finite, where $\Delta\lambda$ is bandwidth of the instrument (Fowles, 1975). It is more convenient to use a light source with a long ℓ_c, i.e., a small $\Delta\lambda$, so that no QE convolution is need. However, even if $\Delta\lambda$ is substantial in comparison with the variation of modeled $\eta(\lambda)$, one can still make comparison by characterizing the spectral power density $P(\lambda)$ of the source around the nominal incident wavelength λ_0. The weighted theoretical $\eta(\lambda_0) = \int \eta(\lambda - \lambda_0)P(\lambda - \lambda_0)d\lambda / \int P(\lambda - \lambda_0)d\lambda$ can then be compared to experiment.

It is interesting to mention that when $\Delta\lambda$ of the instrument is broader than the detector absorption bandwidth Γ, the detector can only sense part of each wave packet emitted by the instrument, with which the coherence length appears to be longer at λ^2/Γ instead of $\lambda^2/\Delta\lambda$ for the original wave packet. Therefore, a detector with a given Γ will not be able to perceive the true phase coherence of a source if the source ℓ_c is shorter than λ^2/Γ. In the following, we present examples of modeling validation.

37.4.2 Planar Solar Cell

A planar GaAs solar cell provides a simple test for the modeling since it lacks any x–y spatial variations. Its material structure includes an active GaAs absorbing layer, a front antireflection coating, and a back metal reflector as shown in Figure 37.8 (Grandidier et al., 2012). With the known complex refractive indices of GaAs, and assuming 100% transmission for the antireflection (AR)-coating and 100% reflection for the reflector, a simple classical model for QE using ray-tracing technique is represented by the dash curve in Figure 37.9. On the other hand, using the complex refractive indices from all the constituent materials, the 2D modeling based on Equation 37.22 with isotropic absorption yields the solid curve. It coincides

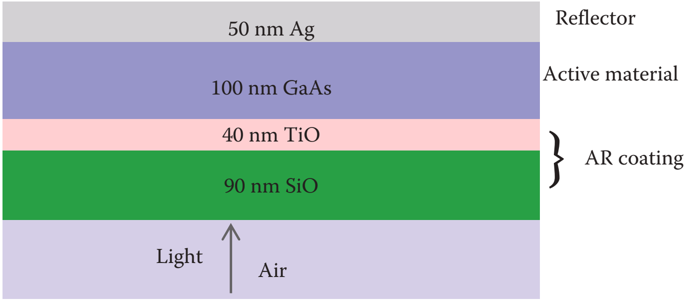

FIGURE 37.8 The modeled layer structure of a planar solar cell.

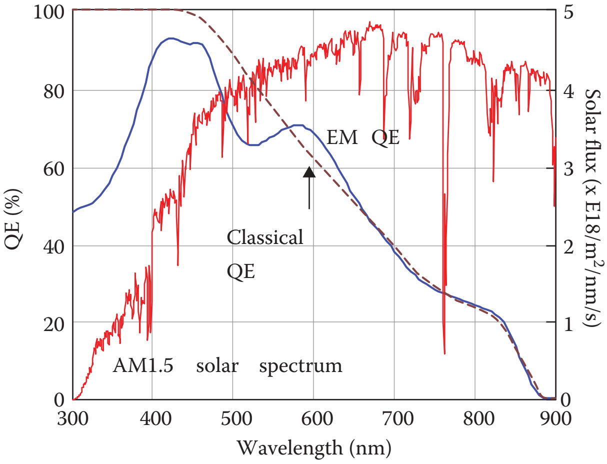

FIGURE 37.9 The quantum efficiency (QE) obtained by raytracing (dashed curve) and FEM (solid curve). The figure also shows the solar flux under 1-sun. (EM, electromagnetic.)

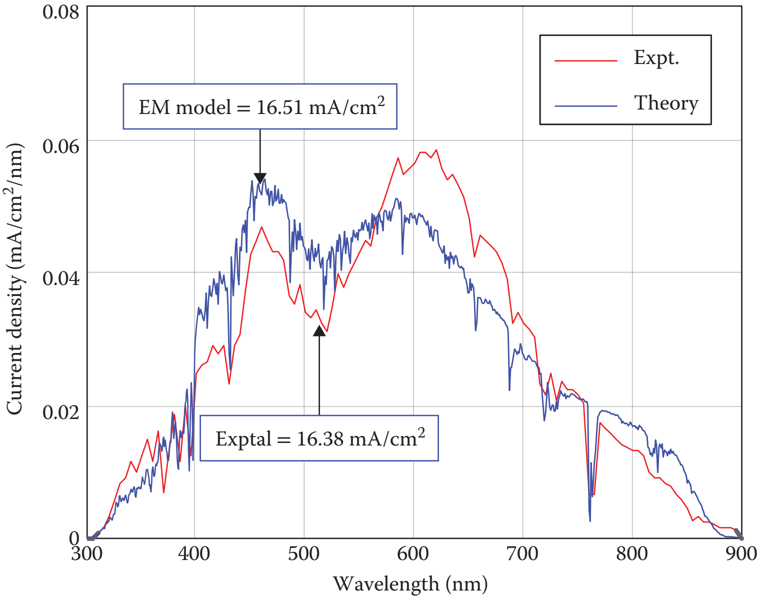

FIGURE 37.10 The measured and modeled photocurrent density under 1-sun without fitting parameters. (EM, electromagnetic.)

with the classical solution when the coatings in the modeling are effective. At the same time, the predicted photocurrent spectrum in Figure 37.10 is very similar to the measured spectrum (Grandidier et al., 2012) without any fitting parameters. In particular, the model accurately predicts two photocurrent peaks at 430 and 600 nm, which are absent in the simplified classical model. Furthermore, the model predicts the integrated photocurrent to be 16.51 mA/cm^2 under 1-sun condition, which is in excellent agreement with the measured 16.38 mA/cm^2. Therefore, without knowing the actual material properties in the experimental study, the agreement between theory and experiment is satisfactory for this device structure.

37.4.3 InAs/GaInSb IR Photodiode

When the detector material is fabricated into detector pixels, it acquires spatial variations. In this example, we show an IR photodiode in Figure 37.11 with a linear dimension of 22 μm in a 25-μm pitch array. It consists of a 2-μm thick p-InAs/Ga$_{0.75}$In$_{0.25}$Sb strained SL (p-SLS2) layer and a 0.5-μm thick wider bandgap n-SLS1 layer to form a photodiode. The photodiode is sandwiched between a 0.5-μm thick wider bandgap p-contact layer (p-SLS3) and a 2-μm thick n-InAs$_{0.9}$Sb$_{0.1}$ contact layer. On top of the p-contact, there is a 12-μm wide gold layer for ohmic contact. Light is incident from the n-contact layer. The detector is assumed to be surrounded by a semi-infinite epoxy material with $n = 1.5$ and with negligible IR absorption.

Since there is no AR-coating in this detector, Fabry–Pérot (FP) oscillations arise from optical interference between the top and bottom material interfaces. Because of the inhomogeneous phase change along the top surface, the FP oscillations are irregular. In Figure 37.12, we show the theoretical α spectrum of the p-SLS2 layer and the deduced α spectrum of n-InAs$_{0.9}$Sb$_{0.1}$ contact layer from open literature. The latter spectrum is obtained by shifting the experimental n-InAs spectrum by $\lambda = 0.7$ μm in accounting for the bandgap reduction (Miles et al., 1990). We further assume α of the n-SLS1 and p-SLS3 to be the same as that of p-SLS2 but at the shorter wavelengths (Dixon et al, 1961). The $n(\lambda)$ value in Equation 37.22 is taken to be a constant of 3.5, which is the average between 3.4 for InAs and 3.7 for GaSb at 10 μm. All IR absorption is assumed to be isotropic. Since the absorption of all the layers except the p-SLS2 layer will be dissipated as heat and no photocurrents will be generated in these layers, their absorption reduces the QE of the p-SLS2 layer in IR detection.

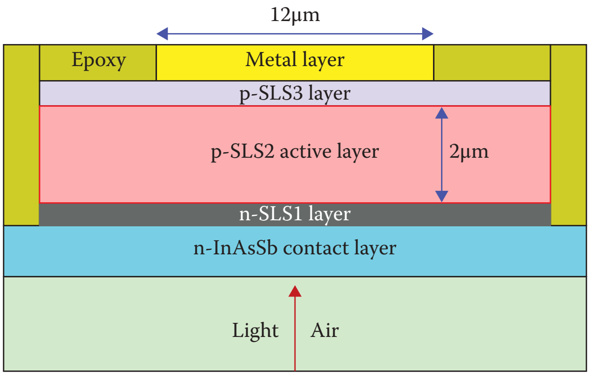

FIGURE 37.11 The material layer structure of a SLS photodiode. The pixel pitch is 25 μm.

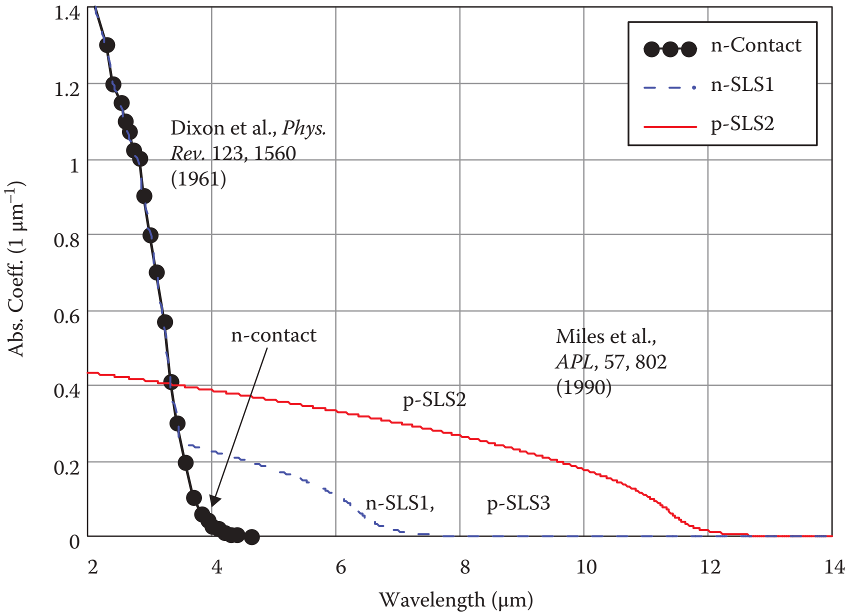

FIGURE 37.12 The theoretical and experimental α of individual layers obtained from open literature.

With these material and detector structures, the detector QE spectrum is modeled and the result is shown in Figure 37.13. Without adjusting any input parameters, the theoretical prediction matches satisfactorily with the experiment both in magnitude and in spectral lineshape in the entire spectral range. This example shows the validity of the modeling in the presence of spatial variations.

37.4.4 Edge Coupling for QWIPs

In Section 37.3.2, we assumed optical coupling efficiency using a 45° facet to be λ-independent in order to employ this coupling scheme for material characterization. It is worth checking its validity (Choi et al., 2012). Figure 37.14 shows the detector geometry and the calculated E fields with $E_0 = 377$ V/m. The detector has a 3-μm thick active QWIP layer, a 1-μm top contact layer, and a 1-μm gold layer. The detector is 100-μm wide. The value of α is assumed to be 0.15 μm^{-1}, and it is λ independent.

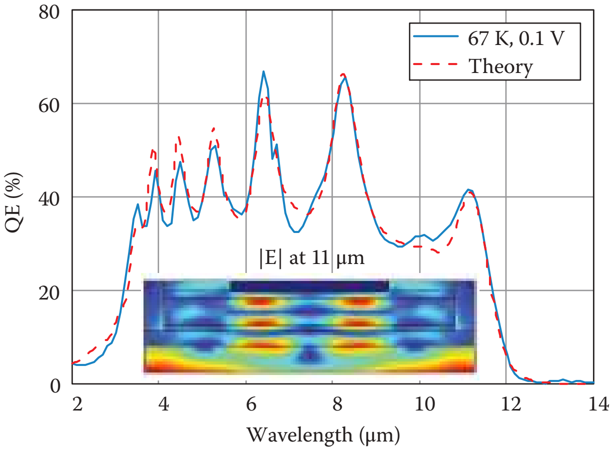

FIGURE 37.13 The calculated and the measured quantum efficiency (QE) of the p-SLS2 layer. The experimental data are provided by M. Jhabvala at NASA Goddard Space Flight Center. The insert shows the color plot of the |*E*| distribution at λ = 11 μm.

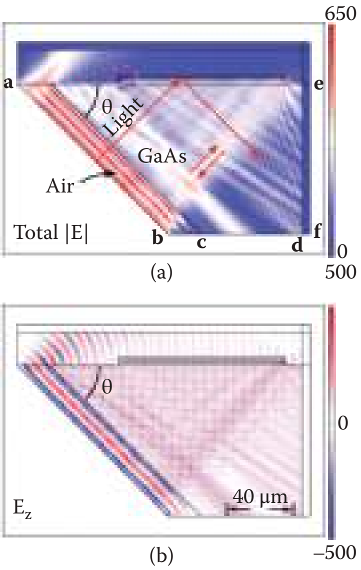

FIGURE 37.14 (a) The detector geometry at wedge angle θ of 45°. The arrows show the typical light paths. (b) The corresponding E_z is shown.

The 2D modeling with anisotropic absorption shows that QE at θ = 45° as well as other angles are nearly independent of λ as shown in Figure 37.15, justifying the experimental approach. The small oscillations are due to FP oscillations established in one of the detector corners shown in Figure 37.14a, but they will not be noticeable in the presence of edge roughness. In Figure 37.15, we also show the classical QE calculated from

$$\eta_c(\theta) = \frac{4n}{(1+n)^2}\frac{\cos\theta}{2}\left[1-\exp\left(-\alpha\sin^2\theta\cdot\frac{2\ell}{\cos\theta}\right)\right], \tag{37.23}$$

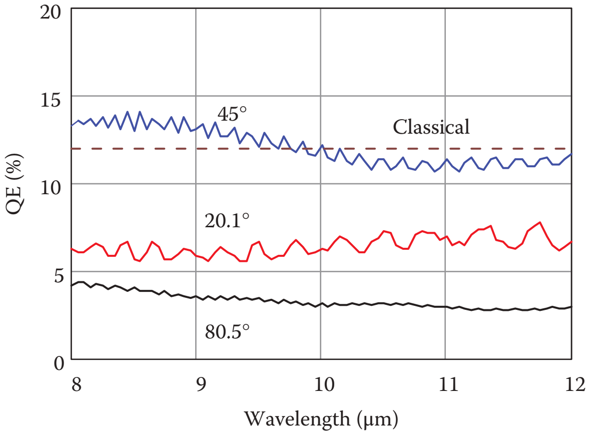

FIGURE 37.15 The calculated quantum efficiencies (QEs) at three different wedge angles. The dashed lines show the classical value at θ = 45°.

where $\ell = 3$ μm is the active layer thickness and $\theta = 45°$ is the angle of the polished wedge, which is also the angle of incidence measured from the detector normal. In Equation 37.23, $4n/(1+n)^2$ is the transmission coefficient of the GaAs substrate. The term $\cos(\theta)/2$ accounts for the smaller projected detector area in the direction of light and the fact that only the TM mode is coupled. The factor $\alpha \cdot \sin^2(\theta)$ is the absorption coefficient under oblique incidence, and $2\ell/\cos(\theta)$ is the total optical path length inside the detector accounting for the internal reflection at the top of the detector. In this classical model, if α is constant respect to the wavelength, η_c will also be wavelength independent. In Figure 37.15, η_c is shown to agree with the mean value from EM modeling. Therefore, EM modeling indeed supports the edge coupling approach in material characterization.

37.4.5 Quantum Grid Infrared Photodetector

Equipped with a quantitative model, we can revisit some of the QWIP coupling structures used in the past. Figure 37.16a shows the cross section of a structure known as the quantum grid infrared photodetector (QGIP) (Choi et al., 2004). It uses a metal layer on top of long and linear grid lines to scatter light incident from the bottom. The width w of the grid line acts as a half-wave dipole antenna and its dimension determines the detection wavelength. This detector geometry can also be modeled by 2D MTL method (Tamir and Zhang, 1996). Figure 37.16b compares the MTL solution and the present FEM solution for the same QGIP structure, assuming the same constant ε_i of $9.722 + i$. The close agreement in the QE spectrum between these two methods and the agreement between the methods and the experiment (Choi et al., 2004; not shown here) confirm the validity of both EM models. The E_z field distribution under the individual metal grid lines shows the expected scattering pattern from a dipole antenna.

37.4.6 Plasmonic-Enhanced QWIP

The structures described earlier were modeled in 2D. In this example, we perform 3D modeling as the structure cannot be reduced to 2D. The present structure, shown in Figure 37.17, uses surface plasmon to couple incident light into a QWIP (Wu et al., 2010). Surface plasmon is the resonant oscillation of conduction electrons at the interface between a metal and a semiconductor under optical excitation. The detector in this case contains a 400-Å thick gold film deposited on a 0.528-μm-thick InGaAs/InP active material.

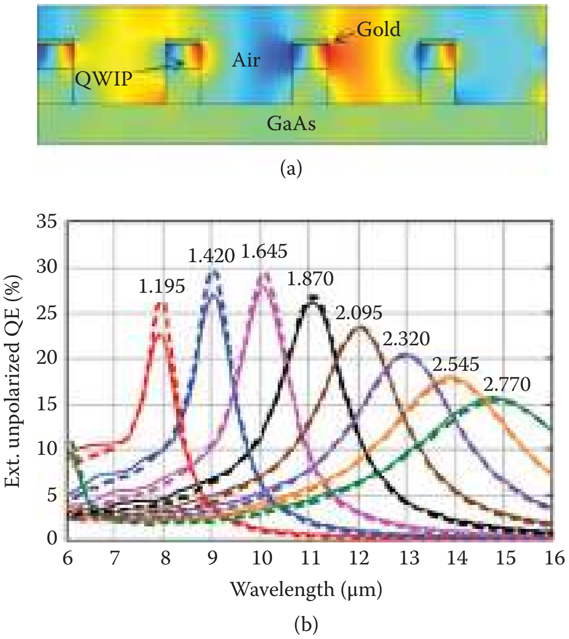

FIGURE 37.16 (a) The QGIP structure and the E_z distribution for $w = 1.87$ μm and $\lambda = 11.1$ μm. (b) The quantum efficiency (QE) spectra calculated based on FEM (solid curves) and MTL (dashed curves) having the same detector parameters. The numbers are w in microns. (QWIP, quantum well infrared photodetectors.)

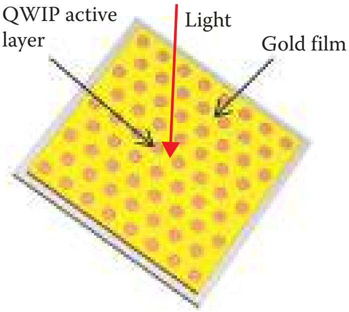

FIGURE 37.17 The 3D perspective of a plasmonic-enhanced quantum well infrared photodetectors (QWIP). Light is shining through the perforated gold layer from the top.

The gold layer is perforated with circular holes in a hexagonal lattice with spacing of 2.9 μm, and the hole diameter is 1.4 μm. The light incident on the gold layer excites surface plasmons in the opposite side with a resonant wavelength determined by the hole pattern. The resonant surface plasmons then create an intense vertical field at the gold/semiconductor interface. The active material has a low doping, with which the peak α is calculated to be 0.05 μm^{-1}. The modeled QE assuming this constant α for E_z is shown in Figure 37.18. It has a narrow peak at $\lambda = 8.3$ μm. Meanwhile, from the measured responsivity spectrum (Wu et al., 2010) and the estimated gain of 8.5 from a similar detector structure (Eker et al., 2010), the experimental peak QE is deduced to be 12.6%, which agrees with the modeling to within 10%, and the two spectra have similar lineshapes.

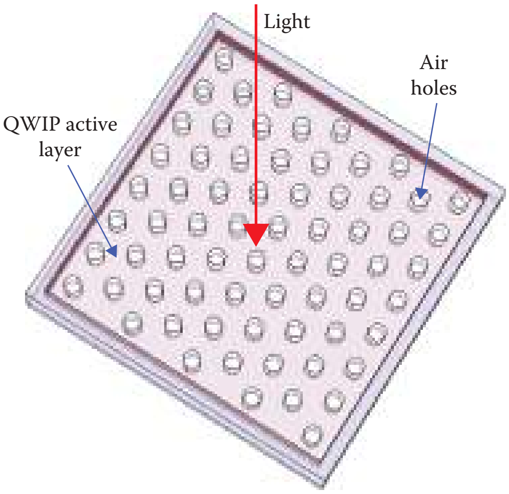

FIGURE 37.19 The 3D perspective of the PCS-QWIP. (QWIP, quantum well infrared photodetectors.)

37.4.7 Photonic Crystal Slab QWIP

To show another 3D optical structure, Figure 37.19 shows a photonic crystal slab QWIP (PCS-QWIP) studied (Kalchmair et al., 2011). The PCS is made of QWIP material, which is filled with periodic holes. These holes create a periodic modulation of refractive index in the x- and y-directions. Together with refractive index difference between GaAs and air in the z-direction, the PCS creates a series of characteristic photonic bands and bandgaps for the parallel propagating light. The normal incident light excites the stationary photonic eigenstates at the Γ-point of these bands in strong and sharp resonances. The present detector consists of an array of holes with spacing of 3.1 μm and diameter of 1.24 μm etched through the active and bottom contact layers. There is no metal layer in the optical path. The active material thickness is 1.5 μm, and the bottom contact thickness is 0.5 μm. The PCS is suspended in the air at a height t_{air} of 2.0 μm above the GaAs substrate.

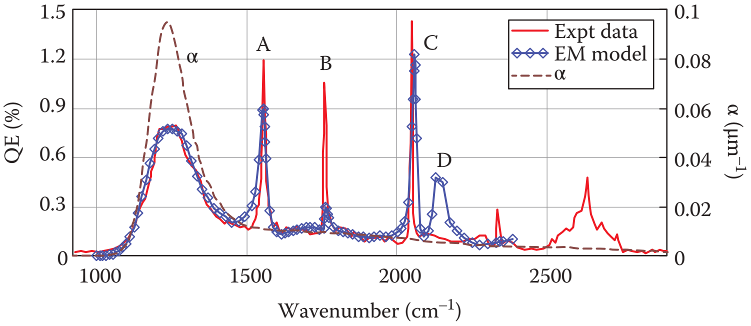

FIGURE 37.20 The measured photocurrent spectrum in arbitrary unit (solid curve) and the calculated QE spectrum based on the displayed α spectrum. (EM, electromagnetic.)

The measured photocurrent spectrum is shown in Figure 37.20. Based on the material α spectrum shown in Figure 37.20, which is deduced from the edge-coupled detector, the QE spectrum is modeled and it indeed contains the characteristic sharp peaks. However, the calculated peaks do not align exactly with the measurement. To obtain a better alignment, the theoretical hole spacing is reduced slightly from 3.1 to 2.9 μm as shown in Figure 37.20. This discrepancy could be due to the assumption of an average GaAs refractive index n to be 3.239 over a wide range of wavelengths. In reality, the value of n varies from 3.34 at 4 μm to 3.04 at 11 μm. Furthermore, the magnitudes of these peaks depend weakly on t_{air}. To obtain a larger peak at position B in Figure 37.20, t_{air} is adjusted from 2.0 to 0.9 μm. A different t_{air} could be due to the sagging of the PCS in the air at the operating temperature. From the modeling, the sharpness of these peaks is caused by two factors. One is the nearly symmetrical detector structure, both in vertical and horizontal directions, which induces strong resonances. The second is the weak material absorption at the peak wavelengths, which introduces only small damping effects on the resonances. The close match of the main peak and some of the side peaks lends support to the present modeling approach.

The large responsivity peaks A to C in the absorption tail illustrate that a large relative photoresponse can be obtained by using resonance in spite of a small intrinsic material absorption. Besides the examples presented earlier, we have also modeled other coupling structures, and the agreements between theory and experiment are similar to those presented (Choi et al., 2013a). They include air resonant cavities, linear and cross gratings, random-gratings, corrugated-QWIPs (C-QWIPs), etc. After studying all these examples, we found that the present FEM is highly accurate when comparing with other theoretical models. It also agrees well with experiments in both magnitudes and spectral lineshapes when both modeling and experimental uncertainties are taken into account.

37.5 EM Design of Resonator-QWIPs

The present FEM solves Maxwell equations numerically and thus should be able to optimize any detectors mentioned earlier as well as exploring new ideas. Among the many possible mechanisms and geometries, one structure that can yield a large QE is a photon trap. The function of a photon trap is to capture and hold incident light inside the detector until it is absorbed by the detector.

37.5.1 Resonator-QWIP Design

One realization of a photon trap is the resonator-QWIP (R-QWIP) as shown in Figure 37.21 (Choi et al., 2013a). It consists of an active layer, a thin GaAs substrate layer, and a number of diffractive elements (DEs) made of the same GaAs material on top. The topmost surface is then covered with a metal layer, and the detector is encapsulated with a low refractive index material.

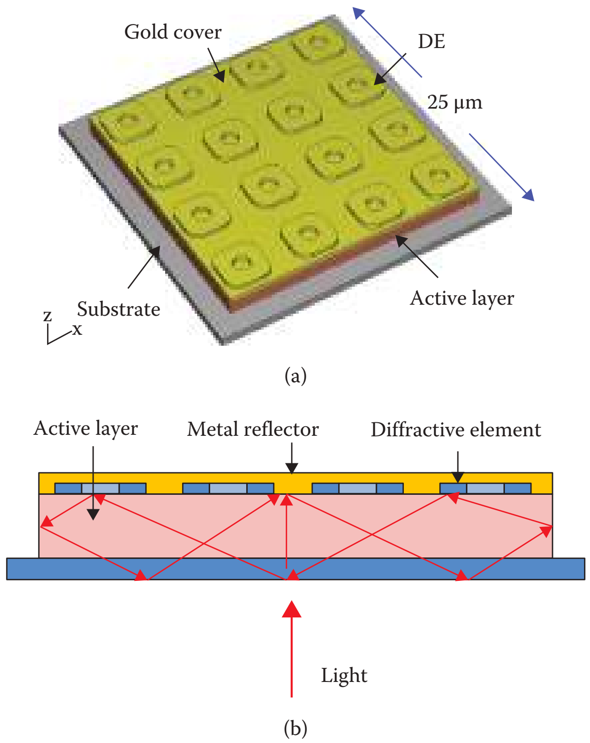

FIGURE 37.21 (a) A 3D perspective of an R-QWIP. Light is incident from the bottom. (b) The cross-section and one possible optical path.

The function of the DEs is to diffract incident light such that the subsequent angles of incidence at all detector boundaries are larger than the critical angle for total internal reflection (~18° for GaAs/air interface). If this is the case, the light will be totally confined in the detector. To account for interference effects, the size and shape of the detector volume are adjusted such that the scattered optical paths form a constructive interference pattern inside the detector. Under this condition, the newly incident light will be able to reinforce the light already under circulation, and the optical energy can be accumulated and stored in the detector as in a resonator. Therefore, by designing the detector into a resonator with a diffractive surface, i.e., an R-QWIP structure, an effective photon trap can be obtained.

To demonstrate the light storage capability, we first set α to zero so that there is no optical absorption in the detector. We then adjust the detector dimensions such that the intensity enhancement ratio (r_{ie}) given by

$$r_{ie} = \frac{1}{\frac{c\varepsilon_0}{2}E_0^2}\frac{nc\varepsilon_0}{2}\frac{1}{V}\int_V |E|^2 d^3r \tag{37.24}$$

reaches a maximum. The detector dimensions include the shape, size, and spacing of the DEs, the DE distribution pattern, the material layer thicknesses, the detector areal dimensions, etc. The quantity r_{ie} compares the average intensity built up inside the active volume relative to the incident intensity in the air. Figure 37.22 shows that r_{ie} can attain a value of 20 at 9.6 μm with the optimized structure shown in Figure 37.21a. For QWIPs, only the vertical intensity initiates absorption. The corresponding r_{ie} in Figure 37.22 for the vertical polarization component is 11. Such a large vertical r_{ie} produces a QE of 71% when α becomes finite and equals to 0.2 μm^{-1}, despite the very thin active thickness of 1.2 μm is adopted.

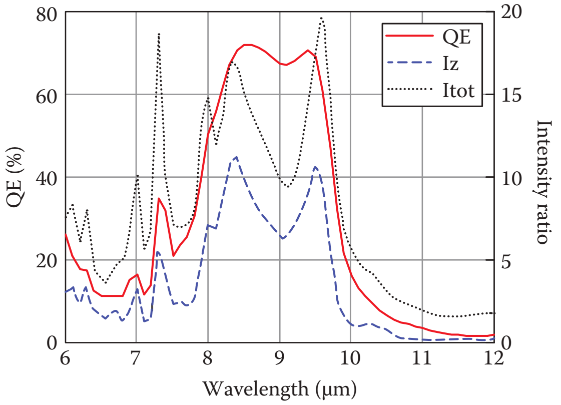

FIGURE 37.22 The calculated r_{ie} for the total intensity (dotted curve) and the vertical intensity (dashed curve) assuming α = 0. The figure also shows the calculated QE (solid curve) if α = 0.2 μm^{-1}. The detector dimension is 22 μm. (DE, diffractive element.)

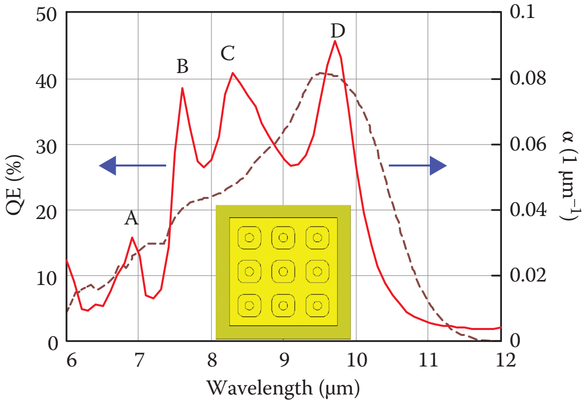

FIGURE 37.23 The measured α spectrum and the modeled quantum efficiency (QE) of an R-QWIP if α = 0.08 μm^{-1}. The pixel size is 20 μm, and the pixel pitch is 25 μm. The insert shows the DE pattern used for optical coupling.

37.5.2 R-QWIP Realization

We have conducted experimental research into R-QWIPs, and found QE as high as 70% in materials with doping larger than 1×10^{18} cm^{-3} (Choi et al., 2013b, 2014, 2015). In this section, we present a more recent R-QWIP to show its advantages. The material consists of 19 QW periods. Each period is made of 50-Å GaAs/60 Å $Al_{0.22}Ga_{0.78}As$/50-Å GaAs/500-Å $Al_{0.22}Ga_{0.78}As$ double-barrier (DW) structure and each well is doped to $N_D = 0.5\times10^{18}$ cm^{-3}. The adoption of the DW structure is to widen the absorption width, and the theoretical peak α is 0.08 μm^{-1} for this N_D. The measured α lineshape based on edge coupling is shown in Figure 37.23. Its bandwidth of 3 μm is about twice that of the single well design. This experimental lineshape and a theoretical peak value of 0.08 μm^{-1} is used for QE modeling. A matching resonator structure for this spectral range is shown in the insert of Figure 37.23. Assuming a λ-independent α of 0.08 μm^{-1} and n = 3.05, the resonator shows four resonant peaks (A, B, C, and D) in Figure 37.23, and the highest peak value is 45%.

The measured *I*–*V* characteristics of the R-QWIP averaged over 1600 pixels are shown in Figure 37.24a, and the QE spectral lineshape measured at −1.1 V averaged over 1000 pixels is shown in Figure 37.24b. Figure 37.24b also shows the calculated spectral lineshape using the material α(λ). It is seen that the relative

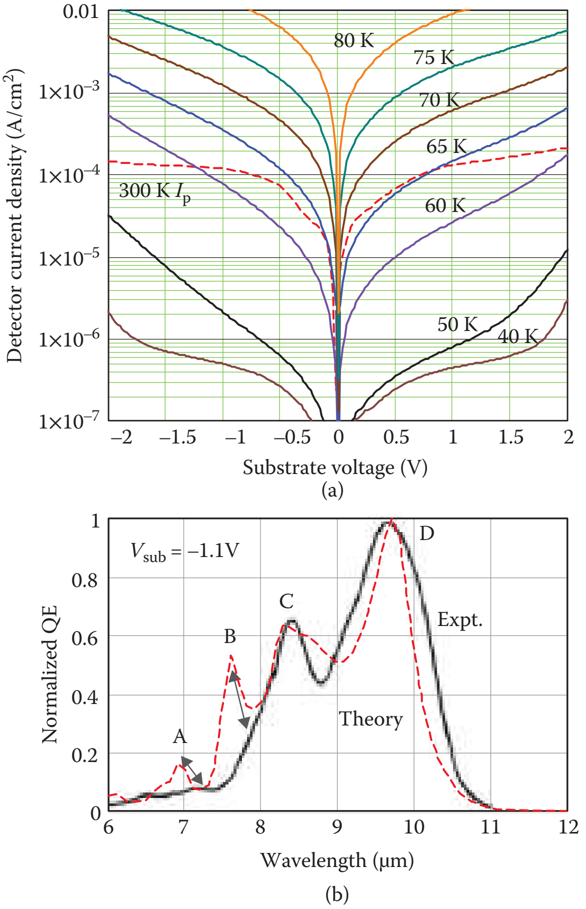

FIGURE 37.24 (a) The average *I*–*V* characteristics of 1600 R-QWIP pixels. (b) The measured average quantum efficiency (QE) lineshape of 1000 pixels in an FPA at −1.1 V and the modeled lineshape.

magnitudes of the experimental C and D peaks are as predicted while those of A and B peaks are much lower. The lower peaks also shift to longer wavelengths. This wavelength shift is expected when a constant n of 3.05 suitable only for 10 μm is used in modeling, while the actual n is known to increase toward shorter wavelengths. In addition to the less accurate n, the E_z distributions shown in Figure 37.25 at λ for A and B peaks indicate that they are higher order resonant modes that require higher precisions in the global structural dimensions. With the presence of processing nonuniformity, these resonances will be reduced.

For the QE magnitude, the main peak at 9.7 μm is measured to be 20% at −2 V and 37% at +2 V. The QE at positive bias is thus consistent with the modeling in this case. The polarity asymmetry is usually observed in R-QWIPs and is related to the highly localized optical intensity created in these detector structures as shown in Figure 37.26. For the two main peaks C and D, E_z is much stronger at the top of the active layer, where the QW layers are more active under positive bias. Therefore, this polarity produces a larger detection QE (Choi et al., 2014). In our simple dark current model described in Section 2.1, we assumed a linear potential drop in the MQW structure. In reality, the potential drop is slightly curved with potential drop near the cathode larger than the anode (Choi, 1997). This nonlinearity makes $\gamma(V)$ in $\eta_{\mathrm{abs}}(\lambda)\gamma(V)$ larger near the top contact region than the substrate under positive bias. While the change of $\gamma(V)$ along z does not affect the average I_{d} with uniformly excited thermal electrons, it does promote larger I_{p} under positive bias when the optical intensity is localized. Therefore, R-QWIPs usually prefer positive bias operation. For future modeling efforts, the inclusion of $n(\lambda)$ and $\gamma(z)$ are clearly needed.

The advantages of the R-QWIPs can be seen by comparing the corrugated-QWIP performance (C-QWIP) in Figure 37.3a and the R-QWIP performance in Figure 37.24a. The C-QWIP uses angled sidewalls to couple normal incident light (Choi et al., 2011, 2012). The cutoff wavelength λ_c of these two materials are similar, which is 11.2 µm for the C-QWIP and 10.6 µm for the R-QWIP. The C-QWIP shows $J_d = 9 \times 10^{-4}$ A/cm^2 at 3 V and 60 K and $J_p = 1.5 \times 10^{-4}$ A/cm^2 at 3 V. For the R-QWIP, $J_d = 2.5 \times 10^{-5}$ A/cm^2 at 1 V and 60 K and $J_p = 1.5 \times 10^{-4}$ A/cm^2 at 1 V. While the difference in the dark currents of the two detectors is a factor of 36, the photocurrents are the same. Accounting for the longer λ_c for the C-QWIP, the R-QWIP improves the I_p/I_d ratio by approximately a factor of 10. Figure 37.27 shows an IR image taken by the present R-QWIP FPA, which shows its excellent sensitivity and uniformity. The FPA operating condition is as follows: temperature = 61 K, applied bias = −1.1 V, $F/\# = 2.5$, signal integration

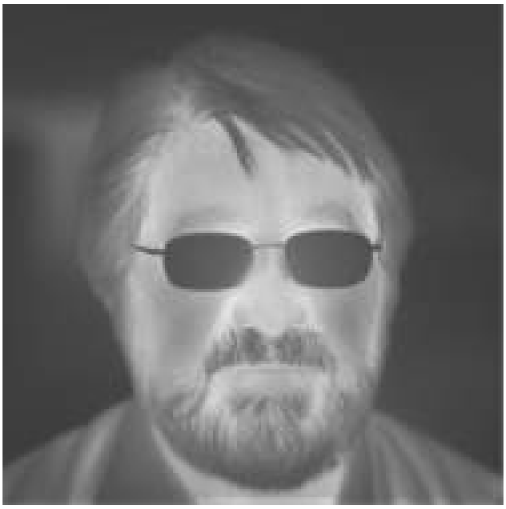

FIGURE 37.27 This image was taken by the R-QWIP FPA with 1024 × 1024 pixels.

time = 3.06 ms, and signal processing = 1-point background subtraction. Under this operating condition, the pixel operability is 99.5% and thermal sensitivity is 45 mK. Even higher sensitivity is expected at a lower temperature or at positive bias.

37.6 Conclusion

In this chapter, we have discussed the theoretical methods in modeling the optoelectronic properties of QWIPs. We found that analytical methods can be used to explain the detector dark current and photoconductive gain. The intrinsic material absorption properties can be calculated from the TMM, and the detector QE can be solved by performing finite-element EM modeling. With these methods, all of the relevant optoelectronic properties of a QWIP can be predicted with very few empirical parameters. This ability greatly facilitates QWIP FPA production, since it allows more consistent and capable products be designed and manufactured.

Due to limited space, some of the advantages of EM modeling have not been discussed. For example, EM modeling can be used to design structures that use thinner materials without antireflection coatings or optical filters to reduce manufacturing cost and improve uniformity; structures that are more immune to fabrication nonuniformity and have less pixel spatial and spectral cross-talk; structures that have special functionality such as extremely narrowband detection, two-color detection, broadband detection, and polarization detection; and structures that are very small in size but are still sensitive so that ultra-high-density FPAs can be produced. For the last benefit, the model predicts that a QE of 56% can be obtained with an absorption coefficient of 0.2 μm^{-1} and pixel size of $5 \times 5\ \mu m^2$. Its realization will enable the production of very high-resolution FPAs with much smaller system size, weight, power, and cost. Besides their usefulness to QWIPs, EM modeling and the photon trap concept are also applicable to other sensors and energy convertors in the IR and other nearby wavelengths. Therefore, one can foresee the increasing vital role played by EM modeling in advancing different optoelectronic technologies in the future.

38.1 Introduction

The modulation of an optical signal is a key requirement of modern optical communications. Even when the transmitter is a laser diode, which can itself be directly modulated, there are advantages of using an unmodulated laser and an external modulator on the output.

Optical modulators can be constructed using many different physical effects. The main ones of interest are as follows:

1. Linear electro-optic, or Pockel's effect—an electrostatic field is used to modulate the refractive index of certain crystals.
2. The plasma effect—the alteration of the free carrier density in a semiconductor can change both the absorption and the refractive index.
3. The Franz–Keldysh (FK) effect and the related quantum-confined Stark effect (QCSE)—where an electrostatic field changes the band structure of a semiconductor, altering both the absorption spectrum and the refractive index.

In choosing a modulator, the following factors should be taken into account:

1. Do you want a phase modulator or an absorption modulator?
2. The modulation bandwidth needed.
3. Its energy efficiency, typically measured in pJ/bit.
4. The optical bandwidth required—some designs are based on resonant structures and can modulate only a narrow range of wavelengths, others can work over very wide optical bandwidths.
5. Size.

There is no such thing as a pure phase modulator or pure absorption modulator. The Kramers–Kronig relationship states that the dispersion spectrum (real part of the refractive index) can be known given the absorption spectrum over all frequencies, and vice versa:

$$\varepsilon'(\omega) = 1 + \frac{2}{\pi} P \int_0^{\infty} \frac{\omega' \varepsilon''(\omega')}{\omega'^2 - \omega^2} \mathrm{d}\omega' \tag{38.1}$$

$$\varepsilon''(\omega) = -\frac{2\omega}{\pi} P \int_0^{\infty} \frac{\varepsilon'(\omega') - 1}{\omega'^2 - \omega^2} \mathrm{d}\omega' \tag{38.2}$$

where the dielectric constant $\varepsilon = \varepsilon' + i \cdot \varepsilon''$, and P is the *Cauchy principal value*. The Kramers–Kronig relationships tell us that the largest change in real index occurs near a change in absorption. Thus the most efficient phase modulators are likely to have absorption at nearby wavelengths.

38.2 QCSE-Based Modulators

38.2.1 Figures of Merit

Design of an electroabsorption modulator (EAM) requires accurate computation of its key characteristics. Among most important figures of merit are (a) on/off ratio defined as the output light power ratio between on and off states of the EAM; (b) the change in absorption coefficient per unit applied voltage; and (c) maximum data transmission speed. Calculating (a) and (b) is based on accurate modeling of absorption spectrum as a function of applied voltage, which will be the main focus of this chapter. Computing (c) involves modeling carrier dynamics. A detailed account of the latter can be found in [1–3].

38.2.2 Structure

Let us consider a typical traveling-wave EAM shown in Figure 38.1. This type of structure is used in this chapter as an example. Although other configurations have been reported as well (e.g., VCSEL-type EAM [4]), the traveling-wave type is the most common and the general principles of its operation can be extended to others with some modifications.

In a traveling-wave configuration, the light propagation dimension (z in Figure 38.1) is much greater than light- and carrier-confining dimensions (x and y in Figure 38.1) and, therefore, z can be separated from the x and y for computational efficiency. This means that we can split the device along axis z into a finite

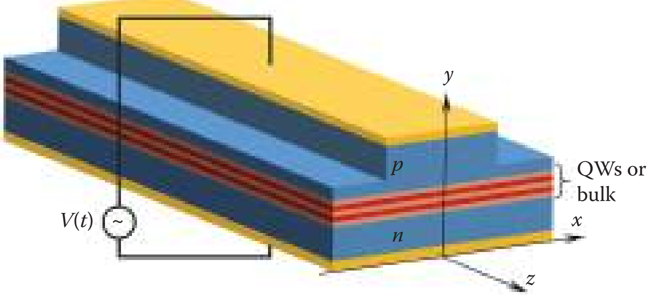

FIGURE 38.1 Traveling-wave EAM structure. The light signal propagates in the z-direction. Light confinement in the x–y plane can be realized via various configurations, the rigde waveguide shown in the figure being just one example. Epitaxial layers are grown in the y-direction. Top and bottom layers are metallic contacts. QWs and barriers comprise the active region. Next to the metallic contact layers are the substrate (n-doped) and cladding (p-doped). (QW=quantum well.)

number of short segments and assume optical properties within each segment to be z-independent, thus reducing the problem of modeling the optical properties to two transversal dimensions, x and y. Furthermore, in many cases, when the variation of the optical field and carrier density in one transversal direction (e.g., y in Figure 38.1) is much greater than in the other, the problem becomes one-dimensional. Then the calculated optical properties, namely, *material absorption* and *refractive index*, are used as input to an optical mode solver to compute the *effective index* and *modal absorption* of a particular waveguide mode that carries the optical signal. Finally, the result is passed as input to a one-dimensional z-propagation algorithm to obtain the device's characteristics. The first stage of this sequence, modeling material absorption and refractive index, is the focus of this chapter.

The optical absorption in EAMs is caused by several processes, among which are carrier transitions between conduction and valence band, free-carrier absorption (FCA), intraband transitions, photon–phonon interaction, etc. By far, the strongest contribution within the relevant spectral bandwidth is made by the first of these. It can be controlled by electrical bias applied across the epitaxial structure via one of the two main physical mechanisms: the FK effect in bulk layer structures or the QCSE in quantum wells (QWs). It is the latter one that is used in the majority of EAMs due to its higher efficiency. However, the FK effect is briefly examined here for the benefit of general understanding of these two phenomena.

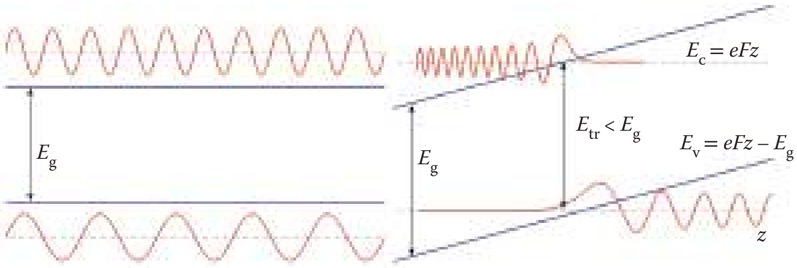
38.2.3 Franz–Keldysh Effect

The Franz–Keldysh (FK) effect is the change in photon absorption spectrum induced by reverse bias applied to a bulk semiconductor structure (Figure 38.1). In an unbiased bulk layer, the electron and hole states are represented by space-harmonic functions. The probability of a photon-absorbing transition between two states is proportional to the overlap integral between their respective wavefunctions. When electric field F is applied across spatial direction y, the electron and hole wavefunctions change their shape and become Airy functions as shown in Figure 38.2b.

As the overlap integral between them changes, the probability of the photon absorption changes accordingly. Furthermore, the minimum absorption frequency falls below the bandgap, as can be seen from Figure 38.2b. This enables the control of the transmitted power of the light traveling through the EAM with applied voltage at a given wavelength (Figure 38.3). However, absorption change per applied voltage is relatively low and QW structures are preferred due to the higher efficiency of the QCSE.

38.2.4 Quantum-Confined Stark Effect

The QCSE is a counterpart of the FK effect in QW structures. It has, however, an additional feature: the presence of thin peaks in the absorption spectrum caused by the excitonic transitions. Indeed, unlike the bulk structures, QWs facilitate strong electron and hole confinement (see Figure 38.4), which causes



(a) (b)

FIGURE 38.2 Electron and hole wavefunction in (a) an unbiased bulk semiconductor with bandgap E_g and when (b) a constant electric field F is applied across spatial direction y.

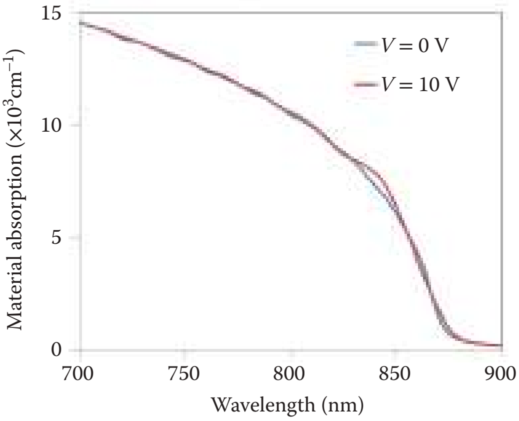


FIGURE 38.3 Change in absorption spectrum in 70-nm bulk AlGaAs under reverse bias due to the FK effect.

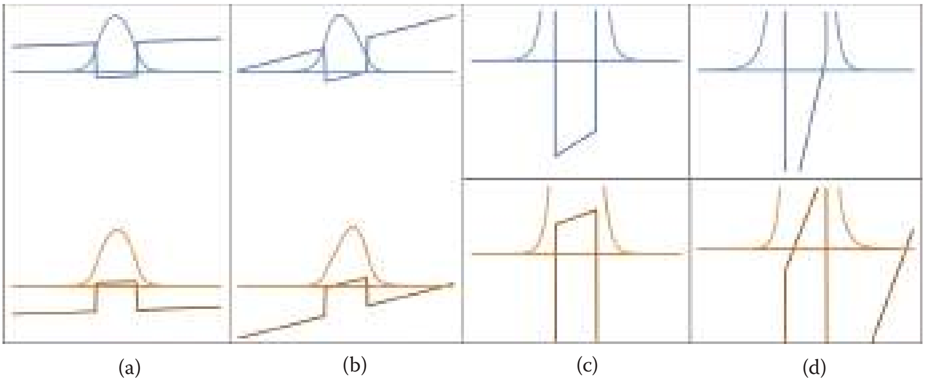

FIGURE 38.4 QW potential, electron and hole wavefunctions (a) without and (b) with a reverse bias. Plots (c) and (d) are (a) and (b), respectively, zoomed in to demonstrate the redshift in the energy levels.

the two carrier types to form bound states, *excitons*, similar to those between a proton and an electron in a hydrogen atom. These states introduce new discrete energy levels in addition to those of the QWs: but whereas the contribution to the absorption spectrum from the QW transitions has a staircase-like shape, the exciton contribution appears as peaks in the absorption spectrum.

Like in bulk layers, applying a reverse bias to the QW potential creates a double effect (see Figure 38.4). First, the electron and hole wavefunctions start "escaping" through the lower potential barrier, which decreases their overlap and, consequently, the probability of photon absorption. Second, their energy levels move closer to one another, which results in the redshift of the respective absorption peaks.

It can be seen from Figure 38.5 that if the absorption is measured at wavelength λ_0 near the exciton peak, the net effect of the two phenomena is the *increase* in absorption. This enables the control of the amount of light passing through the EAM by varying electric bias applied to the device. The material absorption change is much higher than in the case of the bulk structure. However, the material absorption is factored by the optical confinement factor, which is much smaller in QWs. To overcome this problem, multiple quantum wells (MQWs) are normally used to increase the efficiency of the device.

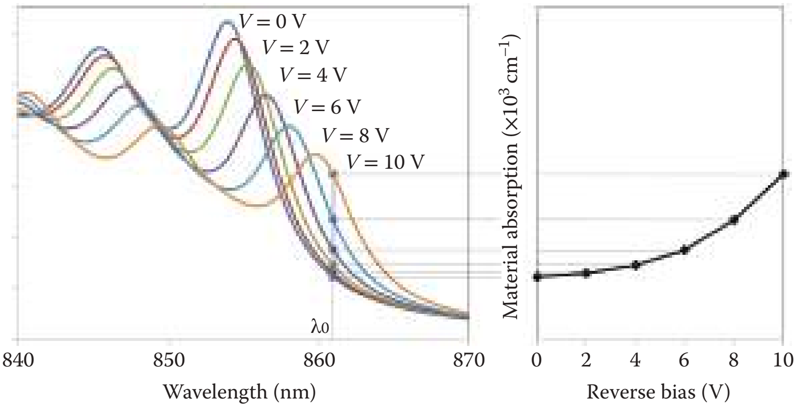

FIGURE 38.5 Change in material absorption spectrum in a 10-nm single QW AlGaAs EAM under reverse bias due to the QCSE effect. The peaks represent exciton's positions.

38.2.5 Modeling Absorption Spectrum

Modeling of the absorption spectrum as a function of voltage bias consists of several stages. Two most important effects contributing to the absorption is the carrier transitions between (a) energy levels created by QW confinement and (b) exciton binding energy levels. Photon absorption rate is proportional to the probability of the transition between an occupied state n in the valence band (hole) and an unoccupied state m in the conduction band (electron) multiplied by the Fermi population level $\alpha_{mn} \propto P_{mn}(f_m - f_n)$. The total absorption is given by the double sum over all relevant transitions mn, while each probability P_{mn} is determined from the overlap between the respective electron and hole wavefunctions. Therefore, the central part of the modeling is solving the Schrödinger equation in the QW potential and with an excitonic term added to its Hamiltonian. The QW potential, in its turn, is created by the juxtaposition of epitaxial layers with different bandgaps and applied electric field. It can be calculated using the Poisson-drift-diffusion model. In the case of EAMs, the coupling between the Schrödinger and Poisson equations can be neglected, which significantly reduces computational load.

38.2.6 Poisson-Drift-Diffusion Model

The Poisson-drift-diffusion model is based on three first-order differential equations: the carrier continuity equations for electrons and holes and the Gauss's law (see Chapter 3.1 in [5]),

$$\begin{aligned}\frac{\partial n}{\partial t} &= G_n - R_n - \nabla \cdot (\mu_n n \nabla \phi - D_n \nabla n)\\ \frac{\partial p}{\partial t} &= G_p - R_p - \nabla \cdot (\mu_p p \nabla \phi - D_p \nabla p)\end{aligned} \tag{38.3}$$

$$0 = \nabla \cdot \varepsilon \nabla \phi + q_e(p - n + N_D + N_A) \tag{38.4}$$

where $n = n(\boldsymbol{\rho}_{xy})$, $p = p(\boldsymbol{\rho}_{xy})$ are the electron and hole densities; $\boldsymbol{\rho}_{xy} = \{x, y\}$ is the spatial coordinate; $G_{n,p}(\boldsymbol{\rho}_{xy})$ and $R_{n,p}(\boldsymbol{\rho}_{xy})$ are generation and recombination rates, respectively; $\mu_{n,p}(\boldsymbol{\rho}_{xy})$ is electron and hole mobilities; $D_{n,p}(\boldsymbol{\rho}_{xy})$ is the electron and hole diffusion coefficients; $\varphi(\boldsymbol{\rho}_{xy})$ is the static field potential; $\varepsilon(\boldsymbol{\rho}_{xy})$ is the electric permittivity; $N_{D,A}(\boldsymbol{\rho}_{xy})$ is the donor and acceptor doping levels; and q_e is the electron charge.

Since in most EAMs the carrier density is very low, the generation and recombination terms can be discarded. With the reverse bias, the currents are also assumed negligible and, therefore, for the steady-state solution, the time derivatives are set to zero:

$$\begin{aligned} \nabla\cdot(\mu_n n\nabla\phi - D_n\nabla n) &= 0\\ \nabla\cdot(\mu_p p\nabla\phi - D_p\nabla p) &= 0\\ \nabla\cdot\varepsilon\nabla\phi + q_\mathrm{e}(p - n + N_\mathrm{D} + N_\mathrm{A}) &= 0 \end{aligned} \tag{38.5}$$

Equation 38.5 is solved with respect to $\{n, p, \varphi\}$, whereas $\mu_{n,p}$, $D_{n,p}$, ε, and $N_{\mathrm{D,A}}$ are usually assumed to be independent of $\{n, p, \varphi\}$ and are precomputed from the epitaxial layer composition. The potential φ is then used to find the spatial profile of the band edges:

$$E_{\mathrm{c,v}}(\boldsymbol{\rho}_{xy}) = E_{\mathrm{c0,v0}}(\boldsymbol{\rho}_{xy}) - \phi(\boldsymbol{\rho}_{xy}) \tag{38.6}$$

In addition to static field potential, the Poisson-drift-diffusion model calculates the distribution of carriers and, consequently, the distribution of charge in the PIN-junction as a function of applied bias. This is essential for calculating the device's characteristics in an electric circuit, such as capacitance, resistance, and, eventually, the modulation response.

38.2.7 Schrödinger Equation for QW States and Excitons

The next step after finding the band edge potentials $E_{\mathrm{c,v}}(\boldsymbol{\rho}_{xy})$ is to solve the Schrödinger equation in order to find energy levels and spatial distributions of electron and hole wavefunctions. There exist several methods to do so, with different tradeoffs between accuracy and computational efficiency. The general form of the Schrödinger equation is

$$\hat{H}\Psi = E\Psi \tag{38.7}$$

The Hamiltonian operator $\hat{H}$ in the presence of excitonic effect is split into electron, hole, and exciton parts [6]:

$$\begin{aligned} \hat{H} &= \hat{H}^\mathrm{e} + \hat{H}^\mathrm{h} + \hat{H}^\mathrm{exc}\\ \hat{H}^\mathrm{e} &= \hat{H}^\mathrm{e}_\mathrm{kin} + E_\mathrm{c}(\boldsymbol{r}_\mathrm{e})\\ \hat{H}^\mathrm{h} &= \hat{H}^\mathrm{h}_\mathrm{LK} + E_\mathrm{v}(\boldsymbol{r}_\mathrm{h}) \end{aligned} \tag{38.8}$$

where $\hat{H}^\mathrm{e}_\mathrm{kin} \propto \nabla^2_\mathrm{e}$ is the kinetic part of the electron Hamiltonian, $E_{\mathrm{c,v}}(\mathbf{r}_{\mathrm{e,h}})$ is the QW potentials with applied bias for conduction and valence bands, respectively, as calculated by solving Equations 38.5 and 38.6. Note that the spatial coordinates for electrons and holes are different. $\hat{H}^\mathrm{h}_\mathrm{LK}$ is the Luttinger–Kohn Hamiltonian for holes. The latter can be a 4×4 matrix operator, in case if only heavy and light holes are taken into account [6]. When highly strained structures are considered, the influence of the spin-orbit split-off band becomes significant and it needs to be included in $\hat{H}^\mathrm{h}_\mathrm{LK}$, increasing its size to a 6×6 matrix operator [29,30]. The exciton part, $\hat{H}^\mathrm{exc}$, is due to the Coulomb interaction between electron and holes. The additional term in the Hamiltonian of the system is, therefore,

$$\hat{H}^\mathrm{exc} = \frac{q_\mathrm{e}}{4\pi\varepsilon_0\varepsilon}\frac{1}{|r_\mathrm{e} - r_\mathrm{h}|} \tag{38.9}$$

As the first step, the energies and the wavefunctions of the conduction and valence bands without the exciton contribution are obtained by solving the Schrödinger equation with respective Hamiltonians:

$$\begin{aligned}\hat{H}^{\mathrm{e}}\psi_m^{\mathrm{e}}(\mathbf{k},\mathbf{r}) &= E_m^{\mathrm{e}}\psi_m^{\mathrm{e}}(\mathbf{k},\mathbf{r})\\ \hat{H}_{\mathrm{LK}}^{\mathrm{h}}\psi_n^{\mathrm{h}}(\mathbf{k},\mathbf{r}) &= E_n^{\mathrm{h}}\psi_n^{\mathrm{h}}(\mathbf{k},\mathbf{r})\end{aligned} \tag{38.10}$$

It is assumed that the scale of the spatial variation of parameters in the x- and z-directions is insignificant in comparison to that in y-direction. The solution of these equations is, therefore, obtained by separating their spatial dependence: the wavefunction is assumed to be harmonic in the x- and z-directions and (Equation 38.10) is reduced to a one-dimensional eigenvalue problem with a y-dependent Hamiltonian only (note that in some references quoted here the perpendicular axis is denoted z, not y).

The one-dimensional Schrödinger equation can be solved using a finite-difference method or a so-called "shooting" method. In the case of the effective mass approximation (parabolic dispersion relation $E(\mathbf{k}_{xz})$), it only needs to be solved for $\mathbf{k}_{xz} = 0$, where $\mathbf{k}_{xz}$ is an in-plane wave vector (see, e.g., [7]).

If nonparabolicity of the dispersion curve needs to be taken into account, Equation 38.10 must be solved for a range of $\mathbf{k}_{xz}$ in the vicinity of zero. This can present a considerable computational challenge. The axial approximation removes the dependency of $\hat{H}_{\mathrm{LK}}^{\mathrm{h}}$ on azimuthal angle θ and the two-dimensional vector $\mathbf{k}_{xz}$is replaced with its magnitude k, which significantly reduces computational time (see, e.g., [6]).

After the energies and wavefunctions in Equation 38.10 are found, the second step is to compute the exciton transition energy levels and wavefunctions with the full Hamiltonian:

$$\hat{H}\,\Psi^X(\mathbf{r}_{\mathrm{e}},\mathbf{r}_{\mathrm{h}}) = E^X\Psi^X(\mathbf{r}_{\mathrm{e}},\mathbf{r}_{\mathrm{h}}) \tag{38.11}$$

Here X denotes different exciton states, such as 1s, 2s, 2p, etc., called so by analogy with the atomic states. Two main methods of solving this problem are the momentum-space method [6] and the variation method [7].

In the momentum-space method, the exciton function is expanded in terms of conduction and valence wavefunctions $\psi_n^{\mathrm{e}}(\mathbf{k}_{xz}, y_{\mathrm{e}})$ and $\psi_m^{\mathrm{h}}(\mathbf{k}_{xz}, y_{\mathrm{h}})$ (found by solving Equation 38.10) in the $\mathbf{k}_{xz}$ space. As a result, Equation 38.11 is reduced to an eigenvalue problem with the integral operator on the right-hand side (see Equations 38.18 and 38.19 in [6]). Similarly to Equation 38.10, the axial approximation can be applied to full Hamiltonian $\hat{H}$: vector $\mathbf{k}_{xz}$ is replaced with its absolute value k, and the dependence of the wavefunctions on the azimuthal angle is confined to the phase term only: $\varphi(\mathbf{k}_{xz}) \to \varphi(k)e^{j\theta l}$. As mentioned earlier, the exciton states with $l = 0, \pm1, \pm2$, and ±3, are s, p, d, and f.

The exact mathematical details can be found in [6], but it is important to mention here that the final equation will contain a quadruple integral: over the spatial domain of the electron wavefunctions y_{e}, over that of the hole wavefunctions y_{h} spatial domain, and over the momentum angle of the in-plane vector $\mathbf{k}$; and over its magnitude k. The method was demonstrated to be in excellent agreement with the experimental results [6]. However, computing the quadruple integral for large structures (on the order of tens of nanometers in y-direction) can become prohibitively slow.

The variational method [7] is used to increase computational efficiency, albeit at the cost of accuracy. The exciton function in Equation 38.11 is expanded in terms of conduction and valence wavefunctions in real space ρ, not $\mathbf{k}$. Only the 1s exciton state is taken into account (so that the θ dependence is dropped, $\boldsymbol{\rho} \to \rho$):

$$\Psi^{1s}(\rho, y_{\mathrm{e}}, y_{\mathrm{h}}) = \phi_{mn}^{1s}(\rho)\psi_m^{\mathrm{e}}(y_{\mathrm{e}})\psi_n^{\mathrm{h}}(y_{\mathrm{h}}) \tag{38.12}$$

where $\phi_{mn}^{1s}(\rho)$ is a 1s trial function with variational parameter λ:

$$\phi_{mn}^{1s}(\rho) = \sqrt{\frac{2}{\pi}}\frac{e^{-\rho/\lambda}}{\lambda} \tag{38.13}$$

38.2.8 Permittivity Spectrum

Equations 38.7 through 38.13 serve to calculate the spectral positions of the exciton and QW transitions. The next step is to calculate the strength and the shape of the absorption $\alpha(\omega)$ as a function of light frequency ω due to these transitions and the corresponding change in the refractive index $n_{\text{re}}(\omega)$, both making part of the complex permittivity $\varepsilon(\omega) = [n_{\text{re}}(\omega) + i\alpha(\omega)c_0/(2\omega)]^2$, where ω is the angular frequency of light and c_0 is the speed of light in vacuum. The expression for total complex permittivity can be written as

$$\varepsilon(\omega) = \varepsilon^{\text{opt}} + \sum_{m(\text{e})} \sum_{n(\text{h})} (\varepsilon_{mn}^{\text{QW}}(\omega) + \varepsilon_{mn}^{\text{exc}}(\omega)) \tag{38.14}$$

where ε_{opt} is the permittivity for low optical frequencies, $\varepsilon_{mn}^{\text{QW}}(\omega)$ and $\varepsilon_{mn}^{\text{exc}}(\omega)$ is the permittivity change due to the QW and exciton transition between hole state n and electron state m. Whereas the QW contribution is a staircase-like function with steps located at energies $(E_m - E_n)$, the exciton transition is a delta function found at energies $(E_m - E_n - E_X)$. The exact formulae for the momentum-space and variational methods can be found in [6,7], respectively.

Two things must be pointed out. First, as mentioned earlier, the contribution both to the QW "steps" and exciton peaks is proportional to the overlap integral between the respective hole and electron functions:

$$\varepsilon_{mn}^{\text{QW,exc}}(\omega) \sim \int \psi_m^{\text{e}}(y)\psi_n^{h*}(y)dy \tag{38.15}$$

Second, due to the finite lifetime of the exciton states, these peaks have a spectral width $\simeq 1/\tau_{\text{exc}}$. Similarly, the steps of the staircase-like function of the QW contribution are smoothed out by a QW linewidth function, whose width is inversely proportional to the lifetime of the QW states. Mathematically, it is expressed as a convolution integral between $\varepsilon_{mn}^{\text{QW,exc}}(\omega)$ and respective linewidth functions $L_{mn}^{\text{QW,exc}}(\omega)$. The latter are complex-valued functions satisfying Kramers–Kronig relations (Equations 38.1 and 38.2) and they contribute to both the real and imaginary parts of the complex permittivity. Strictly speaking, each electron–hole pair should have its own $L_{mn}^{\text{QW,exc}}(\omega)$, but often in practice the same function is used for all pairs mn. There have been a few publications dedicated to calculating the shape of $L^{\text{QW,exc}}(\omega)$ (see, e.g., [9]). Still in many cases, a simple Lorenzian shape with an experimentally measured spectral width is used in calculations with satisfying accuracy [6].

38.2.9 Numerical Results

Below, experimental and modeling results are shown for several structures. Figure 38.6 shows the comparison between experimental results obtained for an SiGe modulator [10] and those simulated using the variational method. The variational method demonstrates excellent agreement in positions and shapes of the primary excitonic peaks and their dependence on the applied electric bias. It is not as accurate, however, in modeling higher energy spectra.

Furthermore, experimental results for an AlGaAs EAM, reported in [6], are compared with curves computed by the variational method and the momentum-space method (Figure 38.7).

It can be seen that the latter captures the general shape of the curve much more accurately, especially at higher energies. It can be argued, however, that the working frequency of the EAM is below the bandgap (to the left of the excitonic peak at zero bias) and it is, therefore, the most important spectral area to model. Moreover, the behavior in this area is largely dependent on the correct modeling of the exciton shape, not covered by either of the methods (see [9]). Therefore, in many cases, the variational method is preferred as a computationally fast alternative of the momentum-space method, especially for large MQW structures.

Absorption spectra for various values of the bias voltage: (a) experimental data from; (b) simulated curves using variational method for (top) TE polarization and (bottom) TM polarization; and (c) simulated curves using momentum-space method.

38.3 Electro-Optic Effect Modulators

The linear electro-optic effect, otherwise known as the Pockel's effect is present in crystals that do not have an inversion symmetry. This means they need an anisotropic dielectric tensor. Popular materials exploiting the Pockel's effect include $LiNbO_3$, $LiTaO_3$,and β-barium borate (BBO). The Pockel's effect is effectively instantaneous, once the electrostatic field has been established, making it suitable for exceedingly high-speed modulators.

$LiNbO_3$ has been a very popular material for electrorefractive modulators for many years because of its relatively large electro-optic coefficient [11,12], i.e., variation of refractive index with an applied electrostatic field. The rest of this section focuses on $LiNbO_3$ not because it is the only material available, but because of its dominant industrial position in photonics.

$LiNbO_3$ is strongly anisotropic implying a nontrivial dielectric tensor ε_{ij}. Since the tensor is symmetric, the double indexing conventionally simplified as

$$\begin{pmatrix} D_x \\ D_y \\ D_z \end{pmatrix} = \begin{pmatrix} \varepsilon_1 & \varepsilon_6 & \varepsilon_5 \\ \varepsilon_6 & \varepsilon_2 & \varepsilon_4 \\ \varepsilon_5 & \varepsilon_4 & \varepsilon_3 \end{pmatrix} \begin{pmatrix} E_x \\ E_y \\ E_z \end{pmatrix} \tag{38.16}$$

In addition, the variation of each $\varepsilon_{\mathrm{ij}}$ with applied electrostatic field depends on the direction of the electrostatic field E, leading to a second-rank tensor:

$$\Delta\left(\frac{1}{\varepsilon_i}\right) = \sigma_{ik}E_k \tag{38.17}$$

This implies that different optical polarizations will experience different modulations. In $LiNbO_3$, only a few of the electro-optic tensor coefficients are significant:

$$\sigma_{13} = 8.6\ \mathrm{pm/V}, \sigma_{22} = 3.4\ \mathrm{pm/V}, \sigma_{33} = 30.8\ \mathrm{pm/V}, \sigma_{51} = 28\ \mathrm{pm/V} \tag{38.18}$$

Unlike for example, silicon modulators, there is no macroscopic movement of charge except that associated with the capacitance of the dielectric: $C = \epsilon_r\epsilon_0 A/d$; d is thickness, A is area. This leads to a very high-speed modulator capable of working to 30 GHz or more [13]. In fact, the change in refractive index is near instantaneous once the electric field has been established and the speed of an $LiNbO_3$ modulator is limited almost entirely by it capacitance and the speed of the electrical circuit driving it.

As the electro-optic tensor coefficients given earlier imply, the effect is anisotropic in both the direction of the applied field and in the modulation of the optical dielectric tensor. The crystal must be carefully oriented to obtain the desired effect. The two favored orientations are denoted x-cut and z-cut. An x-cut crystal will create a strong modulation of a TE-like polarized optical mode in response to an electrostatic field in the same transverse axis as the optical one, exploiting the σ_{33} coefficient. An x-cut crystal requires a vertical electrostatic field to modulate the same TE-like polarized optical mode and exploits the σ_{51} coefficient.

38.3.1 The Mach–Zehnder Modulator

The change in refractive index can be converted to a change in signal amplitude using a Mach–Zehnder interferometer design (Figure 38.8). With sufficient voltage, a 180°phase shift between the two optical paths is created by the time the waveguides combine, causing full cancellation of the signal.

A modulator can be made using a field between an electrode placed on top of the $LiNb0_3$ chip and a ground plane underneath. However, since the chip is rather thick, this leads to a low field strength, so typically both electrodes are placed on top of the chip either side of the waveguide, as shown in Figure 38.9.

The design in Figure 38.9 has one big flaw. The electrodes are very close to the optical mode; this causes substantial optical losses especially in the TM-like polarization. To cure this, a cap layer can be deposited on the $LiNbO_3$ before the electrodes are deposited. The buffer has another advantage in that it alters the velocity of the electrical signal along the modulator, allowing it to better match the velocity of the optical signal. This substantially improves the modulation bandwidth.

The disadvantage of the buffer is a reduction in electric field strength in the vicinity of the optical mode, requiring a longer modulator to achieve the same phase change. In Figure 38.10, you can see the voltage contours of a design with a 100-nm SiO_2 buffer. Notice that a lot of potential is dropped across the buffer layer. This typically leads to a ~30% drop in modulator efficiency.

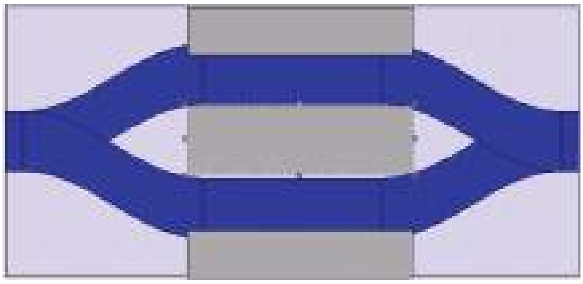

FIGURE 38.8 An $LiNbO_3$ modulator based on a Mach–Zehnder interferometer. A 3-dB splitter divides the input signal between two arms. One arm is given a positive electric field and the other arm a negative field, creating an increase in mode effective index in one branch and a similar decrease in effective index in the other.

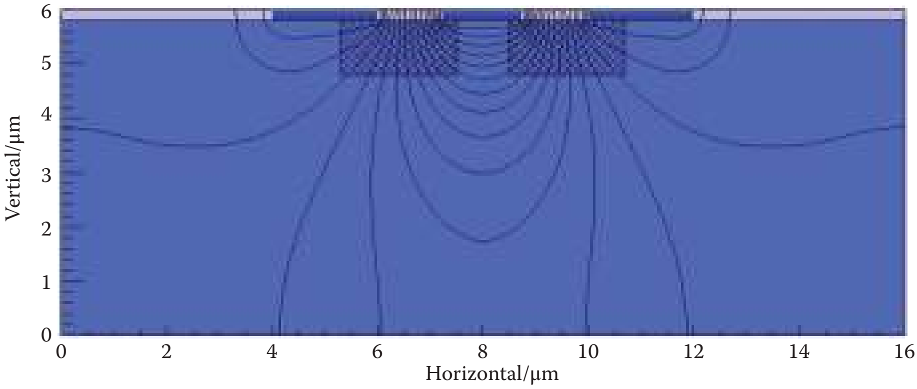

FIGURE 38.9 Cross section of a typical x-cut $LiNbO_3$ Mach–Zehnder modulator showing the Ti-diffused waveguides (hashed), three electrodes on top of the structure and electric potential contour lines. Typically, the outer electrodes are grounded and the central one carries the modulating signal. The opposite electrostatic field direction across each waveguide creates a natural push-pull effect for the Mach–Zehnder modulator. Note how the strongest field is generated in the middle of the waveguides.

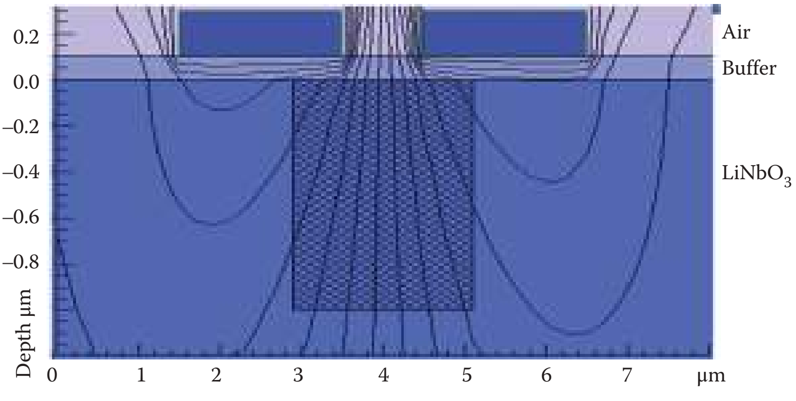

FIGURE 38.10 An x-cut $LiNbO_3$ modulator cross section with a cap layer creating an offstand between the electrodes and the optical mode. But note the strong field drop across the cap layer. This will reduce the electric field in the vicinity of the optical mode.

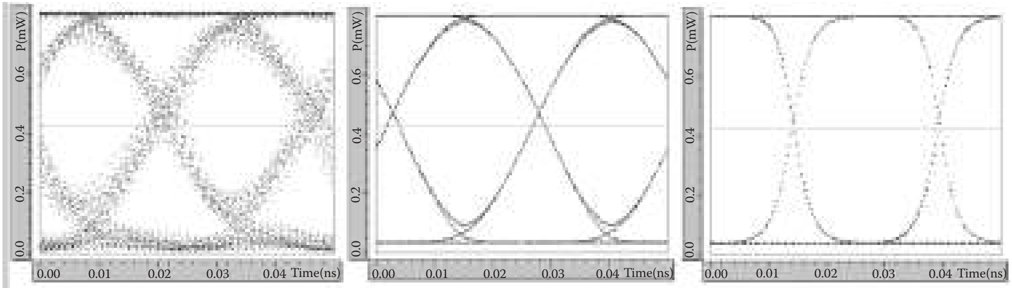

FIGURE 38.11 Eye diagrams of a traveling-wave $LiNbO_3$ MZI modulator at 40 Gb/s, computed with an optical circuit simulator PicWave [14] that includes traveling-wave time domain models for both the optical field and the electrodes: (left) with an unmatched electrode contacted a few millimeters from the end of the 20-mm-long modulator; (middle) contacted at the end; and (right) with a velocity-matched electrode.

38.3.2 Traveling-Wave Design

Because the change in effective index with voltage is typically very small, ~0.0001 per volt, the modulator has to be very long. This means that both the optical signal and the electrical signal will take a significant time to travel along the device. In order to maximize the modulation bandwidth, it is advantageous to match the velocity of the optical and electrical signals by appropriate design of the electrodes. Figure 38.11 shows some simulations of a traveling-wave $LiNbO_3$ Mach–Zehnder modulator under 40 Gb/s NRZ data stream. The figures show “eye diagrams” of the modulation response. To create an eye diagram the circuit is driven by a random bit sequence, and response of each clock period is superimposed. A clear open “eye” indicates a good signal.

38.4 Plasma-Effect Modulators

The plasma effect is the name given to the interaction of free electrons with an optical field. A plasma naturally occurs in a metal, which is why all metals are opaque. In order to make a modulator, one needs a way to control the carrier density, which is not realistic in a metal. In a semiconductor, the free-carrier population can be readily controlled by either injecting carriers into a diode (forward bias) or by lightly doping a region of the semiconductor and using a gate electrode or a reverse-biased junction to create an electrostatic field to deplete the carriers from the lightly doped region.

This section focuses on silicon-based plasma-effect modulators. Silicon is becoming a popular platform for manufacturing photonic components, largely because of the benefits of access to the huge electronic silicon manufacturing industry, its mature foundries and tools. Although silicon is not capable of generating light efficiently, i.e., making a laser, it is capable of absorbing light or modulating its phase by controlling the plasma effect in the optical path. Silicon optical modulators are now capable of reaching tens of gigahertz modulation speed, nearly rivalling the best $LiNbO_3$ modulators and in a much smaller volume, with much lower power requirements.

38.5 Si Electroabsorption versus Electrorefractive Effect

Silicon can act as an optical modulator either by a variation of the optical absorption in the silicon [15]—an “electroabsorptive modulator” or more popularly by modulation of the refractive index [16–19]—a so-called “electrorefractive modulator”. In fact this distinction is somewhat arbitrary, since all changes in the real part of the refractive index will cause a change in the imaginary part, and vice versa. As discussed in Introduction, the real and imaginary changes do not generally happen at the same wavelength and the relationship is described by the so Kramers–Kronig relationship. At a wavelength of 1.55 μm and for low doping densities, the real and imaginary changes are given approximately by [17]

$$\Delta n = -8.8x10^{-22}\Delta N - 8.6x10^{-18}\,(\Delta P)^{0.8}$$

$$\Delta\alpha = +8.5 \times 10^{-18}\Delta N + 6 \times 10^{-22}\Delta P$$

A big disadvantage of an electrorefractive modulator is that usually we want to modulate the amplitude of an optical signal and to create an amplitude modulation out of such a modulator generally requires interference effects in for example, a Mach–Zehnder interferometer [18–20] or a ring resonator [16,17, 21,22]. Both of these have a strong wavelength-dependent response, especially the ring resonator. Despite this, silicon electrorefractive modulators have arguably had the greater impact due to their lower power and higher modulation bandwidths.

Some of the earliest silicon modulator designs are based on carrier injection in a PIN diode [20–22]. Here a forward current is injected into the diode and the free charge carriers in the intrinsic region cause a change in refractive index. Figure 38.12 shows the cross section of a typical carrier-injection PIN diode modulator. The effect is only weakly dependent on wavelength, though once included in a Mach–Zehnder or resonant cavity structure, this advantage is lost. The effect is however only weakly dependent on temperature unlike QCSE or other bandgap-dependent effects.

An alternative Si modulator structure reverse biases a pn (or PIN) junction [18,19,23,24]. The reverse bias causes carrier depletion in the junction, and an associated alteration of the local refractive index. Figure 38.13 shows a possible geometry, one with a vertical junction [8]. In general, it is preferable to move the p-n junction to one side so most modulation is done by p-type carriers. This is because the p-carriers create less absorption at wavelengths of interest for a given modulation depth, since the absorption peak is moved further out.

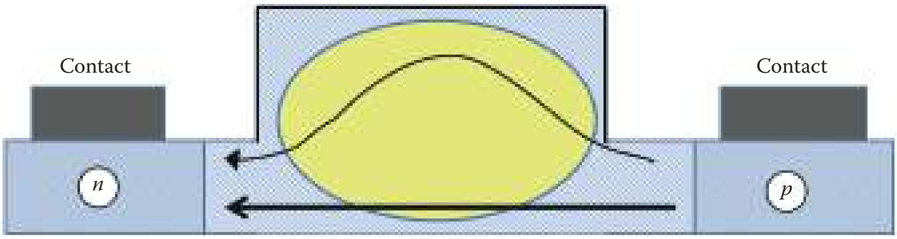

FIGURE 38.12 A PIN diode type silicon optical modulator. The silicon is etched to form a rib waveguide in the intrinsic region. Forward current interacts with the optical mode in the rib, changing its velocity or effective index.

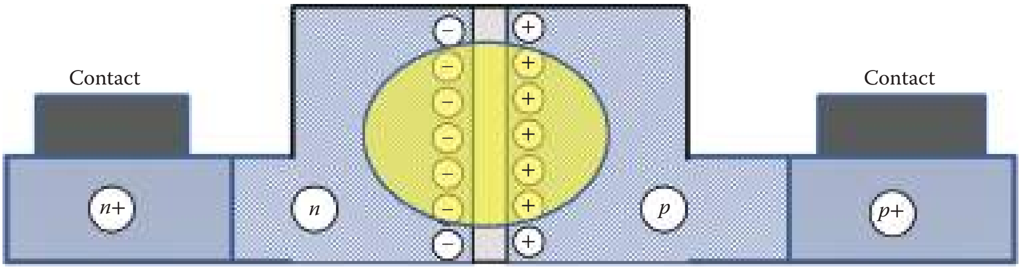

FIGURE 38.13 A reverse-bias type Si optical modulator. In these designs, the reverse bias caused electrostatic charge to build up at the p-n junction. These charges change the local refractive index.

Geometries similar to the former with asymmetric p-n junction have achieved a Vπ of 10 V in a 1-mm waveguide and bandwidths in excess of 50 Gb/s for a 1-mm long asymmetric Mach–Zehnder interferometer [19]. An experimentally measured eye diagram from this modulator is shown in Figure 38.14.

Figure 38.15 shows a recent design with a horizontal junction corresponding to a capacitor device [23]. The device is forward biased to cause carrier accumulation across the capacitor. This device achieved a modulation capability of 10 Gb/s at a length of 625 μm. Because the p and n carriers are close to each other, this design does not avoid the higher absorption of the n-type carriers.

Although most Si optical modulators are primarily electrorefractive, some electroabsorptive modulators have been demonstrated. In this case the free carriers are increased to a sufficient density that substantial FCA occurs. FCA is caused by carriers close to the band edge absorbing a photon and being excited to a state further up the conduction band (electrons) or down into the valence band (holes). The excited carriers then rapidly lose their energy by nonradiative transitions. An interesting design was recently proposed based on a Schottky diode [25]. The structure is predicted to reach a 3-dB bandwidth at 7 GHz for a 500-μm-long traveling-wave design. This is equivalent to a data rate of over 15 Gb/s using NRZ coding. Other groups have demonstrated EAMs using SiGe QWs—the QCSE effect (see Section 38.2) or by depositing graphene on the silicon [15,26,27].

	Current	Minimum	Maximum	Total meas
Ext.ratio(14)	2.20 dB	2.20 dB	2.20 dB	43
Bit.rate(14)	50.0 Gb/s	49.7 Gb/s	50.0 Gb/s	43

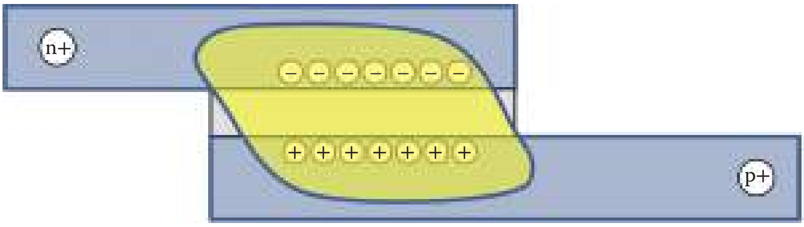

FIGURE 38.15 A capacitor-like structure also works by charge build up at the interface.

38.6 Resonant Modulators

In previous paragraphs, we outlined the use of traveling-wave designs such as the Mach–Zehnder interferometer to implement a modulator. Because the change in refractive index tends to be small for most modulator effects, this leads to long devices—hundreds of microns to tens of millimeter. This is not practical for many applications and so many have looked into resonant structures to reduce the modulator size. The principle is simple—in a resonant cavity, the light will remain trapped, bouncing or circulating around for a time much greater than L/c, where L is some characteristic dimension of the device. In this section, we focus on a popular structure—the ring resonator [16,17,21,22]—but many other designs are possible, for example, a photonic crystal cavity [28].

A resonator is popularly characterized by its "Q" factor, which can be defined as the photon lifetime divided by the optical period. A ring resonator has a roundtrip time of

$$t_{\text{round}} = \frac{2\pi R}{c}\mu \tag{38.19}$$

where μ is the characteristic refractive index, R is the ring radius. The photon lifetime of a cavity for optical frequency f is Q/f. This means that a ring resonator can increase the time spent in the ring by a factor of

$$\frac{Q\lambda_0}{2\pi R\mu} \tag{38.20}$$

This gives the modulator more time to change the phase of the signal, and allows the modulator to be shrunk be a corresponding factor. The disadvantage is that the ring resonator optical bandwidth is reduced to f/Q, making it sensitive to small changes in input wavelength.

A typical resonator configuration is shown in Figure 38.16 (left). This design has only one tangential waveguide and will act as a phase modulator. If a second tangential waveguide is added (Figure 38.16, right) then the modulator will direct the light into this when in resonance.

The high Q lowers the modulation speed of the device as well as its optical bandwidth. Figure 38.17 shows a PicWave [14] simulation of an eye diagram for a 20-μm-diameter silicon ring resonator modulator driven in carrier depletion mode with a 20 Gb/s NRZ bit pattern. Notice the overshoot caused by the high Q of the cavity, in this case over 6000. In practice, this ringing would be filtered out by a low-pass filter on the detector.

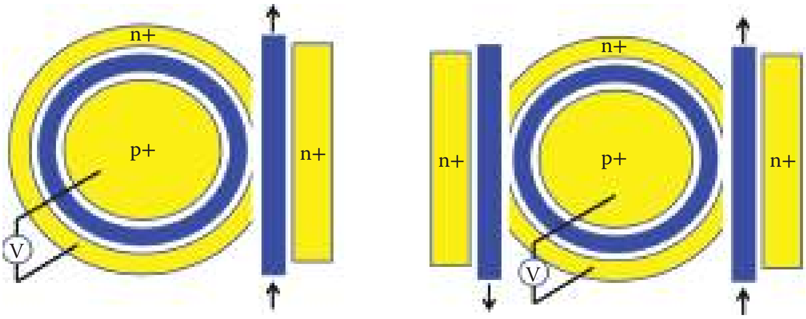

FIGURE 38.16 (Left) A silicon ring resonator modulator. The waveguides in blue (dark) are surrounded by electrodes imposing a reverse bias on the p-n junction (depletion-mode modulator). This design is a phase modulator. (Right) An amplitude modulator.

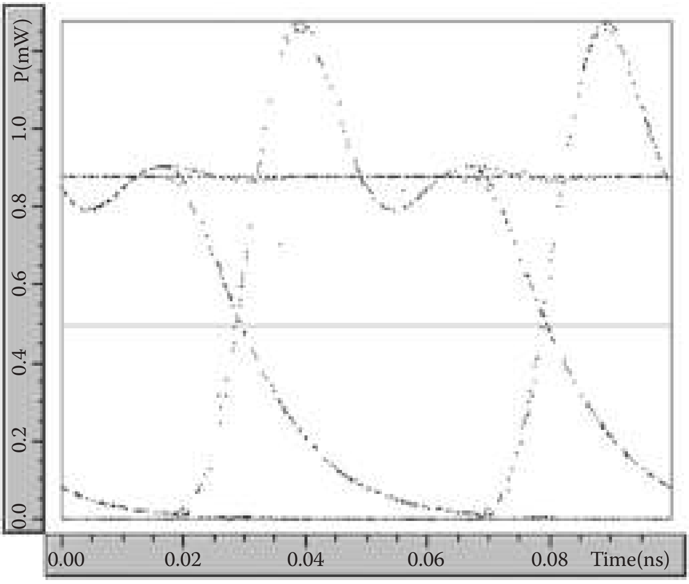

FIGURE 38.17 Eye diagram of a 20-μm-diameter silicon ring resonator modulator. The overshoot is caused by the high Q of the cavity.

39.1 Introduction

Solar cells convert the energy of the sun light to electricity. It is an optical to electrical energy conversion. In principle, they make use of the photovoltaic (PV) effect, i.e., the generation of a potential difference between two electrodes under illumination. It was firstly observed by A. E. Becquerel (Becquerel, 1839) and practically implemented in a solar cell at Bell Laboratories in the United States (Chapin et al., 1954). Today it is believed that PV energy generation will be a part of the world's base of energy supply established in the twenty-first century. Conservative estimates by the International Energy Agency (IEA) show a share of the world electrical energy generation of about 1% nowadays to about 16% in 2050 (IEA, 2014). This would correspond to a yearly energy generation of about 6300 TWh compared to slightly more than 200 TWh today.

Looking back on the past decades, we can see that the development in solar research and industry was very fast and economically successful, which enabled such a bright perspective for solar electricity. The price for solar modules reduced with increasing manufactured PV module capacity following a power-law relation: the so called PV learning curve could be established which is shown in Figure 39.1.

For example, the price of solar modules decreased by about 80% between the years 2008 and 2015. About 1000 GW module shipments may be reached in 2024 for 10% market growth, or even in 2021 for 30% market growth, which corresponded to the market development in the past 15 years. Those cost reductions

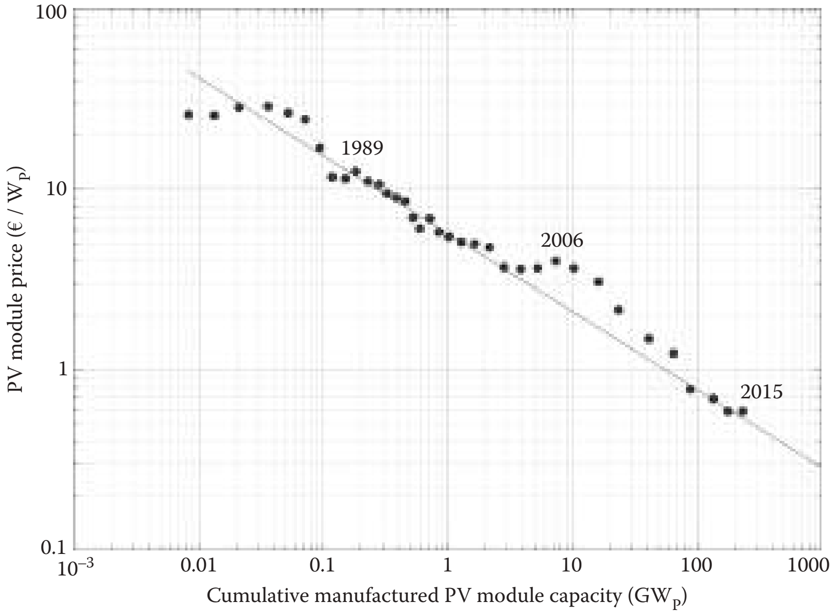

FIGURE 39.1 PV learning curve (Fraunhofer ISE, 2013; IEA, 2014; pvXchange, 2016) and a fit of a power law model to the years 1990–2000 and 2012–2015. In between the years 2000–2010, there was a shortage on raw silicon which slowed down the price reduction.

result largely from economies of scale and technological improvements. In 2015, the limit of 200 GW-shipped solar modules was exceeded, and the same volume is expected to be the future world production capacity to maintain the global solar energy supply in the twenty-first century starting from 2025 (IEA, 2014).

The current solar cell production is dominated by wafer-based crystalline silicon (c-Si) solar cells, which make about 90% of the market (ITRPV, 2015) and only 10% are thin-film technologies based mainly on cadmium telluride (CdTe) and copper indium gallium diselenide (CIGS). That is why the author focuses on the c-Si technology within this chapter.

Looking closely on c-Si, the shares of different wafer technologies that are applied nowadays are shown in the upper graph of Figure 39.2 (ITRPV, 2015), where mainly boron-doped p-type material is used (95%). The cast silicon materials multicrystalline (mc) and high-performance multicrystalline (HPmc-Si) currently make up to over 65%, whereas monocrystalline, mainly Czochralski (Cz), make 35%.

The share of different solar cell technologies is shown in the lower graph of Figure 39.2, where the main product currently is the full-area back-surface-field (BSF) solar cell (Mandelkorn and Lamneck, 1972), whereas the passivated emitter and rear cell (PERC) technology (Blakers et al., 1989) shows increasing market shares in the near future (ITRPV, 2015). The passivated emitter and rear totally diffused solar cell (PERT) (Zhao et al., 1999), the Si-heterojunction (SHJ) solar cell (Tanaka et al., 1992) and the back contacted solar cells—mainly interdigitated back contact solar cells (IBC) (Lammert and Schwartz, 1977)—are expected to play a minor role in the coming years but may be candidates for future high-efficiency solar cells with higher market shares (ITRPV, 2015). The structure of these different solar cells is shown in Figure 39.3.

This chapter gives a general overview about the working principle and basic models of solar cells. The view will be extended to the energy yield delivered by solar cells under real world conditions, i.e., the view will be extended to solar cells working in solar modules and the corresponding cell demands. Examples will

(1998). Additionally, the author would like to refer to the free online resources for PV engineers and scientists PVEducation (PVEDUCATION.ORG, 2016) and PV Lighthouse (PV Lighthouse, 2016).

39.2 The PV System

The solar cell is only a part, even so the functional device, of a full PV system. Such systems may be grid-connected as shown in Figure 39.4, or stand-alone systems, which means that all produced electricity is consumed locally. Those stand-alone PV systems are good options for rural areas of developing countries and special applications (e.g., parking meter). However, in comparison, grid-connected systems produce nowadays and will produce in the future a higher share of electricity. A grid-connected system consists of solar modules, which contain the solar cells. These modules are typically connected in series (called module string) to an inverter. Those inverters first do Maximum Power Point Tracking (MPPT) of the module strings and secondly convert the direct current produced by solar cells in alternating current. The inverter is connected to the load and to the electricity grid via an AC isolation switch and via an import/export electricity meter (compare Figure 39.4).

A current trend for grid-connected systems is the combination with storage systems. It increases energy self-consumption, as it is expected that during noon an excess of solar energy is produced. This excess energy can then be stored and used during times without irradiation. The trend will be enhanced, as the price for electricity is decreasing more and more at noon time when more solar power plants are connected to the grid. So the storage system will help for grid stabilization as PV electricity is a fluctuating energy challenging the electricity grid in the future. Those battery PV systems are controlled by an energy management system (EMS) which regulates production, load, storage, and grid connection (compare Figure 39.4).

Looking in more detail at the structure of a solar module as shown in Figure 39.5, one can see that solar cells are basically embedded between glass and plastics.

A typical solar module contains 60 solar cells on an area of approximately 1.7 m^2. They are connected in series by tabbing ribbons to strings of 20 cells while bus ribbons interconnect the three cell strings. Those cell strings are connected in parallel by a bypass diode which accounts for lower power losses during shading conditions. Finally, the bus ribbons are connected to the junction box, where cables with connectors go out.

Solar modules are made to produce electricity for at least 20–30 years; hence all used materials have to withstand changing environmental conditions. Solar glass, that in most cases is low-iron rolled glass or float glass, is situated on the side facing the sky and has to withstand rain, hail and snow. Besides, the front glass guarantees mechanical stability against wind and snow load. It may be manufactured with an antireflection coating (ARC) and/or textured, i.e., with a structured front surface for improved light trapping. The rear side is typically covered with polyethylene terephthalate (PET) polymer backsheet which features moisture resistance and electrical isolation. If replaced by another glass to produce a glass-glass module, the solar

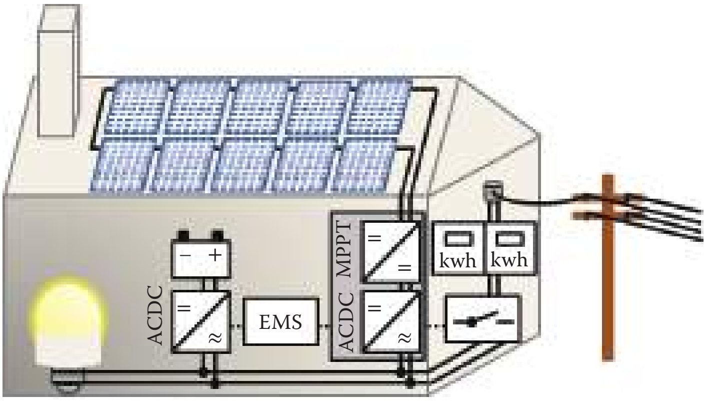

FIGURE 39.4 Schematic of a PV system with solar modules, cables, inverter, battery energy managements system (EMS), battery, load, AC isolation switch, and import/export electricity meter.

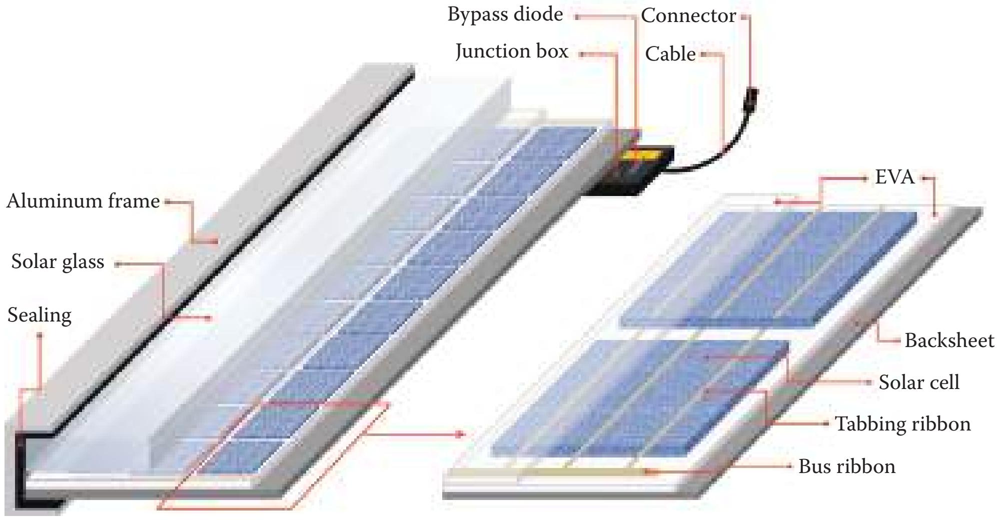

FIGURE 39.5 Structure of a solar module. EVA, ethylenvinylacetate.

module lifetime increases by about 5–10 years. Finally, the solar cells are embedded between the solar glass and the backsheet in Ethylenvinylacetate (EVA) as an encapsulant. It is a polymer which cross-links at about 150°C during manufacturing. Solar modules are sealed at the edges with silicone and an aluminum frame.

39.3 The Solar Spectrum

Our sun is basically a fusion power plant which emits electromagnetic radiation from its surface, called photosphere, into the solar system. It has a spectrum similar to a blackbody with a temperature of 5777 K, which is shown in Figure 39.6.

The light intensity reaching the planet earth is reduced by a factor of 2.17×10^{-5} due to geometrical considerations. The factor is the square of the suns radius divided by the square of the distance sun–earth. The resulting spectrum above the earth's atmosphere is shown in Figure 39.6 denoted as AM0, where AM stands for air mass index and the "zero" denotes that the light doesn't travel through the earth's atmosphere. This extraterrestrial solar spectrum AM0 has an irradiance of 1366.1 $\mathrm{W/m^2}$ as defined within (ASTM E490-00a, 2014), which is called the solar constant. The latest measured value is 1360.8 $\mathrm{W/m^2}$ (Kopp and Lean, 2011). This spectrum is relevant for solar cell power measurements for space applications.

Light traveling through the atmosphere faces absorption, scattering, and reflection effects which change the spectrum and the irradiance as shown schematically in Figure 39.7.

Absorption in the earth's atmosphere takes place in its molecules: ozone, oxygen, water vapor, carbon dioxide, nitrogen dioxide. Scattering in the atmosphere takes place at particles that are smaller than the wavelength of the light (Rayleigh scattering, e.g., N_2, O_2 molecules) and which are larger than the wavelength of the light (Mie scattering, e.g., aerosol particles, cloud droplets). The third mechanism is reflection of the light in the atmosphere, mainly at the clouds, and finally at the ground. This introduces a direct, a diffuse, and a ground-reflected component of irradiance on the module plane. The diffuse component describes all light coming from any region of the sky, mainly Rayleigh-scattered light which we see as blue sky on sunny days.

The standard spectrum AM1.5g is the result of light passing the earth's atmosphere approximately on a very sunny day and it is shown in Figure 39.6. The air mass index AM defines the direct optical path length through the atmosphere of the earth. Thus, AM1.5 is one and a half times the path length; "g" stands for

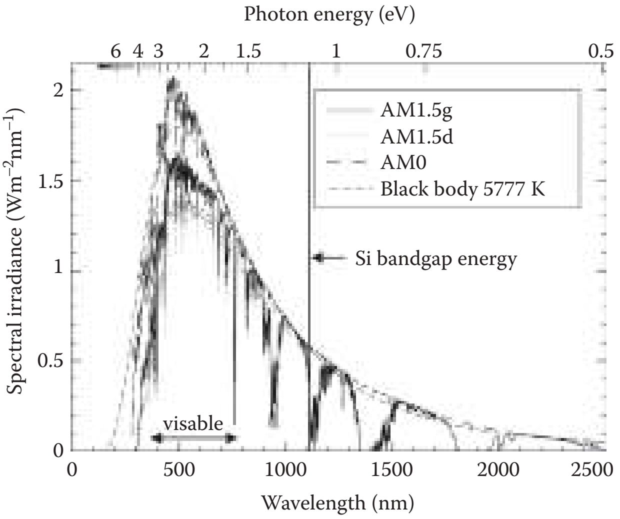

FIGURE 39.6 Comparison of different spectra: blackbody spectrum with a temperature of 5777 K, extraterrestrial spectrum AM0 (ASTM E490-00a, 2014), reference spectra AM1.5g and AM1.5d (ASTM G173-03, 2012) for global and direct solar spectral irradiance at AM1.5, respectively.

global, i.e., with direct and diffuse light. The spectrum AM1.5d, which is also shown in Figure 39.6, is only the direct component of the AM1.5g and is used to measure solar cells for concentrated PV (CPV) applications.

39.4 Real Operating Conditions of Non-concentrated Solar Cells and Modules

The output power of a solar system, typically expressed in "Watt-peak" (W_P), and the efficiency of a solar system or solar components like solar cells or solar modules are determined by a standardized measurement of the current–voltage (I-V) characteristic under the "Standard Test Conditions" (STCs), i.e., under a light intensity of 1000 W/m^2 (one-sun), an ambient temperature of 25°C and the standardized spectrum AM1.5g (ASTM G173-03, 2012) which may altogether correspond approximately to a very sunny summer day in the morning on a 37° sun facing tilted surface with low ambient temperature.

Unfortunately, those environmental conditions do not occur very often. During the year and day-time deviations from the reference efficiency under STC are observed and the efficiency of the solar system changes due to a severe number of effects:

- Efficiency decrease due to module heat generation above 25°C
- Efficiency decrease due to low light/partial load condition (e.g., cloudy weather)
- Reflection losses due to incident light under increased angle of incidence (AOI) between the module and the sun
- Decreased or increased efficiency due to the change of the spectrum of the incident light
- Mismatch loss due to interconnection of cells in a module and solar modules in a PV system with different I-V characteristics
- Losses due to soiling and snow
- Losses due to shading
- Losses due to interconnection and (bypass) diode failures
- MPPT failure of the MPP tracker
- Conversion losses and self-consumption of the inverter (stand-by loss)
- Energy yield loss due to differences in real, measured and labeled module power
- Degradation, i.e., efficiency decrease over time due to environmental stress load

The effect of efficiency degradation of solar modules happens mainly due to mechanical stress and moisture resulting in corrosion, discoloration, delamination, breakage, and cracking cells (Jordan and Kurtz, 2013), but also due to solar cell degradation resulting from the formation of defects within the silicon wafers under illumination, e.g., the boron-oxygen-related defect (Schmidt et al., 1997). Another degradation mechanism may occur in solar modules under high potential (Pingel et al., 2010), which is called potential-induced degradation (PID). PID results in a low shunt resistance of the module and can decrease the output power down to zero. Nevertheless, the solar module lifetime exceeds 20–25 years maintaining typically at least 80% of its initial efficiency or for a glass-glass module even more than 30 years. Thus a solar module is one of the longest lasting products for electricity generation that does not need maintenance.

A parameter that considers all the real world influences on a PV system is the performance ratio PR, as defined by

$$PR = \frac{\text{real energy yield}}{\text{ideal energy yield}} = \frac{W_{\text{SP}}}{H_{\text{sun}} \times A_P \times \eta_{\text{STC}}} \tag{39.1}$$

PR is defined as the actual energy yield of a PV system W_{SP} related to the incoming sun irradiation H_{sun} on the array area A_{P} converted by the solar system efficiency under STC η_{STC} over a time interval of months/years. Also a wide spread parameter for PV system assessment is the specific or final system yield Y_{f} in kWh/kWp, as defined by Equation 39.2, which allows to compare the energy production for different systems at similar locations. Typical values are in the range of 500–2500 kWh/kWp.

$$Y_{\text{f}} = \frac{W_{\text{SP}}}{P_{\text{syst}}} \tag{39.2}$$

39.4.1 Irradiation

The frequency with which STC applies in real world is negligible. For a better understanding of which environmental conditions are more typical for a solar system, exemplarily three geographical locations are chosen for further visualization within this chapter, which are situated in middle-Europe (Halle, Germany), southern-Europe (Almeria, Spain) and in tropical climate close to the Equator (Brazzaville, Republic of the Congo).

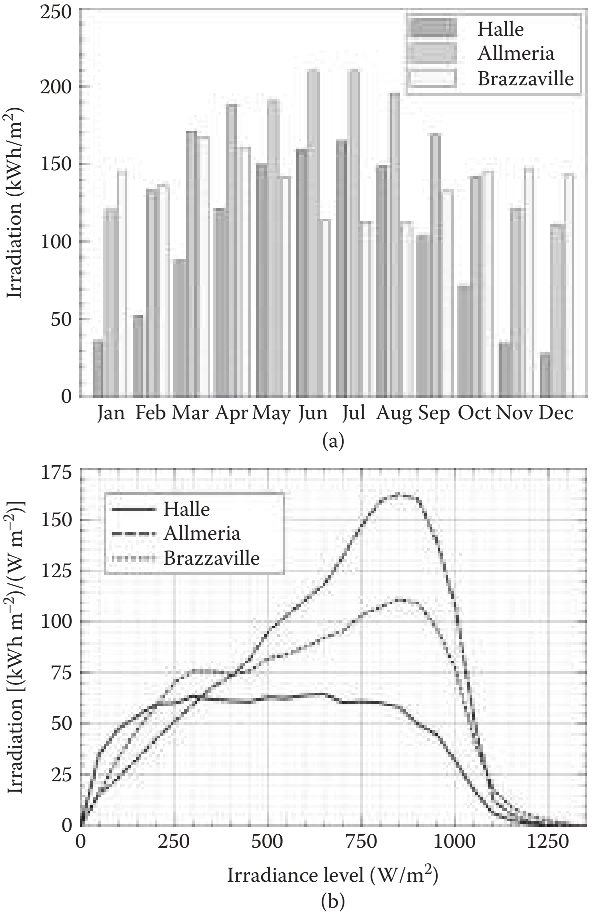

FIGURE 39.8 (a) Comparison of different irradiation conditions (Meteotest, 2008) per month, and lower graph versus in-plane irradiance level. (b) A histogram in steps of 50 W/m^2 per irradiance level bin where the frequency is multiplied by the mean irradiance of each bin.

An overview about the applying in-plane irradiation conditions, i.e., irradiation on the tilted surface, are shown in the upper graph of Figure 39.8 per month and in the lower graph versus irradiance level.

The geometric considerations concerning sun light hitting a tilted surface may be found in references (Duffie and Beckman, 2013; Quaschning, 2005). The yearly solar energy yield, i.e., in-plane irradiation, is 1159 kWh/m^2 for Halle, 1961 kWh/m^2 for Almeria and 1657 kWh/m^2 for Brazzaville for tilted surfaces having tilted angles of 30° for Halle and Almeria, and 10° for Brazzaville, respectively.

Meteorological data may be found worldwide at NASA Surface Meteorology and Solar Energy Data Set (NASA, 2016) and using the software Meteonorm (Meteotest, 2008), for EU at PVGIS EU Joint Research Centre (JRC, 2016), and for US at National Renewable Energy Laboratory (NREL, 2016).

39.4.2 Temperature

The illumination of solar modules does not only generate electricity, but also heat. The main reasons are the heat generation of the solar cells due to thermalization of charge carriers and parasitic absorption within the module of photons with higher wavelength than the bandgap of the semiconductor. A typical solar cell operating temperature increases linearly with the in-plane irradiance G_I above ambient temperature.

As commercial solar modules have a very similar structure as shown in Figure 39.5, they have comparable thermal properties and heat in a similar way. The thermal properties are measured in a standardized way determining the "Nominal Operating Cell Temperature" (NOCT) (IEC 61215, 2005) of the solar module under 800 W/m^2 light intensity, 20°C ambient temperature, AM1.5g spectrum, and 1 m/s wind velocity, which results in typical NOCT = 45°C ± 3°C.

For a better understanding of the system efficiency losses due to different operating temperatures deviating from 25°C (STC), an annual average operating temperature T_{ann} is calculated from the meteorological data set shown in Figure 39.8. The solar cell operating temperature T_{Cell} is calculated by (Ross and Smokler, 1986)

$$T_{\text{Cell}} = T_{\text{amb}} + (\text{NOCT} - 20°\text{C})\frac{G_I}{800\frac{\text{W}}{\text{m}^2}} \tag{39.3}$$

This model represents a standard roof top PV system installation. For an open-rack mounting condition lower T_{Cell} can be expected whereas for building integrated installations higher T_{Cell} is expected (Garcia and Balenzategui, 2004).

Assuming that a PV system only depends on irradiation and different ambient temperatures, the annual average (irradiance weighted) cell operating temperature T_{ann} is calculated by

$$T_{\text{ann}} = \frac{\int^{1a} P(t) \times T_{\text{Cell}}(t)\text{d}t}{\int^{1a} P(t)\text{d}t} = \frac{1}{W_{\text{SP}}} \int^{1a} P(t) \times T_{\text{Cell}}(t)\text{d}t \tag{39.4}$$

Exemplarily, the monthly average operating temperature is calculated and shown in Figure 39.9, assuming a *NOCT* of 45°C and applying Equations 39.3 and 39.4 to the meteorological data sets.

The annual average cell operating temperature for the selected locations are those of 32.0°C for Halle, 42.9°C for Almeria, and 47.7°C for Brazzaville, respectively. Hence Almeria and Brazzaville are close to the *NOCT* = 45°C, which confirms that NOCT is a relevant environmental condition for many locations. Assuming that the relative temperature coefficient of the efficiency of a typical c-Si solar cell is $-0.4\%_{\text{rel}}/°\text{C}$, an energy yield loss compared to STC may be calculated based on the annual average cell operating temperatures. For Halle $(32.0°\text{C} - 25.0°\text{C}) \times -0.4\frac{\%_{\text{rel}}}{°\text{C}} = -2.8\%_{\text{rel}}$ may be expected, for Almeria $-7.2\%_{\text{rel}}$, and for Brazzaville $-9.1\%_{\text{rel}}$, respectively.

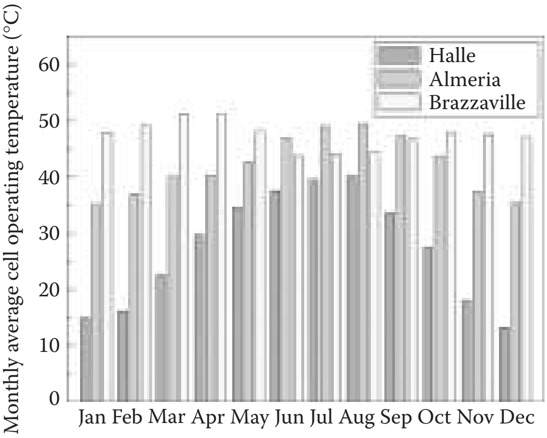

FIGURE 39.9 Monthly average (irradiance weighted) cell operating temperature per month for the locations Halle, Almeria, and Brazzaville.

39.5 Solar Cell Optics

In the field and under real operating conditions, solar cell's optical behavior is mainly determined by the optics of a solar module. In more detail, it strongly depends on the optics of the first medium and its surface structure facing the air (Winter et al., 2014), which is typically the solar glass. During year and day time, sun light appears under different oblique incidence to the module. An angle of incidence (AOI) θ can be defined, which is the angle between the sun's rays and the module normal. Light reaching the module's surface at an angle is spread out over a larger area, thus reduces the (direct) irradiance on the tilted plane following a cosine relation, as shown in Figure 39.10, described by:

$$G_{\mathrm{direct}}(\theta) = G_{\mathrm{direct}}\left(0^\circ\right) \times \cos(\theta) \tag{39.5}$$

The first interface air–glass may be simply described by the Fresnel equations and Beer–Lambert–Bouguer and Snell's laws (Duffie and Beckman, 2013), which are in general wavelength dependent. The angle of refraction θ_r is therefore

$$\theta_r = \arcsin\left(\frac{n_1}{n_2}\sin(\theta)\right) \tag{39.6}$$

where $n_1 = 1$ and $n_2 = 1.52$ are the refractive indices of air and solar glass, respectively. The angle-dependent transmission of such system is approximated by Equation 39.7 considering both reflective losses at the interface and absorption losses within the glass (Duffie and Beckman, 2013).

$$\left(A_{\mathrm{opt}}T_{\mathrm{opt}}\right)(\theta) = A_{\mathrm{opt}}\left(1 - R_{\mathrm{opt}}\right) = e^{-(KL/\cos\theta_r)}\left[1 - \frac{1}{2}\left(\frac{\left(\sin\left(\theta_r - \theta\right)\right)^2}{\left(\sin\left(\theta_r + \theta\right)\right)^2} + \frac{\left(\tan\left(\theta_r - \theta\right)\right)^2}{\left(\tan\left(\theta_r + \theta\right)\right)^2}\right)\right] \tag{39.7}$$

where $K = 4\ \mathrm{m}^{-1}$ may be assumed for the extinction coefficient and $L = 2$ mm for the thickness of the glass (Duffie and Beckman, 2013).

The calculation of the product of optical absorption and transmission through the solar glass ($A_{\mathrm{opt}}T_{\mathrm{opt}}$) approximates here the angle-dependent losses of the solar module, which is defined as the incident angle modifier (IAM). However, *IAM* accounts for all angular and spectral losses due to increased absorption

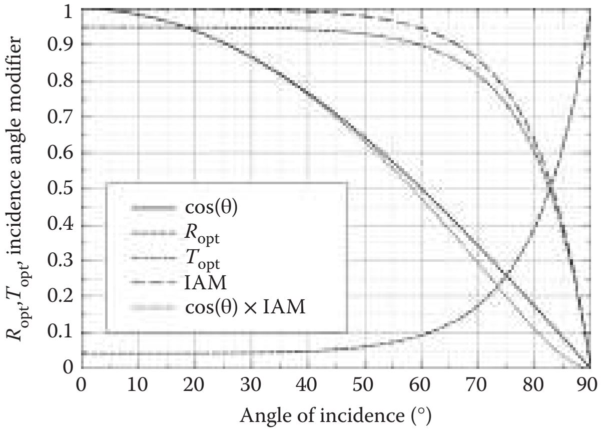

FIGURE 39.10 Cosine, optical reflection, and transmission ($n_1 = 1$ for air and $n_2 = 1.52$ for glass), incidence angle modifier (IAM), angle-dependent losses of a solar module versus angle of incidence.

within the EVA and for geometrically different, wavelength-dependent light propagation under oblique incident, i.e., multiple reflections at the cell or the backsheet. *IAM*, also shown in Figure 39.10, is used to correct the incoming direct irradiance G_{direct} on the tilted module plane as derived in Equation 39.8. The indirect irradiance component may be corrected in a similar approach.

$$G_{\text{direct}}(\theta) = G_{\text{direct}} \times \cos\theta \times IAM(\theta) = G_{\text{direct}} \times \cos\theta \times \frac{\left(A_{\text{opt}}T_{\text{opt}}\right)(\theta)}{\left(A_{\text{opt}}T_{\text{opt}}\right)(0^\circ)} \tag{39.8}$$

Calculations for the angular-dependent irradiation losses over 1 year using Equations 39.5 through 39.8 and the meteorological data sets, as shown in Figure 39.8, result in $-1.3\%_{\text{rel}}$ for Halle, $-1.3\%_{\text{rel}}$ for Almeria, and $-0.9\%_{\text{rel}}$ for Brazzaville.

Latest developments of solar glass lead more and more to the introduction of ARCs and partially deeply structured (textured) glass, which improves the module optics.

The same concepts are also applied for solar cell optic optimization. ARCs for solar cells, as drawn in Figure 39.11, are typically applied as a single layer of silicon-nitride SiN_X films of about 75 nm thickness and a refractive index of about 2, whereas its optimum is slightly lower against air and slightly higher if optimized for the use in a module.

Those thin film layers may be well modeled by the transfer matrix method, which considers oblique incidences, absorbing media, coherent light, and even assemblies of thin films (e.g., double ARC) (Macleod, 2010). The second optimization strategy is to apply a texture on the front side of the solar cell, which increases the chance that reflected light reaches again the solar cell surface a second or even more times as shown in Figure 39.11. Most relevant textures for industrial application are random pyramids for monocrystalline (Cz) cells and isotexture, which forms bowl-like structures, for mc cells. Both are produced by wet chemical etching. Additional benefits of texturing arise because light is coupled into the silicon under an angle. First, this increases the chance of a photon to be absorbed close to the surface, second the path length for absorption is increased within the semiconductor and thirdly such photons may reach the rear side under the critical angle of total internal reflection. This internal light trapping may be even improved further if the rear side has properties of a back reflector, as reflected light of wavelengths close to the bandgap energy gets the chance to be absorbed on the way there and back (at least double length) within the semiconductor. Those back reflectors are, e.g., full area Aluminum layers for a BSF solar cell or dielectric layer stacks for PERC solar cells. Note that semiconductors having a direct bandgap (e.g., GaAs, CIGS, CdTe) may be fabricated with much smaller absorber thickness compared to, e.g., silicon with an indirect bandgap, and are called thin film solar cells.

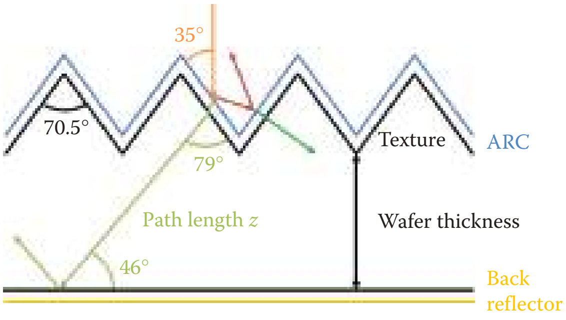

FIGURE 39.11 Schematic of light trapping within a solar cell with antireflection coating (ARC) and a random pyramid texture. Note that the schematic is not to scale, as a typical side length of such pyramid is about 5 μm and a wafer thickness is about 200μm.

39.5.1 Photogenerated Current

A way to model light-induced photocurrent of solar cells, as shown in Figure 39.11, is to use ray-tracing, which is a method to calculate the path of a photon through the solar cell considering its geometry. The light propagation may be calculated at surfaces and interfaces as necessary, e.g., using Fresnel equations. Raytracing software for solar cells are, e.g., Sunrays (Brendel, 1994), TCAD Sentaurus Device (Synopsys, 2016) and for solar modules, e.g., Daidalos (Holst et al., 2013). Also wide spread in the PV community is the usage of the simulation tool PC1D (Rover et al., 1985), which can also analytically calculate solar cell optics with texture and ARC.

The absorption of photons within the active semiconductor leads to the creation of electron–hole pairs, i.e., to a current generation. This photogenerated current density j_{gen} is not influenced by front contact shading and recombination losses and hence can be treated as the maximum current potentially extracted from the solar cell described by

$$j_{\mathrm{gen}} = -q \int_{0}^{\infty} A_{\mathrm{opt}} \Big[E_{\mathrm{ph}} \big) \, \mathrm{d}j_{\mathrm{ph}}(E_{\mathrm{ph}}) \tag{39.9}$$

where q is the elementary charge, E_{ph} is the photon energy and j_{ph} is the photon flux. Assuming $A_{\mathrm{opt}}(E_{\mathrm{ph}} \geq E_{\mathrm{g}}) = 1$, Equation 39.9 solves to

$$j_{\mathrm{gen}} = -q \int_{E_{\mathrm{g}}}^{\infty} \mathrm{d}j_{\mathrm{ph}}(E_{\mathrm{ph}}) \tag{39.10}$$

The optical absorption in silicon is described by its absorption coefficient α which is shown in Figure 39.12.

The maximal achievable photogenerated current density for c-Si is about 46 mA/cm^2 for AM1.5g reference spectrum. Photons with more energy than the bandgap energy E_{g} quickly loose this "extra" energy to the lattice atoms in a process called thermalization. Photons with lower energy than E_{g} are not able to excite any electron from valence to conduction band and are not absorbed under the creation of an electron–hole pair.

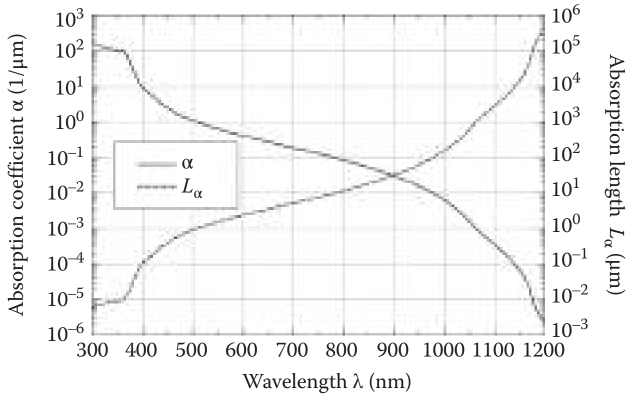

FIGURE 39.12 Absorption coefficient α and absorption length $L_\alpha = 1/\alpha$ for silicon at 300 K.

39.6 Conversion into Electrical Energy

The conversion of the optical energy of the sun light into electrical energy can be regarded in general in terms of particles in a two-level energy system. The particles are excited from their ground state to an excited state by illumination and carry the energy of the photon in the excited state. In general, the excited particles need to be extracted from the absorber into an external electrical circuit; otherwise recombination takes place which is the reverse reaction to excitation, also called generation. This is realized by the usage of selective contacts which only allow the excited particle to flow out at one side of the absorber, preventing the "overflow" of the absorber, which is the driving force. The excited particles flow into the external electrical circuit to perform work and then flow back into the absorber as relaxed particles through the other contact.

A possible realization for selective contacts is to create oppositely situated highly n- and p-type doped regions in the absorbing semiconductor for the respective contact, which is shown in the schematic of an illuminated semiconductor-based solar cell in Figure 39.13. Under illumination-free electrons and holes (excess charge carriers), introduced as excited particles, are generated in the conduction band and valence band, respectively. Thus the quasi-Fermi-levels of electrons E_{Fn} and holes E_{Fp} split in the semiconductor describing the energy distribution of electrons and holes by Fermi–Dirac statistics within the conduction and valence band, respectively. The Fermi levels of the majority carriers join at the surfaces at the respective metal contacts because the surface states exchange electrons very easily with the metal and maintain the same potential. The opposing doping at each contact results in three main effects. First, low minority carrier densities occur at the contacts due to the law of mass action and hence lead to almost zero contact recombination (selective contact). In consequence, only one kind of charge carrier is extracted. Second, it can result in ohmic contact behavior with sufficiently high doping close to the contact, which leads to low resistive losses at the contacts. Third, the creation of p-type and n-type regions in the semiconductor leads to the creation of a p-n junction with a SCR and a built-in potential, also called diffusion voltage, which is typically thought to be a necessity for solar cells, but it is not the "engine" of a solar cell (Wuerfel, 2005). Both carrier types are continuously created under illumination, and, e.g., under short-circuit condition electrons and holes flow out at their respective selective contacts as the reverse direction is blocked for them. Thus an excess of charge carriers is produced and the majority of excess charge carriers do not recombine before they diffuse along their concentration gradients. This creates a charge current through the solar cell. As charge current flows are the result of potential gradients, the behavior of solar cells is described below in this section in terms of potentials in more detail. Under an external forward bias, the difference of E_{Fn} in the n-type region and E_{Fp} in the p-type region correspond to the external voltage V, so that

$$E_{\mathrm{Fn}} - E_{\mathrm{Fp}} = qV \tag{39.11}$$

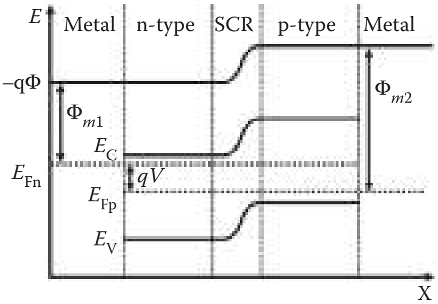

FIGURE 39.13 Schematic of the band diagram of an illuminated solar cell with two selective contacts with their respective metal work functions Φ_m separated by a p-n junction with a space-charge region (SCR) and the electrostatic potential Φ.

where q is the elementary charge. The forward bias reduces the built-in potential of the p-n junction. The driving forces of charge currents in a solar cell are the gradients of the quasi-Fermi-levels E_{Fn}/dx and E_{Fp}/dx, which are the gradients of the electrochemical potentials for electrons and holes, respectively. The electrochemical potential of electrons, which is constant in thermal equilibrium, is determined by the chemical potential $E_{\mathrm{C}} - E_{Fn}$ and the electrostatic potential $-q\Phi$:

$$E_{\mathrm{R}} - E_{Fn} = \left(E_C - E_{Fn}\right) - q\phi \tag{39.12}$$

where E_{R} is the reference potential. The absolute value of E_{R} is not relevant as only gradients of the potentials are of interest. The chemical potential describes the diffusion aspect of carrier transport due to a gradient in the carrier concentration whereas the electrostatic potential describes the force acting on charge carriers due to coulomb interaction and it is the drift aspect of charge carriers transport due to an electric field. Those two transport mechanisms have to be considered together, because diffusing mobile electrons and holes inherently carry a charge.

39.7 Modeling of Ideal *I–V* Characteristics

A PV solar cell can in first-order approximation be described in an equivalent circuit model as a photocurrent generator in parallel with a diode. It corresponds to the single diode equation which will be derived below, in a similar way to the reference (Green, 2003). In order to derive the model, the following assumptions are made: infinite thickness of the absorber, negligible contact resistances, zero contact recombination, zero surface recombination, low injection condition, i.e., the excess charge carrier density is much smaller than the doping density ($\Delta n \ll N_{\mathrm{dop}}$). Under open-circuit condition, there is not a charge carrier flow (no current) into the external circuit resulting in the recombination of all generated charge carriers in the solar cell. Thus the diode equation can be determined from the net recombination rate. The continuity equation for electrons in one dimension under steady-state condition is

$$q\frac{\partial n}{\partial t} = 0 = \nabla \cdot j_{\mathrm{n}} + q\left(G_{\mathrm{n}} - U_{\mathrm{n}}\right) = \nabla \cdot j_{\mathrm{n}} + qG - q\frac{\Delta n}{\tau_{\mathrm{n}}} \tag{39.13}$$

where n is the electron carrier density, j_{n} is the electron current density, G_{n} is the generation rate, U_{n} is the recombination rate and τ_{n} can be interpreted as the average time after which an excess minority carrier recombines. Solving Equation 39.13 for j_{n} leads to

$$j_{\mathrm{n}} = q\int_{0}^{L_{\mathrm{n}}} \left[G_{\mathrm{n}} - q\frac{\Delta n}{\tau_{\mathrm{n}}}\right] \mathrm{d}x = qG_{\mathrm{n}}L_{\mathrm{n}} + q\int_{0}^{L_{\mathrm{n}}} \frac{\Delta n}{\tau_{\mathrm{n}}}\mathrm{d}x \tag{39.14}$$

where L_n is the diffusion lengths for electrons. The relation between carrier lifetime and diffusion length for electrons is determined by the electron diffusion coefficient D_{n}:

$$\tau_{\mathrm{n}} = \frac{L_{\mathrm{n}}^{2}}{D_{\mathrm{n}}} \tag{39.15}$$

Respective equations are derived for holes as minority carriers relevant for the n-type region. The excess charge carrier density Δn may be derived from the law of mass action at all dopant and injection conditions from

$$np = \left(N_{\mathrm{D}} + \Delta n\right)\left(N_{\mathrm{A}} + \Delta n\right) = n_{\mathrm{i,\,eff}}^{2} e^{\left(\frac{E_{\mathrm{Fn}} - E_{\mathrm{Fp}}}{k_{\mathrm{B}}T}\right)} = n_{\mathrm{i,\,eff}}^{2} e^{\left(\frac{qV}{k_{\mathrm{B}}T}\right)} \tag{39.16}$$

where p is the hole concentration, N_{D} is the donor concentration, N_{A} is the acceptor concentration, k_{B} is the Boltzmann constant, T is the temperature and $n_{\mathrm{i,eff}}$ is the effective intrinsic carrier density (Altermatt et al., 2003). The latter depends on the intrinsic carrier concentration n_{i} and the bandgap narrowing (BGN) ΔE_{g}, which is temperature-, doping- and injection-dependent (Schenk, 1998) and is defined by

$$n_{\mathrm{i,eff}}^2 = n_{\mathrm{i}}^2 e^{\left(\frac{\Delta E_{\mathrm{g}}}{k_{\mathrm{B}}T}\right)} \tag{39.17}$$

For a p-type semiconductor under low-level injection, i.e., $\Delta n \ll N_{\mathrm{A}}$, Equation 39.16 reduces to

$$\Delta n \approx \frac{n_{\mathrm{i,eff}}^2}{N_{\mathrm{A}}}\left(e^{\left(\frac{qV}{k_{\mathrm{B}}T}\right)} - 1\right) \tag{39.18}$$

Substituting Equations 39.15 and 39.18 in Equation 39.14 for electrons and holes and integrating over x from L_{n} to L_{p} computes to the total current density:

$$j(V) = j_{\mathrm{n}} + j_{\mathrm{p}} = qG\left[L_{\mathrm{n}} + L_{\mathrm{p}}\right) + \left(\frac{qn_{\mathrm{i,eff}}D_{\mathrm{p}}}{N_{\mathrm{D}}L_{\mathrm{p}}} + \frac{qn_{\mathrm{i,eff}}D_{\mathrm{n}}}{N_{\mathrm{A}}L_{\mathrm{n}}}\right)^{\mathfrak{J}}\left(e^{\left(\frac{qV}{k_{\mathrm{B}}T}\right)} - 1\right) \tag{39.19}$$

This can be simplified to the single diode equation

$$j(V) = j_{\mathrm{SC}} + \left[j_{0\mathrm{e}} + j_{0\mathrm{b}}\right)\left(e^{\left(\frac{qV}{k_{\mathrm{B}}T}\right)} - 1\right) = j_{\mathrm{SC}} + j_0\left(e^{\left(\frac{qV}{k_{\mathrm{B}}T}\right)} - 1\right) \tag{39.20}$$

where j_{SC} is the short-circuit current density, which differs from the photogenerated current density j_{gen}, as not all generated charge carriers are collected because of their finite diffusion lengths. The carriers recombine before they reach the p-n junction. The saturation current density j_0 can be separated in the contribution of the n-type region called emitter saturation current density $j_{0\mathrm{e}}$ and in the contribution of the p-type region called base saturation current density $j_{0\mathrm{b}}$. A more realistic saturation current density of the base for a finite thickness of the solar cell and a non-zero surface recombination is defined by (Goetzberger et al., 1998)

$$j_{0b} = \frac{qn_{\mathrm{i,eff}}D_{\mathrm{n}}}{N_{\mathrm{A}}L_{\mathrm{n}}}G_{\mathrm{Fn}} \tag{39.21}$$

where G_{Fn} is the geometry factor considering the effective surface recombination velocity of the electrons S_n and the thickness of the base (p-type region) W_p:

$$G_{\mathrm{Fn}} = \frac{\cosh\left(\frac{W_{\mathrm{P}}}{L_{\mathrm{n}}}\right) + \frac{D_{\mathrm{n}}}{S_{\mathrm{n}}L_{\mathrm{n}}}\sinh\left(\frac{W_{\mathrm{P}}}{L_{\mathrm{n}}}\right)}{\frac{D_{\mathrm{n}}}{S_{\mathrm{n}}L_{\mathrm{n}}}\cosh\left(\frac{W_{\mathrm{P}}}{L_{\mathrm{n}}}\right) + \sinh\left(\frac{W_{\mathrm{P}}}{L_{\mathrm{n}}}\right)} \tag{39.22}$$

In Figure 39.14, an ideal solar cell I-V and power characteristic are shown, which are calculated using Equation 39.20 assuming $j_{\mathrm{SC}} = -40$ mA/cm^2, $j_0 = 100$ fA/cm^2, and $T = 25$°C.

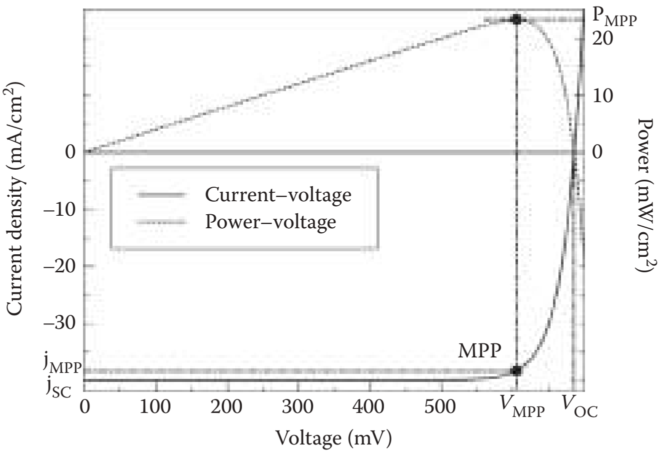

FIGURE 39.14 Example of solar cell current–voltage (I–V) and power characteristics. (MPP, maximum power point.)

39.7.1 *I–V* Parameters and Quantum Efficiency

In Figure 39.14, important output parameters of I–V and P–V characteristics can be extracted as there are: short-circuit current density $j_{SC}(V = 0\text{ V})$, open-circuit voltage V_{OC} ($j(V_{OC}) = 0\text{ mA/cm}^2$) and the maximum power point (MPP) ($P_{MPP}(V) = P_{max}$) with the current density and voltage at MPP j_{MPP} and V_{MPP}, respectively.

The short-circuit current density j_{SC} is the part of photogenerated current density j_{ph} which is collected by the p-n junction due to limited carrier diffusion length within the emitter and the base. A measure of this difference is the internal quantum efficiency (IQE). It is the relation between extracted charge carriers from the solar cell and generated charge carriers in the solar cell. The wavelength-dependent IQE(λ) can be derived from the measurable external quantum efficiency EQE(λ):

$$\text{IQE}(\lambda) = \frac{\text{extracted charge carriers}}{\text{generated charge carriers}} = \frac{\text{EQE}(\lambda)}{(1 - R_{opt}(\lambda) - A_{opt,par}(\lambda) - T_{opt}(\lambda))} \tag{39.23}$$

The EQE also considers optical losses due to reflection, transmission, and parasitic absorption $A_{opt,par}$ in, e.g., dielectric layers at front and rear side. It can be defined by the ratio:

$$\text{EQE}(\lambda) = \frac{\text{extracted charge carriers}}{\text{incident photons}} \tag{39.24}$$

The fill factor (FF) and the efficiency η are derived from the I–V characteristic. The FF is defined by

$$\text{FF} = \frac{j_{MPP}V_{MPP}}{j_{SC}V_{OC}} = \frac{P_{MPP}}{j_{SC}V_{OC}} \tag{39.25}$$

FF is always below 1 and is introduced to describe nonideal losses in the solar cell arising, e.g., due to series resistance losses as discussed in Section 39.8. The efficiency is calculated considering the irradiance G_I and the cell area A_{Cell}:

$$\eta = \frac{P_{MPP}}{G_I A_{Cell}} = \frac{\text{FF}\, j_{SC}V_{OC}}{G_I A_{Cell}} \tag{39.26}$$

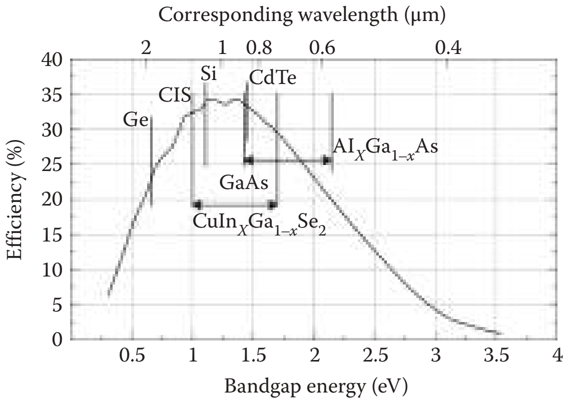

FIGURE 39.15 Dependence of a maximal achievable efficiency on the bandgap energy under an AM1.5g spectrum (1 sun) and a cell operating temperature of 300 K. Optimal bandgap energies of semiconductors are in the range of 1.0–1.5 eV. Established semiconductor absorber materials for solar cells are silicon (Si), Gallium-Arsenide (GaAs), Aluminum-Gallium-Arsenide ($Al_xGa_{1-x}As$), Germanium (Ge), CdTe, Copper-Indium-Diselenide (CIS), Copper-Indium-Gallium-Diselenide (CIGS).

39.7.2 Maximum Efficiency of Ideal Single Junction Solar Cells
